This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

MINERALOGY AND MINING.

Mine Accidents—Ventilation—Ore Dressing, Etc.

DESCRIPTIVE MINERALOGY.

DANA. Comprising the most recent Discoveries. Fifth edition. Almost entirely re-written and greatly enlarged. Containing nearly 900 pages 8vo, and upwards of 600 wood engravings. By Prof. J. D. Dana, aided by Prof. Geo. J. Brush. Including Appendices by Profs. Brush and E. S. Dana, completing the work up to 1882.....................8vo, cloth, $10 00

"We have used a good many works on Mineralogy, but have met with none that begin to compare with this in fullness of plan, detail, and execution."—*American Journal of Mining.*

THIRD APPENDIX TO DITTO.

DANA. Bringing the work down to 1882. By E.S. Dana. 8vo, limp cloth, 1 50

APPENDICES TO DESCRIPTIVE MINERALOGY, FIRST, SECOND, AND THIRD.

BRUSH, DANA. Completing the work to 1882. By Prof. Geo. J. Brush and E. S. Dana.....................................8vo, limp cloth, 2 00

MANUAL OF MINERALOGY AND PETROGRAPHY.

DANA Containing the Elements of the Science of Minerals and Rocks, for the use of the Practical Mineralogist and Geologist, and for Instruction in Schools and Colleges. By Jas. D. Dana, LL.D. Ninth edition. Revised throughout and enlarged. Illustrated with numerous woodcuts. 1890................12mo, cloth, 2 00

"The present issue is the 15th of the revised edition, the sale having reached nearly 15,000 copies. This is conclusive evidence of its value as a text-book, and for practical purposes."

A TEXT-BOOK OF MINERALOGY.

DANA. Based upon the System of Mineralogy of Prof. J. D. Dana. Embracing an extended Treatise on Crystallography and Physical Mineralogy. By Edw. S. Dana, Curator of Mineralogy, Yale College. With upwards of 800 woodcuts and one colored plate. Revised and enlarged edition. 1889. 8vo, cloth, 3 50

MANUAL OF DETERMINATIVE MINERALOGY.

BRUSH. DANA. With an Introduction on Blow-Pipe Analysis, (constituting the Determinative Part of Dana's Mineralogy). By Prof. Geo. J. Brush. Third edition, translated into the new system.
8vo, cloth, 3 50

INSTRUCTIONS FOR THE DETERMINATION OF ROCK-FORMING MINERALS.

HUSSAK. SMITH. By Dr. Eugen Hussak, Privat Docent in the University of Grau. Translated from the German by Erastus G. Smith, Prof. of Chemistry and Mineralogy, Beloit College. With 103 plates......................................8vo, cloth, 2 00

A MANUAL OF LITHOLOGY.

WILLIAMS. A practical work, intended to enable the student to classify at sight the more common species. By Edward H. Williams, Jr., Professor of Mining Engineering at Lehigh University, Pa...18mo, cloth, 75

A CATALOGUE OF MINERALS,

CHESTER. Alphabetically arranged, with their Chemical Composition and Synonyms. By Prof. A. H. Chester, Hamilton College.
8vo, cloth, 1 25

COMSTOCK LODE; ITS FORMATION AND HISTORY.

CHURCH. Illustrated with six plates and thirteen figures. By Prof. John A. Church, E.M., Ph.D ....4to, cloth, $5 00

THE COAL-MINES OF THE WESTERN COAST OF THE UNITED STATES.

GOODYEAR. By W. A. Goodyear ....12mo, cloth, 2 50

THE PRACTICE OF ORE DRESSING IN EUROPE,

KUNHARDT. By W. B. Kunhardt, Mining Engineer............8vo, cloth, 1 50

ACCIDENTS IN MINES,

SAWYER. Arising from the Falls of Roofs and Slides. Their Causes and the Means of Diminishing their Frequency, with Detailed Sections of Workable Seams and an Account of the System of Timbering in vogue in Staffordshire Coal-field, and Applicable elsewhere. By Arthur R. Sawyer, of the Royal School of Mines, and one of H. M. Inspectors of Mines. With over 800 figures of illustrations, partly printed in colors. 8vo, cloth, 7 00

"This book should be in the possession of every person connected with the mining of coal."—*Mining Herald.*

"This book should be not only interesting to miners, but be found prolific of valuable treats and advice."—*Engineering News.*

PRACTICAL MINE VENTILATION.

WILSON. For the Use of Mining Engineers, Students, and Practical Men. With plates. By Eugene B. Wilson, M.E...16mo, cloth, 1 25

"It is the best book in the English language on the subject."—THOS. DAVIS, Derringer, Pa.

"We recommend it heartily to our mining community."—*Colliery Guardian*, London.

RESOURCES OF SOUTHWEST VIRGINIA.

BOYD. A book not only for the general reader, but for Geologists, Mineralogists, Engineers, and Scientists, written in a popular style, and particularly suited to citizens of Virginia. By C. R. Boyd, M.E. Illustrated by a fine topographical, geological, and geographical map, plates, etc............ ....8vo, cloth, 3 00

DITTO. Third edition, on lighter paper..........8vo, cloth, 2 50

THE MODERN HIGH EXPLOSIVES—NITRO-GLYCERINE AND DYNAMITE.

EISSLER. Their Manufacture, their Use, and their Application to Mining and Military Engineering; Pyroxyline or Gun Cotton, the Fulminates, Picrates, and Chlorates; also, the Chemistry and Analysis of the Elementary Bodies which enter into the Manufacture of the principal Nitro-Compounds. By Manuel Eissler, Mining Engineer. With many illustrative plates. 8vo, cloth, 4 00

"This volume supplies to the engineer, contractor, and the chemist precisely what they previously needed with regard to the explosive forces which they may be called upon either to supply or use."—*Mining Record.*

EXPLOSIVE COMPOUNDS AND ROCK DRILLS.

DRINKER. Giving properties of Modern Explosives, Principles of Blasting, and descriptions and uses of the various Rock Drills and Compressors, and forming a SUPPLEMENTARY VOLUME to the first edition of DRINKER'S TUNNELING. 4to, cloth, 5 00

PUBLISHED AND FOR SALE BY

of New York.

PREFACE.

The large size of this volume on Descriptive Mineralogy, exceeding by one-half the corresponding part of the preceding edition, is not without good reason.

In the first place, the long interval of fourteen years has elapsed since the last edition was published, and during this period the science has made great progress. Chemical researches have been carried forward in connection with almost every species, and analyses have been largely multiplied; and it is the plan of the work to be complete in this department, so far as to include all analyses. Crystallographic investigations also have been numerous and important. Moreover, the number of species has been much enlarged, and every part of the science has had accessions of facts.

In addition, a new feature has been given the work, in the systematic recognition and description of the *varieties* of species. The first edition of this Treatise, that of 1837, was written in the spirit of the school of Mohs. The multitudes of subdivisions into subspecies, varieties, and subvarieties, based largely on unimportant characters, which had encumbered the science through the earlier years of this century, and were nearly smothering the species, were thrown almost out of sight by Mohs, in his philosophic purpose to give prominence and precision to the idea of the species. Much rubbish was cleared away, and the science elevated thereby; but much that was necessary to a full comprehension of minerals in their diversified states was lost sight of. In the present edition an endeavor is made to give varieties their true place; and to insure greater exactness with regard to them, the original locality of each is stated with the description.

Further, the work has received another new feature in its historical synonymy. A list of synonyms has hitherto been mainly an index to works or papers on the species, and often without any regard to the original describer or description. Hausmann's admirable Handbuch (1847) is partly an exception. Leonhard's "Oryktognosie" (1821, 1826), following the method of Reuss of the opening century, contains a full catalogue of references to publications on each species; but it fails of half its value because the references have no connection in any way with the synonymy. In most recent works, an author who has merely adopted a name is often quoted as if the original authority. The present work is no longer open to this criticism. As now issued, the first author and first place of publication of each species, and of each name it has borne, and of the names of all its varieties, are stated in chronological order, with the dates of all publications cited; and, besides, remarks are added in the text when the subject is one of special interest. The facts and conclusions have been derived in almost all cases from the study of the original works themselves; and this Treatise has become thereby, to some extent, an account of ancient as well as modern minerals. These historical researches added a third to the labor of preparing the edition for the press, thereby delaying the publication of the work about a year. But such studies are endless, especially when they relate to past centuries, and the work, however long continued, must be incomplete. As an example: the word *schorl*, which figured largely in the mineralogy of the last century and the earlier part of the present, is traced by some writers to the Swedish, and is cited from CRONSTEDT (1758). From Dr. NAUMANN, of Leipsic, I learned of the occurrence of the word in the Magnalia Dei of BRUCKMANN (1727). Afterward I found it in ERCKER's Aula Subterranea (1595); and later in GESNER on Fossils (1565), and in the Sarepta of MATTHESIUS (1562), which contains a detailed description of it. In what earlier works the word occurs, and what was its origin, are among the questions unanswered. (See further p. 205.)

The introduction of formulas on the basis of the new system of chemistry, with the necessary explanations, constitutes another addition. The formulas, it will be observed, while in principle those of the leaders of the system, have some peculiar features, serving to give them greater compactness on the page, and make them more easy of comparison, and bringing out well the unity and simplicity of type among inorganic compounds.

In these and other ways the volume has unavoidably become enlarged. Not a page, and scarcely a paragraph, of the preceding edition remains unaltered, and full five-sixths of the volume have been printed from manuscript copy. I may here add, that, notwithstanding the impaired state of my health, this manuscript—the paragraphs on the pyrognostic characters excepted—was almost solely in the handwriting of the author, or in that of a copyist from it. Neither the consultation of original authorities, the drawing of conclusions, nor the putting of the results on paper, has been delegated to another. And being now but half way between the fifties and sixties, it is my hope that the future will afford another opportunity for similar work.

The optical qualities of minerals have been but briefly stated, and in general for those species alone which seemed to require this addition to their distinctive characters, as a full presentation of them would have added much more to the size of the volume. The best work on the subject, and one containing many original observations, is the excellent Mineralogy of DESCLOIZEAUX, the first volume of which, on the Silicates, was published in 1862. The second, unfortunately for the science, has not yet appeared. Other works in this department are BROOKE & MILLER's Mineralogy (1852); GRAILICH's Vienna edition of MILLER's Crystallography (1856), and his own Krystallographisch-optische Untersuchungen (1858).

In classification, the general system remains unaltered. It is based on a comprehensive view of the characters of minerals as species in the inorganic kingdom of nature, the preëminence being given to chemical, the next place to crystallographic, the third to the different physical characters. The author believes (after having tried the so-called natural history system of MOHS for two editions) that light from no source should be shut out where the relations of species and groups in nature are to be determined. As in the preceding edition, the method avoids almost entirely the distinction, in most cases wrong, founded on the fact of the base in oxygen ternaries or salts being in the protoxyd state, or in the sesquioxyd, or in both combined, and proceeds on the ground that the basic elements in these and the other different states are mutually replaceable in certain proportions determined by their combining power with oxygen. But while the progress of chemistry and the kindred sciences requires no modification of the general plan of the classification, but gives it new support, it has rendered many minor changes necessary, and some that are of much importance.

The historical inquiries above alluded to were prompted by a desire to place the nomenclature of mineralogy on a permanent basis. They were incident to a search after a reason for choosing one name rather than another from among the number that stand as claimants. Part of the existing diversity is due to national partiality, and much of it to indifference. It has become somewhat common for authors to select the name they like best without reference to authority, or to reject an old for a new one on no other ground than that of their preference. Increasing confusion in nomenclature has consequently attended the recent progress of the science; and in view of this fact the novel expedient has been tried of endeavoring to escape the confusion by adding one more to the number of names. The right method is manifestly that which has proved so successful in the other natural sciences, viz., the recognition, under proper restrictions, of the law of priority; and this method the author has aimed to carry out.

Moreover, it has seemed best that the science should not only have a system of nomenclature, but should also stand by it; that, accordingly, the termination *ine*, which is prominently chemical, should be left to the chemists, and that other miscellaneous endings should, as far as possible, be set aside, or be made to conform to the system. With this in view, changes have been made in accordance with the principles explained in the course of the remarks beyond on Nomenclature.

In the preparation of this volume, the author owes much to the coöperation of his friend, Prof. George J. Brush. Prof. Brush has had sole charge of the blowpipe department. The pyrognostic characters have been entirely rewritten by him; and while he has had the works of Plattner and von Kobell always at hand, he has, for much the larger part of the species, made personal trials of the reactions before writing them out; so that, although the facts stated are not generally new, they still are mostly from his own observations. His skill also in analytical chemistry, and his thorough knowledge of minerals, have enabled him to remove doubts, afford aid and advice, and furnish new facts, on various points throughout the progress of the work. Prof. Brush has also given the proofs, while the work was in the press, the benefit of his revision.

I take pleasure also in acknowledging the assistance of Prof. George F. Barker of this city, an excellent chemist in both the old and new systems, during the last six months before the book went to press; and later, that of Sydney I. Smith, assistant in the zoological department of Yale College.

The author is under obligations to many men of science for their kind response to his inquiries, and for much information in their letters; among whom he would mention, with gratitude, Dr. Carl F. Naumann of Leipzig, W. Haidinger of Vienna, Prof. von Kobell of Munich, Friedrich Hessenberg of Frankfort-on-the-Main, Dr. G. vom Rath of Bonn, Dr. G. A. Kenngott of Zurich, Dr. Hanns Bruno Geinitz of Dresden, Dr. A. Kunth of Berlin, Dr. A. Krantz of Bonn; Prof. Forchhammer of Copenhagen, Dr. A. E. Nordenskiöld of Stockholm, Prof. C. W. Blomstrand of Lund, Sweden, Mr. L. J. Igelström of Filipstad, Sweden, Prof. A. E. Arppe of Christiania, Norway; Louis Sæmann of Paris, whose letters were numerous and always valuable, and whose death, in 1866, was a misfortune to this work as well as to the sciences he cultivated; Prof. A. DesCloizeaux of Paris, A. Damour of Paris, F. Pisani of Paris, Mr. Guyerdet of Paris; David Forbes, Esq., of London, N. S. Maskelyne, Esq., of the British Museum; Dr. F. A. Genth of Philadelphia, Prof. C. U. Shepard of Amherst, Prof. J. P. Cooke of Cambridge, Mass., Prof. C. M. Warren of the Technological Institute, Boston, Prof. T. S. Hunt of Montreal, Prof. Jas. C. Booth of the U. S. Mint, Philadelphia, Prof. H. How of Windsor, Nova Scotia, Profs. Silliman, O. C. Marsh, A. E. Verrill, and W. H. Brewer, of New Haven, Ct., W. W. Jefferis, Esq., of Westchester, Pa., and Prof. A. Winchell of Ann Arbor, Michigan.

In addition, the book has received private contributions to the text of analyses and other information from P. Collier, B. S. Burton, C. S. Rodman, C. A. Goessmann, C. S. Sharples, G. F. Barker, G. C. Wheeler, and E. W. Root.

Among works consulted, the publications on chemical mineralogy of Rammelsberg of Berlin, and especially his Mineralchemie, have afforded great assistance. The very full and able Annual Reports (or Uebersichte) of Dr. Kenngott of Zurich, on the progress of mineralogy from 1844 to 1861, and those of the Giessen Jahresbericht, have been freely and constantly consulted. Much use has been made also of the mineralogical works of DesCloizeaux, Dufrénoy, Hausmann, Breithaupt, Naumann, Haidinger, von Kobell, Kokscharof, Hessenberg, Quenstedt, Brooke & Miller, Greg & Lettsom, and Shepard; also the valuable History (Geschichte) of Mineralogy of von Kobell; the classical work on the Precious Stones and Gems of the Ancients by King; and the various recent American Geological Reports. Among these Reports, the volume of the Canadian survey for the year 1863, containing extended mineralogical contributions by Prof. T. S. Hunt, deserves special mention. A full list of the works consulted in studying up the history of the species, and the later progress of the science, is to be found on pages xxxv to xlv of the Introduction.

In Crystallography, the sources of recent information have been mainly Kokscharof's Mineralogie Russlands, and his Memoirs in the Bulletin of the St. Petersburg Academy; DesCloizeaux's Mineralogie, and various Memoirs; the Mineralogische Notizen of F. Hessenberg, of which eight parts have appeared; Naumann's and Quenstedt's works on Mineralogy; the Memoirs of Zippe, von Zepharovich, Grailich, A. Schrauf, v. Lang, Zirkel, and Kenngott, in the Berichte and Denkschriften (mostly the former) of the Vienna Academy; of Dauber, G. Rose, vom Rath, Schröder, Schabus, in Poggendorff's Annalen; of Websky and vom Rath, in the Zeitschrift of the German Geological Society at Berlin; of A. E. Nordenskiöld, in the Œfversigt of the Swedish Academy; of Quintino Sella, in his Studii, and in the publications of the Turin Academy; of Miller, v. Lang, Maskelyne, and Greg, in the Philosophical Magazine; of Prof. J. P. Cooke, in the American Journal of Science. The Mineralogy of Brooke & Miller (1852) has been freely used again, as in the preparation of the preceding edition.

This volume would probably be more acceptable to some chemists if the formulas on the old system were rejected altogether. But chemistry has not advanced so far on the new road, but that most mineralogical papers are still written as if there were no new system, and a large part of chemists would understand the constitution of the species better from the old formulas than from the new. Moreover, the great majority of the persons who consult a Mineralogy would find the new formulas and new terminology quite unintelligible. It has seemed reasonable therefore that both systems should be presented. The new formulas will be more easily understood or learned from their association with the old, and thus the book may help forward the views it only partially adopts. The past history of the work evinces no aversion to change where the progress of science requires it.

This work has been posted up, as far as was possible, to the date of publication. The facts which have come to hand too late for their proper place in the volume, are inserted in a Supplement. And it is proposed to make this the first of a series of supplements to appear from time to time in the American Journal of Science.

JAMES D. DANA.

April 30, 1868.

From the Preface to the First Edition (1837).

* * * * * The classification of the mineral species, which is here adopted, is strictly a *Natural* Arrangement. The superiority of this method is exhibited in the body of the work, and in connection with the remarks on Chemical Classifications, in Appendix B. Although founded by Mohs on the external characters of minerals, it exhibits, in a considerable degree, the chemical relations of the species; and those who are accustomed to prefer a chemical arrangement will probably perceive that, in addition to such qualities as appear to recommend the chemical method it possesses other advantages not less important.

The changes which have been made in the nomenclature of minerals appear to be demanded by the state of the Science. The present names, excepting those proposed by MOHS, are utterly devoid of system, unless we may consider such the addition of the syllable *ite* to words of various languages; and even this glimmering of system has been capriciously infringed by a French mineralogist of much celebrity; —they seldom designate any quality or character peculiar to the mineral; neither do they exhibit any of the general relations of the species, by which the mind may, at a glance, discover their natural associations, and be assisted in obtaining a comprehensive view of the science. On the contrary, they are wholly independent, and often worse than unmeaning, appellatives, and are only tolerable in a very unadvanced state of the Science. As a necessary consequence of this looseness of nomenclature, most of the species are embarrassed with a large number of synonyms, a fertile source of confusion and difficulty.

As a remedy for this undesirable state of things, a system of nomenclature, constructed on the plan so advantageously pursued in Botany and Zoology, was proposed by the author in the fourth volume of the Annals of the New York Lyceum. The necessity for something of the kind is very apparent, and the author trusts that it will not be considered a needless innovation. * * * * * *

From the Preface to the Second Edition * (1844).

The natural system adopted in this Treatise has received such modifications in the present edition as were demanded by the advanced state of the Science; and the systematic nomenclature has required some corresponding changes.

Besides the natural classification, another, placing the minerals under the principal element in their composition, has been given in Part VII.; and various improvements on the usual chemical methods have been introduced, which may render it acceptable to those that prefer that mode of arrangement. * * * *

From the Preface to the Third Edition (1850).

This Treatise, in the present edition, has undergone so various and extensive alterations, that few of its original features will be recognized. The science of Mineralogy has made rapid progress in the past six years; chemistry has opened to us a better knowledge of the nature and relations of compounds; and philosophy has thrown new light on the principles of classification. To change is always seeming fickleness. But not to change with the advance of science, is worse; it is persistence in error; and, therefore, notwithstanding the former adoption of what has been called the Natural History System, and the pledge to its support given by the author in supplying it with a Latin nomenclature, the whole system, its classes, orders, genera, and Latin names, have been rejected; and even the trace of it which the synonymy might perhaps rightly bear has been discarded. The system has subserved its purpose in giving precision to the science, and displaying many of the natural groupings which chemistry was slow to recognize. But there are errors in its very foundation, which make it false to nature in its most essential points; and, in view of the character of these errors, we are willing it should be considered a relic of the past.

Yet Science is far from being ready with an acceptable substitute. Most *chemical* systems have been more artificial than the "natural" system; and doubts now hang over some of the principles of chemistry that are widest in their influence on cla fication. In view of the difficulties on either side, it was a point long question whether to venture upon a classification that might be deemed most accordant w truth among the many doubts that surround the subject; or to adopt one less str to science, that might serve the convenience of the student for easy reference, a for the study of mineralogy in its economical bearings, while, at the same time, should exhibit many natural relations, and inculcate no false affiliations or distin tions of species. The latter alternative has been adopted;—the classification offered simply as a convenient arrangement, and not an exhibition of the true affi ties of species in the highest sense of the term. Among the Silicates, however, will be perceived that the groupings in the main are natural groupings; and, throug out the work, special care has been taken to inculcate, as far as possible, the tr relations of species, both by remarks, and by an exhibition of them in tables. *

---

* This edition, failing to find a publisher in New York, was printed at the expense of the author.

From the Preface to the Fourth Edition (1854).

In the Preface to the last edition of this Treatise, the classification of mineral then adopted was announced as only a temporary expedient. The system of Mohs valuable in its day, had subserved its end; and in throwing off its shackles for th more consistent principles flowing from recent views in Chemistry, the many difficulties in the way of perfecting a new classification led the author to an arrangement which should "serve the convenience of the student without pretending to strict science."

A classification on chemical principles was however proposed in the latter part of the volume, in which the Berzelian method was coupled with crystallography in a manner calculated to display the relations of species in composition as well as form, and prominently "exhibit the various cases of isomorphism and pleomorphism among minerals." The progress of Science has afforded the means of giving greater precision and simplicity to this arrangement, until now it seems entitled to become the authorized method of a System of Mineralogy. Whether regarded from a physical or chemical point of view, the groupings appear in general to be a faithful exhibition of the true affinities of the species.

The mind uneducated in Science may revolt at seeing a metallic mineral, as galena, side by side with one of unmetallic lustre, as blende; and some systems, in accordance with this prejudice, place these species in separate orders. Like the jeweller, without as good reason, the same works have the diamond and sapphire in a common group. But it is one of the sublime lessons taught in the very portals of Chemistry, that nature rests no grand distinctions on lustre, hardness, or color, which are mere externals, and this truth should be acknowledged by the mineralogist rather than defied. Others, while recognizing the close relations of the carbonates of lime, iron, zinc, and manganese (calcite, spathic iron, smithsonite, and dialogite), or of the silicates of lime, iron, manganese (wollastonite, augite, rhodonite), are somewhat startled by finding silicate of zinc, or silicate of copper, among the silicates of the earths, or of other oxyds. But the distinction of "useful" and "useless," or of "ores" and "stones," although bearing on "economy," is not Science. * * * * * * * * *

TABLE OF CONTENTS.

Introduction.

Descriptive Mineralogy: General Subdivisions 1
I. NATIVE ELEMENTS 2
II. SULPHIDS, TELLURIDS, SELENIDS, ARSENIDS, ANTIMONIDS, BISMUTHIDS 26
1. Simple Sulphids and Tellurids of Metals of the Sulphur and Arsenic Groups 26
2. Simple Sulphids, Tellurids, Selenids, Arsenids, Antimonids, Bismuthids, Phosphids of Metals of the Gold, Iron, and Tin Groups 33
3. Sulpharsenites, Sulphantimonites, Sulphobismuthites 34
III. COMPOUNDS OF CHLORINE, BROMINE, IODINE 110
IV. FLUORINE COMPOUNDS 123
V. OXYGEN COMPOUNDS 131
I. Oxyds, or Binary Oxygen Compounds 131
I. Oxyds of Elements of Series I. 131
A. Anhydrous Oxyds 131
B. Hydrous Oxyds 167
II. Oxyds of Elements of the Arsenic and Sulphur Groups, Series II. 183
III. Oxyds of Elements of the Carbon-Silicon Group, Series II. 189
II. Ternary Oxygen Compounds 202
1. Silicates 202
A. Anhydrous Silicates 202
I. Bisilicates 207
II. Unisilicates 250
III. Subsilicates 362
B. Hydrous Silicates 393
I. General Section of Hydrous Silicates 394
II. Zeolite Section 421
III. Margarophyllite Section 447
Appendix to Hydrous Silicates 509
2. Tantalates, Columbates 512
3. Phosphates, Arsenates, Antimonates, Nitrates 526
A. Phosphates, Arsenates, Antimonates 526
I. Anhydrous 527
II. Hydrous 542
B. Nitrates 591

4. Borates 593
5. Tungstates, Molybdates, Vanadates 601
6. Sulphates, Chromates, Tellurates 613
  I. Anhydrous 613
  II. Hydrous 632
7. Carbonates 669
  I. Anhydrous 669
  II. Hydrous 704

VI. HYDROCARBON COMPOUNDS 720
Species of uncertain place in the System 761
Catalogue of American Localities 765
Supplement 793
Index 807

INTRODUCTION.

The object of this introduction is to supply such tables and information as will make the work convenient for use; and, toward this end, some explanations of an elementary character are included, with special reference to readers not familiar with chemistry and other collateral sciences.

1. General Scheme of Arrangement in the Descriptions.

In the Descriptions of Species, the characteristics are mentioned in the following order:—1, Crystalline Form and Structure; 2, Hardness, Specific Gravity, Lustre, Color, Diaphaneity, etc.; 3, Varieties, Chemical Composition; 4, Pyrognostic and other Chemical characters; 5, under the head of Observations, Geological position, Localities, Mineral associates, etc.; 6, Altered forms; 7, Artificial and Furnace products.

2. Chemistry.

1. A *barred letter* in a symbol of an element, in the table of atomic weights which follows, and also throughout the work (except in formulas after the new system, see p. xv), signifies *two* atoms of the element: *e. g.*, $\bar{\mathrm{Al}}$=2 Al or Al^2.

2. *Dots over a symbol* stand each for an atom of oxygen in the compound referred to: *e. g.*, $\dddot{\bar{\mathrm{Al}}}$=2 Al+3 O, or $\mathrm{Al}^2\,\mathrm{O}^3$; and $\dot{\mathrm{Ba}}$=BaO.

3. The *atomic weight of a compound* equals the sum of the atomic weights of its constituents: *e. g.*, for $\dddot{\bar{\mathrm{Al}}}$, the atomic weight=2 × 13·75+3 × 8=51·5; for $\dot{\mathrm{Ba}}$= 68·5+8=76·5; for $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$, the atomic weight=51·5+30=81·5.

4. The *atomic ratio* for the constituents of a compound is the ratio between the number of atoms of the same: *e. g.*, for the aluminum and oxygen in $\dddot{\bar{\mathrm{Al}}}$, it is 2 : 3; for the alumina and silica in $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$ it is 1 : 1, there being 1 of alumina to 1 of silica; for the aluminum, silicon, and oxygen in $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$, it is 2 : 1 : 5, there being in the compound 2 of aluminum, 1 of silicon, and 5 of oxygen (5 dots).

5. The *oxygen ratio* for the constituents of an oxygen compound is the ratio between the number of atoms of oxygen in the different oxygen compounds present: *e. g.*, the O. ratio for the alumina and silica in $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$ is 3 : 2, alumina containing 3 O and silica 2 O; for the magnesia and silica in $\dot{\mathrm{Mg}}\,\ddot{\mathrm{Si}}$, the O. ratio is 1 : 2.

6. The *percentage ratio* (or number of parts in 100) for the constituents of a compound is deduced from the ratio between the atomic weight of the compound and that of each constituent: *e. g.*, as 51·5 of alumina contain 24 of oxygen, so 100 will contain 46·6; or, for the percentage of aluminum, 51·5 : 27·5 : : 100 : 53·4; again, as 81·5 $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$ contain 30 of silica, hence 81·5 : 30 : : 100 : the silica in the compound, etc.; or since $\dddot{\bar{\mathrm{Al}}}\,\ddot{\mathrm{Si}}$ contain 27·5 Al+14·0 Si+40·0 O, making in all as before 81·5, hence 81·5 : 27·5 : : 100 : the p. c. of aluminum; or 81·5 : 40 : : 100 : the p. c. of oxygen; etc.

The *percentage of oxygen* in each of the oxygen compounds enumerated in th preceding table of atomic weights is stated in parentheses after the atomic weight o the compound; and the *percentage of sulphur*, in the same manner, after the atomi weight of many of the sulphids.

7. The *atomic ratio is calculated from the percentage ratio*, by dividing eac number by the atomic weight of the constituent: the percentage ratio of Al and (in alumina being 53·4 : 46·6, 53·4 ÷ 13·75 gives 3·93, and 46·9 ÷ 8 = 5·85; whenc the ratio 3·93 : 5·85, which, by dividing the larger by the smaller, is found to equa 1 : 1·5 or 2 : 3, which is the atomic ratio of the aluminum to the oxygen.

For the compound $\dddot{\bar{A}}l\,\ddot{S}i$, the percentage of silica and alumina is 36·8, 63·2 whence, dividing the former by 30 (at. w. of silica), and the latter by 51·5 (at. w. of alumina), the ratio obtained is 1 : 1, the compound consisting of 1 of each alumin and silica; or taking the percentage for the silicon, aluminum, and oxygen in the same, and dividing them, respectively, by 14, 13·75, 8, the ratio deduced would be 1 : 2 : 5.

8. The ratio of alumina and silica in a compound may also be obtained by comparing the amounts of oxygen in the percentages of the constituents. Take, *e. g.*, a silicate of alumina consisting of $\ddot{S}i$ 36·8, $\dddot{\bar{A}}l$ 63·2 = 100. If 100 of silica contain 53·33 of oxygen (see table) then 36·8 will contain 36·8 × ·5333 or 19·625 (since 100 : 36·8 : : 53·33 : the required percentage); so if 100 of alumina contain 46·6 of oxygen, 63·2 will contain 46·6 × ·632 or 29·45; now 19·625 : 29·45 (the ratio obtained) = 2 : 3; and since silica contains 2 of oxygen and alumina 3, it follows from the result of the calculation that the compound contains 1 of silica to 1 of alumina, or has the formula $\dddot{\bar{A}}l\,\ddot{S}i$. This is the usual method of calculating the ratio of the constituents in the case of oxyds. It involves multiplications of the percentage of each of the constituents by the percentage of oxygen for that constituent; and in order to facilitate these multiplications a table is given below the table of atomic weights, containing multiples of these oxygen percentages for each of the digits 1 to 9.

9. The letter R is used as a general symbol for any element; $\dot{R}$, for protoxyds in general; $\dddot{\bar{R}}$, for sesquioxyds in general.

10. In the formula $3\,\dot{C}a^2\,\ddot{S}i+\dddot{\bar{A}}l^2\,\ddot{S}i^3$, the prefix 3 applies to the whole $\dot{C}a^2\,\ddot{S}i$ (or, in general, to all before the first comma, or first + or —); but the small ² only to $\dot{C}a$, it signifying 2 $\dot{C}a$; and, in the second part, the small ² signifies that there are 2 $\dddot{\bar{A}}l$, and the small ³, 3 $\ddot{S}i$. The oxygen ratio for the $\dot{C}a$ and $\ddot{S}i$ in the first part is 1 : 1, there being 2 $\dot{C}a$ to 1 $\ddot{S}i$, 2 $\dot{C}a$ as well as 1 $\ddot{S}i$ containing 2 O; and in the second part it is 1 : 1, there being 2 $\dddot{\bar{A}}l$ to 3 $\ddot{S}i$. The oxygen ratio for the whole $\dot{C}a$, $\dddot{\bar{A}}l$, $\ddot{S}i$ in the formula is 6 : 6 : 12 = 1 : 1 : 2; and for the $\dot{C}a+\dddot{\bar{A}}l$, $\ddot{S}i$ it is 1 + 1 : 2 or 1 : 1.

In the formula $(\frac{1}{2}\,\dot{C}a^3+\frac{1}{2}\,\dddot{\bar{A}}l)^2\,\ddot{S}i^3$, the index ² signifies 2 of all within the parenthesis. The oxygen ratio of the part in the parenthesis is 1 : 1, there being $\frac{1}{2}\,\dot{C}a^3$ to $\frac{1}{2}\,\dddot{\bar{A}}l$; the O. ratio for $\dot{C}a$, $\dddot{\bar{A}}l$, $\ddot{S}i$, in the formula, is 1 : 1 : 2; and for $\dot{C}a+\dddot{\bar{A}}l$, $\ddot{S}i$, it is 1 : 1. Thus the two formulas here explained express identically the same constitution.

There are many compounds allied to the above, for example: $(\frac{1}{2}\,\dot{M}g^3+\frac{1}{2}\,\dddot{\bar{A}}l)^2\,\ddot{S}i^3$, $(\frac{1}{2}\,\dot{F}e^3+\frac{1}{2}\,\dddot{\bar{A}}l)^2\,\ddot{S}i^3$, $(\frac{1}{2}\,\dot{M}g^3+\frac{1}{2}\,\dddot{\bar{F}}e)^2\,\ddot{S}i^3$, etc. The symbol R is used, in the manner above explained, in writing a general formula for the group containing these and other related compounds; as $(\frac{1}{2}\,\dot{R}^3+\frac{1}{2}\,\dddot{\bar{R}})^2\,\ddot{S}i^3$. So $\dot{R}\,\ddot{C}$ is a general symbol for any carbonate of a protoxyd—whether of lime, magnesia, oxyd of zinc, or any other base.

11. In the preceding table, and throughout this volume, except under the sulphur compounds, As, Sb, Bi, Ni, P, in formulas under the old system, would be more correctly written As_2, Sb_2, Bi_2, Ni_2, P_2, or $\bar{A}s$, $\bar{S}b$, $\bar{B}i$, $\bar{N}i$, $\bar{P}$. The atomic weights of these elements in the table are double the value which is often given them in the old system.

12. *Binary compounds* are those consisting of elements of two kinds, those of one kind negative to the other: *e. g.*, magnesia, MgO, consisting of magnesium and oxygen; water, HO; silicic acid, or silica, SiO^2; pyrite, FeS^2.

Ternary compounds (called also *salts* and *double binaries*) consist of elements of three kinds, (1) *basic*, (2) *acidic*, (3) *acidific*. Thus a silicate of lime and magnesia (or calcium and magnesium) contains (1) calcium and magnesium, (2) silicon, (3) oxygen; sulphate of lead contains (1) lead, (2) sulphur, (3) oxygen; the sulphantimonite, jamesonite, contains (1) lead and iron, (2) antimony, (3) sulphur.

13. *Polymeres* are distinct substances that are atomically multiples of a common type. Thus the compounds $2\,\Theta H^2$, $3\,\Theta H^2$, $4\,\Theta H^2$ (generally written $\Theta^2 H^4$, $\Theta^3 H^6$, $\Theta^4 H^8$), are polymeres of ΘH^2.

14. The following principle is of great importance in connection with the chemical constitution of inorganic compounds, and although explained briefly elsewhere (pp. 1–3 and 202), deserves to be formally stated in this place:

The replacing power of the elements is in proportion to their combining power, this combining power being reckoned in number of atoms of oxygen (or sulphur, or the acidific element, whatever it may be).

The line A, below, contains the formulas of the different kinds of oxyds; B, the same, divided each by its number of atoms of oxygen (that is, severally, for the successive members, by 1, 3, 2, 5, 3, 7, 4), by which division they are reduced to the protoxyd form; C, the basic elements without the oxygen:

A.	RO	R^2O^3	RO^2	R^2O^5	RO^3	R^2O^7	RO^4
B.	RO	$R^{\frac{2}{3}}O$	$R^{\frac{1}{2}}O$	$R^{\frac{2}{5}}O$	$R^{\frac{1}{3}}O$	$R^{\frac{2}{7}}O$	$R^{\frac{1}{4}}O$
C.	R	$R^{\frac{2}{3}}$	$R^{\frac{1}{2}}$	$R^{\frac{2}{5}}$	$R^{\frac{1}{3}}$	$R^{\frac{2}{7}}$	$R^{\frac{1}{4}}$

According to the above law, the R, $R^{\frac{2}{3}}$, $R^{\frac{1}{2}}$, etc., in the last line are mutually replaceable, 1 for 1, although in atomic weight there is a variation from 1 to $\frac{1}{4}$. They represent different states in which elements may exist, and have, to a certain extent, independent element-like relations. In some cases, as in iron, four of these states are represented in a single element, the compounds (1) FeO, FeS, (2) Fe^2O^3, (3) FeS^2, (4) FeO^3, containing this metal in the four states Fe, $Fe^{\frac{2}{3}}$, $Fe^{\frac{1}{2}}$, $Fe^{\frac{1}{3}}$.

These different states of elements are best designated in the symbol by the letters of the Greek alphabet, as thus the confusion arising from the conflicting numbers for atomic weights and combining relations are avoided. The above lines A, B, C, thus written, will become:

A.	αRO	$3\beta RO$	$2\gamma RO$	$5\delta RO$	$3\epsilon RO$	$7\zeta RO$	$4\eta RO$
B.	αRO	βRO	γRO	δRO	ϵRO	ζRO	ηRO
C.	αR	βR	γR	δR	ϵR	ζR	ηR

In each table the line B is like C, except in the addition of O; and the line A is equivalent to B multiplied for the successive members by the number of atoms of oxygen in the oxyds, that is, severally, by 1, 3, 2, 5, 3, 7, 4. Examples of the use of these symbols are unnecessary here, as they occur on the pages referred to, and throughout the volume.

15. In the statements of analyses throughout this volume, the use of brackets enclosing figures implies that the substance referred to was determined by the loss.

New System of Chemistry. In the new system of Chemistry many of the elements have their atomic weights of double the value given in the preceding table, and their symbols are accordingly written with a barred letter, as follows:

Fluorine, F	19	Potassium, K	39·1		

The elements in the preceding table whose atomic weights are not doubled (c which have not barred letters in the symbols), are hydrogen; gold, silver; the alka metals, potassium, etc.; the arsenic group, arsenic, antimony, bismuth, nitroge phosphorus, with boron; the chlorine group, chlorine, bromine, iodine.

17. In the combinations between elements of the former series occur, hydroge being taken as the unit, the ratios 1 : 1, 1 : 3, 1 : 5; and, with reference to the *od* numbers 1, 3, 5, these elements are called *perissads.* While in the combinatio between elements of the latter series occur, taking the same unit, the ratios 2 : 2 2 : 4, 2 : 6; and these, in view of the *even* numbers, are called *artiads.* The word περισσός and ἄρτιος were the words for *odd* and *even* numbers in ancient arithmetic.

18. As oxygen is one of the doubled elements, a protoxyd of a perissad must contain 2 of the latter; and water, accordingly, has the formula $H_2\Theta$, potash $K_2\Theta$, sod $Na_2\Theta$, etc. But the protoxyds of elements of the other series have simply the symbols M̶g Θ for magnesia, Θa Θ for lime, etc.

19. In the formulas of the salts, or *ternaries*, instead of dividing the oxygen between the acidific and basic elements (thus making the acid and base in the compound distinct, as in the old system), the symbol of each of the elements is placed separately. Thus, $\dot{\text{Mg}}^2\ddot{\text{Si}}$ becomes $\text{Si M̶g}_2\,\Theta_4$; or, in the method of writing adopted in this work, $\text{Si}|\Theta_4|\text{M̶g}_2$.

20. It is held that in some classes of compounds only part of the oxygen serve to unite the acidic element (Si) to the basic. For example, for $\dot{\text{Mg}}\ddot{\text{Si}}$ the formula is $\text{Si}\,\Theta|\Theta_2|\text{M̶g}$, only two of the three of oxygen being regarded as *uniting* oxygen. To explain:

20. As silicon combines with 2Θ, and 2Θ are equivalent to 4 H; and magnesia, o any protoxyd, with 1Θ, which equals 2 H; the combining character of silicon is repre

sented by , and that of magnesium by H—Mg—H, silicon having *four* bonds of attraction (being therefore a *tetrad*), and magnesium *two* (it being a *dyad*). Combining the two makes  Substituting Θ for 2 H in the diagram, it becomes ; in which only *two* Θ unite the Mg and Si, *one* Θ being combined alone with the Si. Hence the form of the above formula, $\mathrm{Si}\,\Theta|\Theta_2|\mathrm{Mg}$.

If the silica is combined with two of magnesia (using the language of the old system), the diagram becomes ; and, substituting oxygen as before, . Here all the oxygen is *uniting* oxygen, and the formula is accordingly $\mathrm{Si}|\Theta_4|\mathrm{Mg}_2$.

21. The number of atoms of *uniting* oxygen is *equal to the number of bonds of attraction in the basic or acidic element, according as the former or latter has the smaller number.* If, in the case of a compound containing *one* of silica, the base is *one* of a protoxyd (on the old system), there are two bonds of attraction in the protoxyd, and therefore Θ_2 is the uniting oxygen, one Θ remaining with the Si. If the base is two of a protoxyd there are four bonds of attraction in the basic element (as well as the acidic), and the uniting oxygen is Θ_4. If the base is three of a protoxyd, or one of a sesquioxyd, the silica then has the *smaller* number of bonds of attraction, namely but *four*, and the uniting oxygen will be Θ_4, the rest being united with the basic element and not the silicon; and it cannot exceed this, however much the amount of base be increased, *it being determined by the greatest number of bonds of attraction common to the two, the basic and acidic elements.* With two of silica the bonds of attraction will be *eight*, and so on.

22. The rule above given may be also stated in terms of the oxygen of the base and acid in the old system: the number of atoms of uniting oxygen is double the number of atoms of oxygen of the base, unless the number of atoms of the base is greater than that of the acid: and in this latter case it is double the number of atoms of oxygen in the acid. In the former case the formula should have the non-uniting Θ after the symbol of the acidic element (after Si in a silicate, S in a sulphate, etc.); in the latter, it is written after that of the basic element. In the former, the acidic element makes the *left* part of the formula; in the latter the formula is turned about, and it makes the *right* part. See for examples of the latter, p. 362.

23. For the *sulphur*, *selenium*, and *tellurium compounds* (that is, sulphids, etc.), the formulas are like those of the oxygen compounds, except that S, Se, or Te is substituted for Θ. So also for ternary fluorids. In some oxygen compounds (topaz, etc.) Θ is replaced in part by F_2 (or, as the symbol for fluorine may then be written, F); and in a few others, by Cl_2.

24. In the new system the expressions on p. xv, βR, γR, δR, εR, etc., become βR, γR, δR, εR; or, in the case of perissads, $\beta\mathrm{R}_2$, $\gamma\mathrm{R}_2$, etc. As, $\dddot{\mathrm{As}}$, and $\dddot{\mathrm{B}}$ of the old system become $\mathrm{As}_2\,\Theta_3$, and $\mathrm{B}_2\,\Theta_3$ in the new, and As and B are not monads, these formulas are equivalent under the new system to $3\,\beta\mathrm{As}\,\Theta$, $3\,\beta\mathrm{B}\,\Theta$.

25. The classification in this work is based on the following classification of the elements, a partial exhibition of which is presented beyond on pages 1–3, and 202

Classification of the Elements.

Series I.	**Series II.**	**Series III.**
A. *Perissads.*	A. *Perissads.*	A. *Perissads.*
Potassium, Sodium, Cæsium, Rubidium, Lithium, Thallium, Hydrogen, Silver, Gold.	Nitrogen, Phosphorus, Arsenic, Antimony, Bismuth, Columbium, Tantalum, in the δR state. Boron ?	Chlorine, Bromine, Iodine.
B. *Artiads.*	B. *Artiads.*	B. *Perissad* (or *Artiad*).
1. IRON-ALUMINUM GROUP.	1. SULPHUR GROUP.	Fluorine.
a. IRON SUB-GROUP.—Platinum, etc., Copper, Lead, etc., Iron, Cobalt, Zinc, Cadmium, Nickel, Manganese, Chromium, Tungsten, etc., Cerium, Yttrium, etc., Magnesium, Calcium, Strontium, Barium; also H_2, K_2, Na_2, etc.		C. *Artiad.*
b. ALUMINUM SUB-GROUP.—Aluminum (βAl): also βFe, βMn, βƟr, βB, etc.	Sulphur (ϵS), Selenium, Tellurium, Molybdenum; also ϵFe, ϵƟr, ϵMn, ϵV, ϵW.	Oxygen.
2. TIN GROUP.	2. CARBON-SILICON GROUP.	
Tin, Titanium, Zirconium, Thorium; also γH_2, γFe, γMn, γƟo, γPb, γƟu, etc.	Carbon, Silicon; also γS, γSe, γTe, etc.	

This classification assumes that the metal iron, for example, when in the deutoxyd state, is of the same group with titanium or tin in the deutoxyd state; that chromium, molybdenum, etc., in the tritoxyd state, belong to the same group with sulphur, selenium, boron, etc., in the tritoxyd state; and further, that while silicon and the elements of the tin group are unquestionably allied, the latter are basic to the former in all combinations of the two.

In the earlier part of the volume, the formulas on the new system are not given. Examples of the several kinds under each of the subdivisions are here presented, and from them the student will easily supply those here omitted.

26. *Sulphids, Tellurids, Selenids, Arsenids, Antimonids, Bismuthids.* The following are the formulas of species from the lists on pages 26, 34, 84, 85, each being indicated by its number instead of its name. The atomic weights of the sulphur and arsenic groups in the new system are *relatively the same* with those that are used in the sections beyond on the Sulphids, those of the arsenic series employed in these sections being half less than are given in the table on pages xii, xiii.

1.	26. $As_2 S_2$	27. $As_2 S_3$	34. $Mo S_2$
2, I.	35. $Ag_4 Sb$	36. $Ag_{12} Bi$	37. $Ɵu_3 As_2$
2, II.	40. $Ag_2 S$	46. (Pb, Ɵu) Se	56. Zn S
	41. (Ag_2, Pb) S	47. (Pb, Hg) Se	58. $Ag_2 Te$
	44. Pb S	48. Pb Te	61. Ɵu S
	45. Pb Se	49. (Ɵu, Fe) S	62. (Ɵu, Ag_2) S

1. III. 75. $\not{\mathrm{F}}\mathrm{e\,S_2}$ or $\gamma\not{\mathrm{F}}\mathrm{e_2\,S_3}$
81. $2\,\Theta\mathrm{o\,S} + \Theta\mathrm{o\,S_2}$, or $(\Theta\mathrm{o}, \gamma\,\mathrm{Co})_2\,\mathrm{S_3}$
83. $(\Theta\mathrm{o}, \not{\mathrm{F}}\mathrm{e}, \not{\mathrm{N}}\mathrm{i})\,\mathrm{As_2}$, or $\gamma\not{\mathrm{R}}_2\,\mathrm{As_3}$
85. $\Theta\mathrm{o\,(S, As)_2}$, or $\gamma\Theta\mathrm{o_2\,(S, As)_3}$
86. $\not{\mathrm{N}}\mathrm{i\,(S, As)_2}$, or $\gamma\not{\mathrm{N}}\mathrm{i_2\,(S, As)_3}$
94. $\not{\mathrm{F}}\mathrm{e\,(S, As)_2}$, or $\gamma\not{\mathrm{F}}\mathrm{e_2\,(S, As)_3}$
98. $\mathrm{(Ag_2\,Au_2)}\,\not{\mathrm{T}}\mathrm{e_3}$
100. $\Theta\mathrm{u\,S}$

3 101. $\mathrm{Sb_2\,S_2|S_2|}\Theta\mathrm{u}$
102. $\mathrm{Bi_2\,S_2|S_2|}\Theta\mathrm{u}$
104. $\mathrm{Sb_2\,S_2|S_2|}\not{\mathrm{F}}\mathrm{e}$
105. $\mathrm{As_2\,S_2|S_2|}\not{\mathrm{P}}\mathrm{b}$
108. $\mathrm{Sb_2\,S_2|S_2|Ag_2}$
110. $\mathrm{As_2\,S_{\frac{3}{2}}|S_2|}\Theta\mathrm{u_{\frac{3}{2}}}$
111. $\mathrm{Sb_2\,S|S_4|(}\not{\mathrm{P}}\mathrm{b, Ag_2)_2}$
113. $\mathrm{As_2\,S|S_4|}\not{\mathrm{P}}\mathrm{b_2}$
117. $\mathrm{Sb_2|S_6|(Ag_2)_3}$
118. $\mathrm{As_2|S_6|(Ag_2)_3}$
119. $\mathrm{Sb_2|S_6|(}\Theta\mathrm{u}, \not{\mathrm{P}}\mathrm{b)_3}$
121. $\mathrm{Bi_2|S_6|}\Theta\mathrm{u_3}$
122. $\mathrm{Sb_2|S_6|}\not{\mathrm{P}}\mathrm{b_3}$
123. $\mathrm{(Bi_2, Sb)|S_6|}\not{\mathrm{P}}\mathrm{b_3}$
125. $(\Theta\mathrm{u}$, etc., $\mathrm{S|S_6|(Sb_2, As_2)}$
127. $(\Theta\mathrm{u}, \not{\mathrm{F}}\mathrm{e})_4\,\mathrm{S|S_6|As_2}$
128. $(\not{\mathrm{P}}\mathrm{b_4\,S|S_6|Sb_2}$
129. $\not{\mathrm{P}}\mathrm{b_5\,S_2|S_6|(Sb_2, As_2)}$
130. $\mathrm{(Ag_2)_5\,S_2|S_6|Sb_2}$
131. $(\mathrm{Ag_2}, \Theta\mathrm{u})_{10}\,\mathrm{S_7|S_6|(Sb_2 + As_2)}$
132. $\mathrm{As_2\,S_2|S_6|}\Theta\mathrm{u}$

27. *Chlorids, Bromids, Iodids.* For the Chlorids, Bromids, Iodids, p. 110, the following are examples of the new formulas:

136. $\not{\mathrm{H}}\mathrm{g_2\,Cl_2}$
137. $\mathrm{K\,Cl}$
138. $\mathrm{Na\,Cl}$
139. $\mathrm{N\,H_4\,Cl}$
140. $\mathrm{Ag\,Cl}$
142. $\mathrm{Ag\,Br}$
143. $\mathrm{Ag\,I}$
144. $\not{\mathrm{H}}\mathrm{g_2\,I_2}$
145. $\not{\mathrm{P}}\mathrm{b\,Cl_2}$
146. $\not{\mathrm{F}}\mathrm{e_2\,Cl_6}$
147. $(\mathrm{K_2}, \not{\mathrm{M}}\mathrm{g})\,\mathrm{Cl_2} + 4\,\mathrm{aq}$
148. $(\Theta\mathrm{a}, \not{\mathrm{M}}\mathrm{g})\,\mathrm{Cl_2} + 4\,\mathrm{aq}$
150. $\not{\mathrm{P}}\mathrm{b}\,(\tfrac{1}{2}\,\mathrm{Cl_2} + \tfrac{1}{2}\,\Theta)$
151. $\not{\mathrm{P}}\mathrm{b}\,(\tfrac{1}{3}\,\mathrm{Cl_2} + \tfrac{2}{3}\,\Theta)$

28. *Fluorids.* Under the Fluorids, if fluorine is taken as a perissad, among the formulas of p. 123, $\mathrm{Ca\,F}$=in the new system, $\Theta\mathrm{a\,F_2}$; $\mathrm{Ce\,F} = \Theta\mathrm{e\,F_2}$; $3\,\mathrm{Na\,F} + \mathrm{Al^2\,F^3} = \mathrm{Na_6}\,\not{\mathrm{A}}\mathrm{l_2\,F_{12}}$; $\mathrm{(Ca, Na)_2\,F} + \mathrm{Al^2\,F^3} = (\Theta\mathrm{a}, \mathrm{Na_2})_2\,\not{\mathrm{A}}\mathrm{l_2\,F_8}$.

29. *Oxyds.* A. For the *Anhydrous Oxyds*, pp. 131, 132, examples of the formulas are:

1. 173. $\not{\mathrm{M}}\mathrm{g}\,\Theta$
175. $\mathrm{H_2}\,\Theta$
176. $\not{\mathrm{Z}}\mathrm{n}\,\Theta$

2. 179. $\not{\mathrm{A}}\mathrm{l_2}\,\Theta_3$, or $\beta\not{\mathrm{A}}\mathrm{l_2}\,\Theta_3$
180. $\not{\mathrm{F}}\mathrm{e_2}\,\Theta_3$, or $\beta\not{\mathrm{F}}\mathrm{e_2}\,\Theta_3$
181. $(\not{\mathrm{F}}\mathrm{e}, \beta\not{\mathrm{F}}\mathrm{e}, \gamma\not{\mathrm{T}}\mathrm{i})_3\,\Theta_3$
182. $(\Theta\mathrm{a}, \gamma\not{\mathrm{T}}\mathrm{i})_3\,\Theta_3$

3. 1. 183. $(\tfrac{1}{4}\not{\mathrm{M}}\mathrm{g} + \tfrac{3}{4}(\beta\not{\mathrm{A}}\mathrm{l}, \beta\not{\mathrm{F}}\mathrm{e}))_4\,\Theta_4$.
184. $(\tfrac{1}{4}\not{\mathrm{F}}\mathrm{e} + \tfrac{3}{4}\beta\not{\mathrm{A}}\mathrm{l})_4\,\Theta_4$
186. $(\tfrac{1}{4}\not{\mathrm{F}}\mathrm{e} + \tfrac{3}{4}\beta\not{\mathrm{F}}\mathrm{e})_4\,\Theta_4$
187. $(\tfrac{1}{4}\not{\mathrm{M}}\mathrm{g} + \tfrac{3}{4}\beta\not{\mathrm{F}}\mathrm{e})_4\,\Theta_4$
188. $(\tfrac{1}{4}(\not{\mathrm{Z}}\mathrm{n}, \not{\mathrm{F}}\mathrm{e}, \not{\mathrm{M}}\mathrm{n}) + \tfrac{3}{4}(\beta\not{\mathrm{F}}\mathrm{e}, \beta\not{\mathrm{M}}\mathrm{n}))_4\,\Theta_4$
189. $(\tfrac{1}{4}(\not{\mathrm{F}}\mathrm{e}, \not{\mathrm{M}}\mathrm{g}, \Theta\mathrm{r}) + \tfrac{3}{4}\beta\not{\mathrm{R}})_4\,\Theta_4$

3, 2 191. $(\tfrac{1}{4}\not{\mathrm{B}}\mathrm{e} + \tfrac{3}{4}\beta\not{\mathrm{A}}\mathrm{l})_4\,\Theta_4$

4. 192. $\mathrm{Sn}\,\Theta_2$, or $\gamma\mathrm{Sn_2}\,\Theta_3$
193. $\not{\mathrm{T}}\mathrm{i}\,\Theta_2$, or $\gamma\not{\mathrm{T}}\mathrm{i_2}\,\Theta_3$
195. $(\tfrac{1}{2}\not{\mathrm{M}}\mathrm{n} + \tfrac{1}{2}\gamma\not{\mathrm{M}}\mathrm{n})_2\,\Theta_2$
197. $(\tfrac{1}{2}\not{\mathrm{P}}\mathrm{b} + \tfrac{1}{2}\gamma\not{\mathrm{P}}\mathrm{b})_2\,\Theta_2$

The general formula for the Spinel group is $(\tfrac{1}{4}\not{\mathrm{R}} + \tfrac{3}{4}\beta\not{\mathrm{R}})_4\,\Theta_4$.

The spinel formula written, as ordinarily done under the new system, without the Greek symbol, would be $(\not{\mathrm{R}} + \not{\mathrm{R}}_2)\,\Theta_4$. But this formula contains the fiction of $2\,\not{\mathrm{R}}$ in $\not{\mathrm{R}}_2\Theta_3$; when, in fact, while there are $2\,\not{\mathrm{R}}$ in atomic weight, there are actually $3\,\not{\mathrm{R}}$ in replacing power, as already explained (p. xv). Some additional sign is therefore required to make the formula tell the truth, and this is afforded either by adding other numbers to the barred letters, or by the use of the Greek letters as here adopted.

30. B. For the *Hydrous Oxyds*, p. 167, the formulas become, if the species are regarded as only oxyds:

202. $(\tfrac{1}{7}\,\mathrm{H_2} + \tfrac{6}{7}\,\beta\not{\mathrm{F}}\mathrm{e})_3\,\Theta_3$
203. $(\tfrac{1}{4}\,\mathrm{H_2} + \tfrac{3}{4}\,\beta\not{\mathrm{A}}\mathrm{l})_3\,\Theta_3$
204. $(\tfrac{1}{4}\,\mathrm{H_2} + \tfrac{3}{4}\,\beta\not{\mathrm{F}}\mathrm{e})_3\,\Theta_3$
205. $(\tfrac{1}{4}\,\mathrm{H_2} + \tfrac{3}{4}\,\beta\not{\mathrm{M}}\mathrm{n})_3\,\Theta_3$
206. $(\tfrac{1}{3}\,\mathrm{H_2} + \tfrac{2}{3}\,\beta\not{\mathrm{F}}\mathrm{e})_3\,\Theta_3$
207. $(\tfrac{2}{5}\,\mathrm{H_2} + \tfrac{3}{5}\,\beta\not{\mathrm{F}}\mathrm{e})_3\,\Theta_3$

[illegible] [illegible] [illegible]

[illegible] [illegible] O_3-3 aq

[illegible] [illegible] [illegible]

[illegible] O_3-2 aq

But if hydrates or salts, as generally admitted, the formulas are:

[illegible] [illegible] [illegible]

31. C. For the Oxyds of Elements of the Arsenic Group, etc., p. 185, the formulas are:

[illegible] As_2O_3 [illegible] [illegible] [illegible] [illegible] or [illegible]

[illegible] Sb_2O_3 [illegible] [illegible] [illegible] [illegible]

The hydrated species are properly ternaries; but there is still some doubt over their composition.

3. PHYSICAL AND BLOWPIPE CHARACTERS.

1. In the descriptions of the physical characters of minerals, H. stands for hardness, and G. for specific gravity.

2. The scale of hardness is as follows, crystallized varieties of the minerals mentioned being meant: 1. TALC; 2. GYPSUM; 3. CALCITE; 4. FLUORITE; 5. APATITE; 6. ORTHOCLASE; 7. QUARTZ; 8. TOPAZ; 9. CORUNDUM; 10. DIAMOND.

3. In crystallized minerals of the isometric system, the physical characters are the same in the directions of the three axes, and in the directions of lines situated symmetrically with reference to these axes. In the Tetragonal and Hexagonal systems, these characters in a vertical direction differ from those in a horizontal or transverse. The optical axis has the direction of the vertical axis.

4. In crystals of the remaining systems there are two axes of polarization. A line bisecting the acute, or the obtuse, angle between these optical axes is called a *bisectrix*; that bisecting the acute angle is the *acute bisectrix*, or *the bisectrix*, as the term is employed in the descriptions beyond; that bisecting the obtuse angle, and which is at right angles to the acute, is the *obtuse* or *supplementary bisectrix*.

5. In the orthorhombic system, the two bisectrices are parallel to the crystallographic axes; and, consequently, the plane of the optical axes (the optic-axial plane) is parallel to one of the diametral sections of the crystal, and is at right angles to the other two.

By a *diametral plane* or section, as here used, is meant a plane passing through any two of the crystallographic axes; that is, one through each *a* and *b*, *a* and *c*, or *b* and *c*.

6. In mineral species, the position of the bisectrix is constant, or nearly so, while the optic-axial angle often varies widely. The angles mentioned in the descriptions are those taken in the air, unless it is otherwise stated.

7. Under Blowpipe characters, B.B. stands for *before the blowpipe*; O.F. for *oxidizing flame*; R.F. for *reducing flame*. A *closed tube* is a small glass tube closed at one end.

The following is the scale of fusibility adopted (that of von Kobell): 1, Gray Antimony; 2, Natrolite; 3, Almandine (var. of garnet); 4, Green Actinolite 5, Orthoclase; 6, Bronzite.

4. Crystallography.

I. The systems of crystallization are as follows:
1. *Having the axes equal.* The Isometric system.
2. *Having only the lateral axes equal.* The Tetragonal and Hexagonal.
3. *Having the axes unequal.* The Orthorhombic, Monoclinic, and Triclinic.

The names Monometric, Dimetric, and Trimetric, used in former editions of this work, have been set aside for the above for two reasons: (1) the fact that the names want precision, the hexagonal system being as much *dimetric* as the tetragonal, and the monoclinic and triclinic as much *trimetric* as the orthorhombic; (2) the desire to promote uniformity in the language of science. The names employed appear to be the best that have been proposed, and those most generally used; and hence those that have the best claim for universal adoption.

A. *Isometric System.* 2. Some of the simpler isometric forms are represented in figures 1 to 50. Fig. 1, a cube (with three equal axes); 2, an octahedron (or regular octahedron); 3, a dodecahedron (or rhombic dodecahedron); 4, 5, combination of cube and dodecahedron; 6, 7, cubo-octahedron; 8, combination of octahedron and dodecahedron (by noting the lettering, like planes being lettered alike throughout, the several combinations are easily read off); 10, a trapezohedron (24-faced solid); 15, id., another variety; 31, a tetrahedron; 47, 48, the pentagonal dodecahedron in different positions.

3. The following are some of the angles among isometric forms; adjacent planes are to be understood, unless it is stated otherwise:

O ∧ *O*=90°, f. 1.
O ∧ 1=125 16′, f. 6, 7.
O ∧ *i*=135, f. 4, 5.
O ∧ *i*-$\frac{20}{19}$=
O ∧ *i*-$\frac{4}{3}$=143 8
O ∧ *i*-$\frac{6}{5}$=140 11
O ∧ *i*-$\frac{5}{4}$=141 20
O ∧ *i*-$\frac{3}{2}$=146 19
O ∧ *i*-2=153 26, f. 16, 17.
O ∧ *i*-$\frac{7}{3}$=156 48
O ∧ *i*-$\frac{5}{2}$=158 12
O ∧ *i*-3=161 34
O ∧ *i*-4=165 58
O ∧ *i*-5=168 41
O ∧ *i*-40=178 34
O ∧ $\frac{4}{3}$-$\frac{4}{3}$=133 19
O ∧ $\frac{3}{2}$-$\frac{3}{2}$=136 45
O ∧ 2-2=144 44, f. 9, 10.
O ∧ $\frac{5}{2}$-$\frac{5}{2}$=150 30

The angles A, B, C, above, are those over the edges so lettered in the figure referred to, or over the corresponding edges in related forms.

4. Figures 29 to 49 represent *hemihedral* forms, or those having for some or all the

planes *half* the number which complete symmetry requires. In f. 29 the plane 1 occurs on only *half* the 8 solid angles, and 31, the tetrahedron, results from the extension of these planes; and so for the rest. Figures 29 to 40 are of *inclined* hemihedrons; and 41–49 of *parallel* hemihedrons. Some of the angles are as follows; many are the same as for the preceding forms.

In the forms *i*-$\frac{3}{2}$, *i*-2 (f. 47), *i*-3, *i*-4, A is the angle at the longer edge, and C that at either of the others.

50A

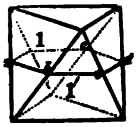

Fig. 50 represents a common twin or compound crystal in the isometric system; and 50A illustrates that it corresponds to an octahedron cut across the middle parallel to an octahedral face, with one half revolved 60 or 180 degrees.

B. *Tetragonal System.* (Also called Quadratic, Pyramidal, Monodimetric, Dimetric, Zwei-und-einaxige.) 5. In the Tetragonal system the *lateral* axes (b) are equal, being the diameters or diagonals of a square, while the *vertical* (a) is either longer or shorter than the lateral.

6. Owing to the *square* form, the planes of a kind are in *fours* or *eights*. The like planes on the four solid angles make a 4-sided pyramid, and those of the two extremities combined a square octahedron. For any species one such octahedron may be assumed to have the vertical axis 1a; and then the other octahedral planes on the same angles, with shorter or longer vertical axes, have the vertical axis a multiple or submultiple of a; as $\frac{1}{2}a$, $\frac{1}{3}a$, etc., 2a, $\frac{3}{2}a$, 3a, etc.; and the planes of such octahedrons are accordingly lettered 1, $\frac{1}{2}$, $\frac{1}{3}$, 2, $\frac{3}{2}$, 3, etc.

7. So again like planes on the four edges of each base make an octahedron, but of an intermediate series, called the diametric, the planes being parallel to a lateral axis or diagonal. The vertical axis varies by simple ratios, as in the other series; but in the lettering, as the planes are parallel to a lateral axis (and would therefore meet it only at an infinite distance), this parallelism is expressed by adding the letter i, initial of infinity. Thus $\frac{1}{2}$-i, 1-i, 2-i, 3-i, etc.

8. With the lengthening of the octahedron in each series, the numeral becomes arger and larger, until the octahedron is merged in a *vertical square prism*, its planes parallel to the vertical axis. This parallelism, expressed by the letter i again, as just explained, gives for the lettering of the square prism of the first or fundamental series, i or I; and for that of the second or diametric, i-i. The figures on pages 277, 273, are examples of these forms, and also of the double 8-sided pyramids and 8-sided prisms which occur in this system.

9. The angles between the planes on the vertical edges and I, or i-i, are the same as those having similar symbols in the isometric system, noting only this difference in the lettering, that O in the cube is i-i in the square prism: thus $O \wedge i$-2 in the cube or other isometric form is the same with i-$i \wedge i$-2 in the tetragonal system; and so on.

10. The length of the vertical axis a is calculated from the supplement (S) of the angle $O \wedge 1$-i. A line drawn vertically on the plane 1-i (f. 260, p. 277), that is, at right angles to the lower or upper side, is the hypothenuse of a right-angled triangle, the basal side of which triangle is parallel to a lateral axis b, and the vertical parallel to the vertical axis a. These sides have the ratios, therefore, of the two axes; and taking b=unity, a=tan A (or angle of triangle at base, or opposite a). This angle A equals the supplement of $O \wedge 1$-i; and therefore, calling this supplement S, a=tan S.

11. The value of the axis may also be obtained from the supplement (S') of the angle $O \wedge 1$, by the equation:

$$a = \tan S' \div \sec 45°;\ \text{whence}\ \log a = \log \tan S' - 10{\cdot}1505150.$$

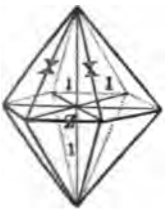
C. *Hexagonal System.* 12. This system differs from the Tetragonal in having *three* equal lateral axes (b) instead of two; the vertical (a) is at right angles to the lateral (fig. A).

13. In the Hexagonal section of the system the symmetry of the crystals is by sixes and twelves, as in figs. A to D; f. 440, p. 530; f. 527, p. 627. In f. B, 1 corresponds to a hexagonal pyramid of the fundamental series, and 1-2, $\frac{4}{3}$-2, 2-2, to similar pyramids of the intermediate series; I is the hexagonal prism of the former series, and i-2 that of the intermediate prism. $I \wedge I$=120°, $I \wedge i$-2=150°, i-2 $\wedge$ i-2, or. I,=120°.

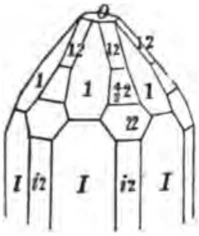
14. In the Rhombohedral section of the system, the planes 1, 2, 3, $\frac{1}{2}$, etc., are

planes of rhombohedrons, having for the vertical axis 1*a*, 2*a*, 3*a*, ½*a*, etc., 1*a* being the value of the axis in the fundamental rhombohedron, (*R*) (figs., p. 6). The angle of a rhombohedron mentioned is always that over a *terminal* edge, as that between the upper planes *R* of figure 141, p. 141. On gradually shortening the rhombohedron in fig. 141, it may become ½*R*, ¼*R*, and so on, till the length becomes 0,

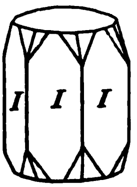
A



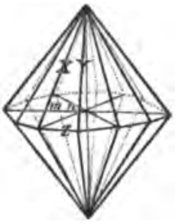
B



C



D



and the rhombohedron is reduced to a flat plane. Hence, starting from this plane (which corresponds to the basal plane of the rhombohedron or hexagonal prism), the rhombohedron as it elongates reaches the form of fig. 141; and continuing the elongation, the vertical axis doubles, trebles, and so on, till finally it becomes infinite, and the rhombohedron is then a six-sided prism. If a diminution in length now commences by planes inclined to the opposite extremities of the vertical axis, these planes correspond to another series of rhombohedrons which are distinguished by a minus (—). The planes

O....¼..1..2...*I* (or ∞) ....—2..—1..—½....*O*,

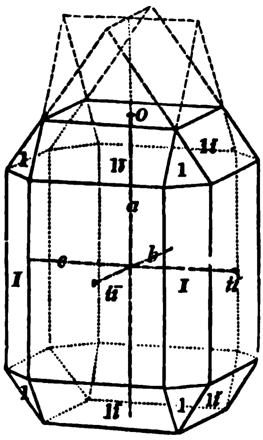
lie in a single vertical zone. Figs. 550, 551, p. 670, represent the forms *R*, −½, -2, −¼, 4, 13.

15. The value of the vertical axis *a* is obtained from the supplement:

Of $O \wedge 1\text{-}2$ (*S*) by the equation $a = \tan S$.
Of $O \wedge 1$ (*S′*) by the equation $a = \tan S' \div \sec 30°$.
The latter gives $\log a = \log \tan S' - 10{\cdot}0624694$.

D. *Orthorhombic System.* (Also called Rectangular, Prismatic, Trimetric, Ein und-einaxige.) 16. In the Orthorhombic system the three axes are unequal and intersect at right angles; and the three diametric planes, or those containing the axes, are consequently rectangular in intersection.

E



The annexed figure represents a rectangular prism with replaced edges and angles.

17. *a*, *b*, *c*, are the axes, of which *a* is the vertical, *b* the shorter lateral or *brachydiagonal*, *c* the longer lateral or *macrodiagonal*. *O* is the *basal* plane of the prism; *i*-ī the larger lateral plane, parallel to the *longer* lateral axis; *i*-ĭ the smaller lateral plane, parallel to the *shorter* lateral axis.

18. *I* are planes on the edges of the rectangular prism, which when extended would form a vertical rhombic prism, having its axes *b* and *c* in the ratio of 1*b* : 1*c*. It is therefore the *unit* or *fundamental vertical prism*.

19. 1-ī are planes parallel to the *longer* lateral axis, and having for the axes *a*, *b*, the ratio 1*a* : 1*b*; extended upwards they form a *dome* (so named from *domus*, a house), which is called the *macrodome*. The planes 1-ĭ

in a similar manner form what is called a *brachydome*, they being parallel to the *shorter* lateral axis; its axes *a*, *c*, have the ratio 1*a* : 1*c*, that is, the two diagonals of this horizontal prism have this ratio. These two domes are therefore the *unit domes* Their summit angles are of course supplements of their basal angles (or those over the vertical planes *i*-ī, *i*-ĭ).

20. If the axis *b*=1; half the obtuse angle of the prism *I* be called *X*; half the summit angle of the macrodome 1-ī, *Y*, and half the basal of the same *Z*; then we have for the values of the other axes *a* and *c*:

$$a = \cot Y = \tan Z. \quad c = \tan X.$$

$$\text{Further, } X = i\text{-}\bar{\imath} \wedge I - 90^\circ; \quad Y = O \wedge 1\text{-}\bar{\imath} - 90^\circ; \; Z = i\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath} - 90^\circ.$$

20. The planes 1 on the eight angles are planes of an octahedron, having for the axes *a*, *b*, *c*, the ratio 1*a* : 1*b* : 1*c*. It is therefore the unit or fundamental octahedron (1). Its pyramidal edges, if the octahedron were completed (as in f. 55, p. 20), would be of two kinds, two at each extremity opposite to the axis *c*, the longer lateral axis, and two opposite to *b*, the shorter lateral axis. The former is the macrodiagonal edge, the latter the brachydiagonal.

21. By doubling the length of the vertical axis, the lateral being fixed, we form the octahedron 2; by trebling it, the octahedron 3; by halving it, the octahedron ½; and so for the domes, doubling the vertical axis we have the dome 2-ī or 2-ĭ; by halving the same, the dome ½-ī or ½-ĭ, and so on. The letter *i*, as before explained, stands for infinity, and means that the plane is parallel to one of the axes; ī, that it is parallel to the longer lateral axis; ĭ, that it is parallel to the shorter lateral axis *i* or *I* alone, or as the initial letter in a symbol, signifies that the plane is parallel to the vertical axis. A plane *i*-ī is parallel both to the vertical and longer lateral; *i*-ĭ, both to the vertical and shorter lateral.

22. The octahedrons alluded to above have for the axes *b*, *c*, the ratio 1*b* : 1*c*, and belong to what is called the *fundamental* series. But others may exist with different ratios for *b* and *c*, and any value for *a*. If the ratio for *b*, *c*, is 1*b* : 2*c*, then, as *c* is the *longer* lateral axis, if the vertical axis is 1*a*, the octahedron is 1-2̄; or if the vertical axis is 3*a*, the plane is 3-2̄; or if ½*a*, it is ½-2̄. So for the ratio 3*b* : 1*c*; if the vertical axis is 1*a*, the octahedron is 1-3̆; or if 2*a*, it is 2-3̆; and if the vertical axis is infinite, the plane is *parallel* to the vertical axis, and the symbol is *i*-3̆. The first figure or letter in these symbols always refers to the vertical axis, and the second to one of the lateral axes.

23. The planes may thus be viewed as lying in vertical *zones*, a different zone for every ratio of the lateral axes *b* : *c*. Each series, or zone, terminates *above* in the basal plane of the prism, for which *a*=0, and *below* in a vertical prism, for which *a* is infinite. By taking the planes *i*-ī, *i*-ĭ, successively, for the basal plane *O*, there may be similar series of zones for each. The planes of a *zone* have their mutual intersections parallel to one another; and wherever a series of planes exists having such parallel intersections, the series is called a *zone*.

The small tables inserted in connection with the crystalline forms of some of the species of this and other systems of crystallization (pp. 27, 35, 338) consist of the vertical *zones* of occurring planes. The planes of a vertical zone have mutual *horizontal intersections* in the crystal. Consequently in a crystal not oblique the inclination of the basal plane, *O*, on any plane in a zone, subtracted from 270°, gives the inclination of the prismatic plane of the same zone on that plane, and the tangents of the supplemental angles of *O* on the planes of a zone vary as the coefficient of the vertical axis for each plane. Thus, suppose there are the planes 1-ī, 2-ī, 3-ī, take the supplement of *O* ∧ 1-ī (which, if *O* ∧ 1-ī is 124°, equals 180°—124°=56°); then the tangent of this angle, *doubled*, will be the tangent of the supplement of *O* ∧ 2-ī, and *trebled*, of the supplement of the angle of *O* ∧ 3-ī. The same for the planes 1, 2̆, 3̆, or 1-2̆, 2-2̆, 3-2̆, and so on; and if i-ī be made the base, then in the same manner the angles may be calculated for similar zones of planes terminating in i-ī; or if i-ĭ be made the base, for zones of planes terminating similarly in i-ĭ. So if the angles are given, the relations of the axes may be calculated by reversing the process

24. Making the brachydiagonal b=unity :

a=tan. suppl. $O \wedge 1$-ī; and calling the angle $I \wedge I$, over i-ĭ, X:
c=tan $\frac{1}{2}X$.

E. ***Monoclinic System.*** (Also called Hemiprismatic, Clinorhombic, Monoclinohedral, Zwei-und-eingliederige.) 25. In this system two of the axial intersections are rectangular, and one is oblique. In other words, the lateral axes are at right angles to one another; but one is *oblique* to the vertical axis, and the other at right angles to it.

26. If figure E on page xxv be taken as representing a monoclinic form in its usual position, then a will be the *vertical* axis; b the *inclined* lateral, called the *clinodiagonal*; c the other lateral, called the *orthodiagonal*. The angle $a \wedge b$, or the inclination of the vertical axis, is called the angle C.

27. The section of the crystal in which b, the clinodiagonal, and a lie is the *clinodiagonal section*; and that in which c and a lie is the *orthodiagonal section*. The vertical plane i-ī, of f. E, is parallel to the orthodiagonal section, and is lettered simply i-i; and the plane i-ĭ, of the same figure, is parallel to the clinodiagonal section, and is lettered i-ì. The angle $O \wedge$ i-i=C, or the inclination of the vertical axis; while $O \wedge$ i-ì=90°, and i-i ∧ i-ì=90°. The clinodiagonal section is *the plane of symmetry.*

28. The domes having the planes parallel to the clinodiagonal are called *clinodomes*, and are lettered with an accent over the ì, thus, 1-ì (1-ĭ in f. E), 2-ì.

29. The domes parallel to the orthodiagonal are *hemidomes*, the planes in front at top being unlike in inclination those in front below, each being a *hemidome*; one series is opposite the *acute* intersection of the axes, and is the *plus* series, lettered 1-i, 2-i, etc.; the other is opposite the *obtuse*, and is lettered −1-i, −2-i, etc.

30. The *octahedral* planes are all *hemioctahedral*, and + and — are used in the symbols in the same manner as in the symbols of the hemidomes. Thus in fig. E, if the angle between the upper O and the front plane i-i is obtuse, then the upper planes 1, 1, in front would be −1, −1, and the corresponding planes below, +1, +1, written usually 1, 1.

31. If the clinodiagonal b=1; half the front angle of the prism I (over i-i) be called X, half the summit angle of the clinodome 1-ì, X'; the supplement of i-i ∧ 1-i (=$O \wedge$ 1-i—C) be called μ; and supplement of $O \wedge$ 1-i be ν; and C be used as above explained; then,

$$c=\sin C \tan X. \qquad a=c \div \sin C \tan X'=\sin \nu \div \sin \mu=\sin (C-\mu) \div \sin \mu.$$

F. ***Triclinic System.*** (Also called Doubly Oblique, Tetartoprismatic, Anorthic, Ein-und-eingliederige.) 32. The three axes are unequal, and obliquely and unequally inclined. Angles of 90° and 135° are not met with in Triclinic crystals. Examples, figures on pp. 297, 338, 349.

33. The crystallographic symbols used in this work are essentially those of Naumann, the author of the system of crystallography which is followed. The only difference is that i, the initial of infinity, is substituted for the symbol ∞, and the P is dropped, it being in almost all cases unessential. Thus, P, $2P$, $4P2$, $\infty P \infty$, $\infty \breve{P}$, $\infty \breve{P}2$, $3\breve{P}2$, of Naumann, are P or 1, 2, 4-2, i-ĭ, i (or I), i-2̆, 3-2̆, of this work. And in the rhombohedral section of the hexagonal system, for R, $2R$, $3R$, R^2, $2R^2$, of Naumann, are here written, R, 2, 3, 1^2, 2^2. Moreover O or o is written for the basal plane. The distinction of capital or small letter in the symbols is mathematically of no importance.

34. In the orthorhombic system the *shorter* lateral axis is made the *unit* in this work. The axes are lettered a, b, c, in different systems, except in that of Miller (or

properly Whewell's), who uses the letters *h*, *l*, *k*, as "indices" referring to the axes in the order here written:

	Vertical.	Brachydiagonal.	Macrodiagonal
In this work	*a*	*b*	*c*
In Naumann	*a*	*c*	*b*
In Weiss and Rose	*c*	*a*	*b*
In Miller	*k*	*l*	*h*

For the tetragonal system the axes are the same, except that *b*=*c*. In the monoclinic:

	Vertical.	Clinodiagonal.	Orthodiagonal.
Naumann and this work	*a*	*b*	*c*
Weiss and Rose	*c*	*a*	*b*
Miller	*k*	*l*	*h*

The following are convenient simple rules for use in connection with crystallographic measurements and calculations:

35. If a plane, *p*, replaces the edge between any other two, *s*, *t*, making parallel intersections, the sum of the angles between *p* and the two planes *s*, *t*, equals 180 *plus* the inclination of *s* on *t*. If the planes *s*, *t*, meet at 90°, the sum of these angles equals 180°+90°=270°; and if the angles are equal, each is 135°; if the planes *s*, *t*, meet at 110°, the sum of the two angles equals 180°+110°=290°; and if one is 130°, the other will be 160°.

36. On p. xxvi, the relation between the symbols and the tangents of the inclinations of planes lying in zones between rectangular axes (which zones can be made to be vertical zones in one position or another of the crystal) is pointed out. The same method holds for all vertical zones in the tetragonal system, and for those that become vertical on putting the crystal on its plane *i-i*; also for all the zones which are made vertical by placing a monoclinic prism on its face *i-i*, that is the zone of clinodomes, the zone of vertical prisms, and all zones, then vertical, of hemioctahedrons; also for all the vertical zones of the hexagonal prism, and hence for the zone of rhombohedrons of any species, or vertical zones of scalenohedral planes.

37. For the transfer of *h l k* of Miller's system into the system of this work, take the reciprocals. Thus if symbol is 212, the reciprocals are $\frac{1}{2}$, 1, $\frac{1}{2}$, the last $\frac{1}{2}$ referring to the vertical axis. As the relation of the lateral axes should be in whole numbers, double the whole and it gives 1 : 2 : 1; whence the plane is that which would be here designated 1-2. So 1 : 1 : 3 becomes 1 : 1 : $\frac{1}{3}$, whence the symbo $\frac{1}{3}$; or 315 becomes $\frac{1}{3}$, 1, $\frac{1}{5}$, or 1, 3, $\frac{3}{5}$; whence $\frac{3}{5}$-3; and in the orthorhombic system the 3 in $\frac{1}{3}$-3 would have the short mark, or be written $\frac{3}{5}$-$\breve{3}$; while 135 would give the symbol $\frac{3}{5}$-$\breve{3}$.

38. In hexagonal forms the change is less simple, and the method for it is hardly intelligible to one not knowing something of both systems. The axes of Miller, instead of being those of fig. A, p. xxv, are lines drawn through the centre normal to (that is, at right angles to) the alternate faces of the pyramid; they are therefore *three* in number, and the planes are thus referred to axes parallel to the rhombohedral edge. The planes in fig. A, according to Naumann's system, are all of one kind in the *hexagonal* section of the hexagonal system, but of two kinds, *R* and −*R* (or 1 and −1) in the *rhombohedral* section. In Miller's system they are of two kinds in both sections, the distinction between the two sections not being entertained.

The axes *a*, *b*, *c*, of any plane in the hexagonal system of Naumann, have the following values in terms of *h k l* of Miller:*

---

* Furnished the author for this place by Prof. J. P. Cooke, of Harvard.

$$a=\frac{1}{h+k+l}\sqrt{\frac{3\,(1+2\cos\gamma)}{2\,(1-\cos\gamma)}}\qquad b=\frac{1}{l-k}\qquad c=\frac{1}{l-h}$$

But in using these equations strict attention must be paid to the signs, as it illustrated in the examples below. The angle γ is the angle between the axes in Miller's system, which equals the facial angle of the rhomb face at the vertex of the rhombohedron *R*.

The equations give the true ratios of Naumann's axes; but these ratios often have to be reduced to whole numbers, or otherwise modified, to obtain precisely the values used in Naumann's symbol. The second member in the equation for *a* gives the length of the axis *ma* in any form; the *first* member in it is all that is required for the value of *m* in the symbol, while the second is the value of *a*.

The following are some examples:

In f. 564 (p. 672), plane *R*, which is 100 of Miller, gives, on substituting the values of *h k l*, and working the equations, $a:b:c=1:i$ (infinity) $:-1$. The parameters of the plane in Naumann's system for the vertical and three lateral axes are $1:1:1:i$.

The plane *i*, to the right, is $2\bar{1}\bar{1}$ of Miller; whence $a:b:c=i:i:-3$, which, since *a* and *b* are each infinity, is equivalent to $i:i:-1$.

The plane -2, to the right, is $1\bar{1}1$ of Miller; whence $a:b:c=1:\frac{1}{2}:i=2:1:i$; the Naumann ratio for this plane is $2:1:1:i$.

Plane $-\frac{5}{4}$ is $33\bar{2}$ of Miller; whence $a:b:c=\frac{1}{4}:\frac{1}{5}:-\frac{1}{5}=\frac{5}{4}:-1:-1$.

The left upper plane 1^3 is $20\bar{1}$ in Miller; whence $a:b:c=1:-1:-\frac{1}{3}=3:-3:-1$, giving the Naumann symbol 3-3, from which comes its equivalent scalenohedral symbol 1^3.

The left upper plane $\frac{1}{2}^3$ is Miller's 310; whence $a:b:c=\frac{1}{4}:-1:-\frac{1}{3}=\frac{3}{4}:-3:-1$; giving the Naumann symbol $\frac{3}{4}$-3, and its equivalent $\frac{1}{2}^3$.

The right upper of the two adjoining planes, $\frac{1}{2}^3$ in f. 564, is 301 of Miller; whence $a:b:c=\frac{1}{4}:1:-\frac{1}{2}$. This is apparently a different result from the last. But calculating the length of the fourth of Naumann's parameters, it gives $h=n+(n-1)=\frac{1}{2}+(-\frac{1}{2}-1)=\frac{1}{2}$. from which it follows that the parameters of the plane are $\frac{1}{4}:1:\frac{1}{3}:-\frac{1}{2}$; and on calculating the fourth parameter in the preceding, $\frac{1}{2}$ would be obtained, proving that both are really the same plane.

5. NOMENCLATURE.

1. The termination *ites* or *itis* (the original of *ite*) was used, according to system, among the Greeks, and from them among the Romans, in the names of stones, it being one of the regular Greek suffixes. It was added (as *ite* in these recent times) to the word signifying a *quality*, *constituent*, *use*, or *locality* of the stone.

Some of the examples are: *Hæmatites*, from the red color of the powder *Chloritis*, from the green color; *Steatites*, from the greasy feel; *Dendritis*, from a resemblance to a tree or branch; *Alabastritis*, for the stone out of which a vase called an *alabastron* was made; *Basanites*, from the word for touchstone; *Siderites*, from the word for iron; *Argyritis*, from the Greek for silver; *Syenitis*, from the *locality*, Syene in Egypt; *Memphitis*, for a marble from Memphis in Egypt.

2. The only modern kind of name not in vogue in Pliny's time is that after persons.

Werner appears to have been the first to introduce personal names into mineralogy. The earliest example, as far as ascertained, was his naming what von Born had called *Green Mica* (Mica viridis), *Torberite*, after its investigator, the chemist Torber Bergmann (more correctly written *Torbernite* by some mineralogists of last century, as Bergmann wrote his name in Latin, the language of his scientific works, Torbernus Bergmann). The name encountered objections; and Werner, in view of Bergmann's announcement (after some incorrect trials) that the mineral was a *copper* ore, substituted in 1789 the name *Chalcolite*. He, however, immediately afterward (early in 1790) showed that he saw nothing bad in the style of name by designating other new species *Prehnite* and *Witherite*, the former after Col. Prehn, the discoverer, and the latter after Dr. Withering, the discoverer and analyst of the species. The same year Estner, a mineralogist of Vienna, issued a pamphlet against the Werner school, with the title "Freymüthige Gedanken über Herrn Inspector Werner's Verbesserungen in der Mineralogie" etc. (64 pp. 16mo, 1790), in which he makes light of Werner's labors in the science, and under the head of *Prehnite* ridicules this method of creating a paternity, and providing the childless with children to hand down their names to posterity (p. 25). Such names were, however, too easily made, too pleasant, as a general thing, to give and receive, and withal too free from real objection, to be thus stopped off, and they have since become numerous, even Vienna contributing her full share toward their multiplication.

As a part of the history of mineralogical nomenclature, it may be here added that Werner, when it was proved that his *chalcolite* was an ore of uranium with but little copper, instead of a true ore of copper, dropped the name entirely, and called the mineral simply *Uranglimmer* (Uranium mica); and Karsten, in his reply to Abbé Estner (Berlin, 1793, 80 pp. 12mo), makes out of the necessary rejection of chalcolite an argument against chemical names, and in favor of names after persons, as the latter could never turn out erroneous in signification.

Werner, in an article written in defence of his introduction of this class of names (Bergm. J., i. 103, 1790), mentions the case of *Obsidian* (more properly *Obsian*) as a precedent from Pliny, Obsian being, as Pliny states, the reported discoverer of the substance in Ethiopia. But this is not strictly an example. For Pliny uses *Obsian* not as a substantive, but as an adjective; the mineral was not *Obsian*, but *Obsian glass* or *Obsian stone; vitrum obsianum, lapis obsianus*, and *obsiana* [vitra], occurring in the course of the paragraph. The addition of the termination *ite* to Obsian would, according to mineralogical method, make a name equivalent to Pliny's *lapis obsianus*. Names of persons ending in *an* (as Octavian, Tertullian) were common among the Romans; and this is so far reason for avoiding the termination in names of stones.

Some critics question the existence of the reputed Obsius, and reject Pliny's explanation.

3. The ancient origin of this termination *ite*, its adoption for most of the names in modern mineralogy, its distinctive character and convenient application, make it evidently the true basis for uniformity in the nomenclature of the science.

4. If any other termination in addition is to be used, it should be so only *under system*; that is, it should be made characteristic of a particular natural group of species, and be invariably employed for the names in that group; and its use should not be a matter of choice or fancy with describers of species.

As a matter of fact, several other terminations are in use, but wholly without reference to any such system. The most common of them is *ine*; but it has not been employed for any particular division of minerals, and it could not now be so restricted; it belongs by adoption and long usage to chemistry, and should be left to that science.

5. In order then that the acquired uniformity may be attained, changes should be made in existing names, when it can be done without great inconvenience.

Names like *Quartz*, *Garnet*, *Gypsum*, *Realgar*, *Orpiment*, with the names of the metals and gems, which are part of general literature, must remain unaltered. *Mica* and *Feldspar*, equally old with Quartz, have become the names of *groups* of minerals, and are no longer applied to particular species. *Fluor* was written *fluorite* last century by Napione. *Blende*, although one of the number that might be allowed to stand among the exceptions, has already given place with some mineralogists to *Sphalerite*, a name proposed by Haidinger (because blende was applied also to other species) in 1845, and signifying *deception*, like Blende. Galena was written *Galenite* by von Kobell some years since. Orthoclase, Loxoclase, Oligoclase might be rightly lengthened to *Orthoclasite*, etc. But the termination *clase* (from the Greek for *fracture*) is peculiar to names of minerals, and the abbreviated form in use may be allowed to stand for species of the Feldspar group. It seems better that it be avoided elsewhere. Many other examples will be found by the reader in the pages of this volume.

In the course of the last century, when the science of minerals was taking shape, and progress in chemistry was helping it forward, there was an effort on one side to introduce, under the influence of Linnæus, the double names of Botany and Zoology; and on the other, under the influence of Cronstedt and Bergmann, names expressive of chemical composition, as far as it was ascertained; and the two methods have had their advocates till late in the present century. But at the same time, the necessity of single names was recognized by most of the early mineralogists; and in the spirit of the system which had made its appearance among the Greeks and Romans out of the genius of the Greek language, they almost uniformly adopted for the new names the termination *ite*.

Thus we have from Werner the names Torberite, Chalcolite, Graphite, Prehnite, Witherite, Boracite, Augite, Pistacite, Pinite, Aragonite. Apatite, Leucite, Cyanite (Kyanite); and from other sources in the same century, Zeolite, Actinolite, Tremolite, Coccolite, Arendalite, Baikalite, Melanite, Staurolite, Lepidolite, Cryolite, Chiastolite, Collyrite, Agalmatolite, Sommite, Moroxite, Pharmacolite, Strontianite, Delphinite, Titanite, Ceylanite, Gadolinite, Rubellite, Sahlite, Wernerite, Scapolite, Mellite, etc.

The termination *ine* was also adopted for a few names, as Tourmaline, Olivine, Mascagnine, Serpentine; and *an* in Vesuvian; but the great bulk of the names were systematically terminated in *ite*.

With the opening of the present century (in 1801), Haüy came forward with his great work on Crystallography, and in it he brought out a variety of new names that defy all system, having nothing of the system of the earlier science, and no substitute of his own. Forgetting that the unity of law which he had found in nature should be a feature of scientific language, he gave to his names the following terminations:

ane, in Cymophane; *ase*, in Euclase, Idocrase, Anatase, Dioptase; *aste*, in Pleonaste; *age*, in Diallage; *ene*, in Disthene, Sphene; *gene*, in Amphigene; *ide*, in Staurotide; *ime*, in Analcime; *ole*, in Amphibole; *ome*, in Aplome, Harmotome; *ose*, in Orthose; *ote*, in Actinote, Epidote; *yre*, in Dipyre; *ype*, in Mesotype. And the true mineralogical termination *ite* he admitted only in the few following: Axinite, Moionite, Pycnite, Stilbite, Grammatite.

Haüy had commanded so great and so general admiration by his brilliant discoveries in crystallography, and by the benefits which he had thus conferred on mineralogical science, that his names with their innovations were for the most part immediately accepted even beyond the limits of France, although a number of them were substitutes for those of other authors. Some of Werner's names were among the rejected; and a break was thus occasioned between German and French mineralogy, which will not be wholly removed until the rule of priority, properly restricted, shall be allowed to have sway.

The *substitutes* among Haüy's names in the 1st edition of his Crystallography (1801) are the following:

Amphibole, for *Hornblende* of last century and earlier.
Orthose, for *Feldspar*.
Pyroxene, for *Augite* of Werner, and *Volcanite* of Delamétherie. [Delamétherie was a contemporary of Haüy at Paris, the author in 1792 of an edition of Mongez's *Manuel du Minéralogiste* (after Bergmann's Sciagraphia); in 1797, of an ambitious speculative work entitled *Théorie de la Terre*, the first two volumes of which consisted of a Treatise on Mineralogy; in 1811, 1812, of *Leçons de Minéralogie*, in 2 vols., and for a number of years principal editor of the *Journal de Physique*. He gave offence to Haüy by some of his early publications. Haüy's mineral Euclase is described in full by Delamétherie in the *Journal de Physique* for 1792 (some years in advance of Haüy's description of it), without crediting the name or anything else to Haüy; but five years later, in his *Théorie de la Terre*, he inserts the species with full credit to Haüy.]
Cymophane, for *Chrysoberyl* of Werner.
Idocrase, for *Vesuvian* of Werner.
Pleonaste, for *Ceylanite* of Delamétherie.
Disthene, for *Cyanite* of Werner.
Anatase, for *Octahedrite* of de Saussure, and *Oisanite* of Delamétherie.
Sphene, for *Titanite* of Klaproth.
Nepheline, for *Sommite* of Delamétherie.
Triphane, for *Spodumene* of d'Andrada.
Amphigene, for *Leucite* of Werner.
Actinote, for *Actinolite* of Kirwan, and *Zillerthite* of Delamétherie.
Epidote, for *Thallite* of Delamétherie, *Delphinite* of de Saussure, and *Arendalite* of Karsten
Axinite, for *Yanolite* of Delamétherie.
Harmotome, for *Andreolite* of Delamétherie.
Grammatite, for *Tremolite* of Pini.
Staurotide, for *Staurolite* of Delamétherie, and *Grenatite* of de Saussure.
And. later, *Paranthine*, for *Scapolite* of d'Andrada, and *Rapidolite* of Abildgaard.

Part of the changes were made with good reason; but others were wholly unnecessary. Haüy was opposed to names from localities, and hence several of the displacements. He objected also to names based on variable characters, and characters not confined to the species. Moreover, as his pupil, Lucas, observes (in giving reasons for rejecting the name *Scapolite* and substituting *Paranthine*), "le vice du mot *lite*, qui s'applique à toutes les pierres, ne pouvoient plus convenir à cette substance du moment où elle seroit reconnue pour un espèce." Haüy's own names are remarkable, in general, for their indefiniteness of signification, which makes them etymologically nearly as good for one mineral as another, and very bad for almost none; as, for example, *Diallage*, which is from the Greek for *difference; Analcime*, from *weakness* in Greek; *Orthose*, from *straight* in Greek; *Epidote*, from *increase* in Greek; *Anatase*, from *erection* in Greek, interpreted by him as equivalent to *length*; *Idocrase*, from *I see mixture* in Greek, etc. His name *Pyroxene*, which he defines *hôte ou étranger dans le domaine du feu*, is an unfortunate exception, as others remarked, the mineral being the most common and universal constituent of igneous rocks.

Beudant succeeded Haüy, and had the same want of system in his ideas of nomenclature. Finding occasion to name various mineral species which till then had only chemical names, he adopted Haüy's method of miscellaneous terminations, but indulged in it with less taste and judgment and with little knowledge of the rules of etymology. In his work we find the termination *ese*, in Apherese, Aphanese, Neoctese, Acerdese, Mimetese; *ise*, in Leberkise, Sperkise, Harkise (only German words Gallicized); Melaconise, Zinconise, Crocoise, Stibiconise, Uraconise; *ose*, in Argyrose, Argyrythrose, Psaturose, Aphthalose, Rhodalose, Siderose, Elasmose, Exanthalose, Cyanose, Melinose, Disomose; *ase*, in Neoptase, Discrase; *ime*, in Ypoleime; *ele*, in Exitele; while names ending in *ine* are greatly multiplied.

In Germany, the tendency has always been to uniformity through the adoption of the termination *ite*. Breithaupt has been somewhat lawless, giving the science his Plinian, Alumian, Sardinian, Asbolan, etc.; his Castor and Pollux; Glaucodot, Homichlin, Orthoclase, Xanthocon, etc.; still, far the larger part of his numerous names are rightly terminated. Haidinger's many names are always right and good.

6. In forming names from the Greek or Latin the termination *ite* is added to the genitive form after dropping the vowel or vowels of the last syllable, and any following letters. Thus, μέλας makes μέλανος (*melanos*) in the genitive, and gives the name *melanite*. The Greek language is the most approved source of names.

7. In compounding Greek words the same elision of the Greek genitive is made for the first word in the compound, provided the second word begins with a vowel; if not, the letter *o* is inserted. Thus, from πῦρ, genitive πυρός (*puros*), and ὀρθός (*orthos*), comes pyrorthite; and from the same and ξένος (*xenos*) comes pyroxene.

8. The liberty is sometimes taken in the case of long compounds to drop a syllable, and when done with judgment it is not objectionable; thus *melaconite* has been accepted in place of *melanoconite*. But *magnoferrite* (as if from the Latin *magnus*, great, and ferrum, *iron*), for a compound of *magnesia* and iron, or *calcimangite* for one containing lime and *manganese*, are bad.

9. In the transfer of Greek words into Latin or English, the κ (*k*) becomes *c*, and the υ (*u*) becomes *y*.

10. In the formation of the names of minerals, the addition of the termination *ite* to proper names in modern languages (names of places, persons, etc.), or names of characteristic chemical constituents, is allowable; but making this or any other syllable a suffix to *common* words in such languages is barbarous.

11. Names made half of Greek and half Latin are objectionable; but names that are half of Greek or Latin and half of a modern language are intolerable.

12. *Law of Priority.* The law of priority has the same claim to recognition in mineralogy as in the other natural sciences. Its purpose is primarily to secure the stability, purity, and perfection of science, and not to insure credit to authors.

13. *Limitations of the Law of Priority.* The following are cases in which a name having priority may properly be set aside:

a. When the name is identical with the accepted name of another mineral of earlier date.

b. When it is glaringly false in signification; as when a red mineral is declared in its name to be black; *e. g.*, *Melanochroite* (p. 630); or when a honey-yellow mineral is made to be ashen; *e. g.*, *Melinophane* (p. 263).

c. When it is put forth without a description.

d. When published with a description so incorrect that a recognition of the mineral by means of it is impossible; and in consequence, and because also of the rarity of specimens, the same species is described under another name without th describer's knowledge of the mineral bearing the former name. When, on the contrary, a badly described but well-known old mineral is redescribed correctly, there is no propriety in the new describer changing the old name.

According to this canon it might seem right that the name *Emerylite* should have been substituted for *Margarite* (p. 506). Yet margarite, though incorrectly described, was a species well known in cabinets, and Dr. Smith manifested his appreciation of the true interests of science—the end of all canons—in adopting the old name so soon as he had ascertained by further research the identity of his species with margarite.

e. When the name is based on an uncharacteristic variety of the species. Thus *Sagenite* was properly set aside for *Rutile* (p. 159).

f. When the name is based upon a variety so important that the variety is best left to retain its original name; particularly where this and other varieties of the species, introduced originally as separate species, are afterwards shown by investigation to belong to a common species. Thus, the earlier name *Augite* is properly retained as the name of a variety, and Haüy's later name *Pyroxene* accepted for the group, as explained on p. 214.

g. When a name becomes the designation of a group of species: as *Mica*, *Chlorite*.

h. When the name is badly formed, or the parts are badly put together: as when the terminal *s* of a Greek word is retained in the derivative; *e. g.*, *aphanese* from ἀφανής; *Melaconise* from the Greek for *black* and κόνις; *Rhodalose* from the Greek for *rose-colored* and ἅλος (halos), the genitive of ἅλς, *salt*. The last word is bad not only in termination but in wanting an *h* before the *a*, and strictly an *o* after the *d*. Also *Siderose* (spathic iron), *Argyrose* (silver glance), *Chalcosine* (copper glance), from, respectively, σίδηρος, ἄργυρος, χαλκός. The ancient Greeks showed us how the derivatives from these words should terminate by writing them *Sideritis*, *Argyritis*, *Chalcitis*.

Ignorance or carelessness should not be allowed to give perpetuity to its blunders under any law of priority.

i. When a name is intolerable for the reasons mentioned in §§ 10, 11, as Harkise, from the German Haarkies (hair pyrites); *Kupaphrite*, from the German *Kupferschaum*; *Bleinierite*, from the German *Blei-Niere*.

j. When a name has been lost sight of and has found no one to assert its claim for a period of more than fifty years; especially if the later name adopted for the species has become intimately incorporated with the structure of the science, or with the nomenclature of rocks. Thus, although *Thallite* and *Delphinite* antedate *Epidote*, it is not for the good of science that Epidote should be thrown aside. But where a name has not this importance, and is unexceptionable, the law of priority may be allowed to have its course.

The right to recognition, under this canon, where the names are those of the original describer of the species, is strong. But with regard to names introduced for well-known old species to replace earlier chemical or provincial names, the claim is feebler; and if the names are not strictly according to rule, or are unsatisfactory in mode of publication, they may be more freely modified, abbreviated if desirable, or rejected altogether. Prof. Chapman's "Practical Mineralogy," published in England in 1843, affords examples of the latter kind, and has occasioned some embarrassment. The work was by an author at that time unknown in the science (the preface says, an engineer, and "a very young man"); it was small, of limited circulation, and practical in its object, and therefore one in which new names for old species would not naturally be looked for. In 1845, Haidinger, then already a veteran in the science, the author of several works on mineralogy, and of numerous researches in its various departments, issued his "Handbuch," in which also a number of old species were provided with mineralogical names. Through Chapman's publication Haidinger's *Breithauptite* is anticipated two years by Chapman's *Hartmannite*; his *Freieslebenite*, by the latter's *Donacargyrite*; his *Chromite*, by the latter's *Chromoferrite*; his *Cuprite*, by *Kuberite*; and so on. Chapman's names have ever since remained unknown or forgotten; while Haidinger's have had general acceptance among the mineralogists of Europe, and are now the current names. It has seemed that, after so long a period of oblivion, it would be doing no good to science to div place the latter, and a useless endeavor to attempt it. The later English Mineralogies of Nicol (1849), Brooke & Miller (1852), and Greg & Lettsom (1858), contain none of Chapman's names.

k. Where the adopted system of nomenclature in the science is not conformed to. In accordance with this last principle, the author, believing that the system demands that the names of species should have as far as possible, as above explained, the common termination *ite*, has changed, accordingly, a number of the names in the course of this volume.

14. It has appeared desirable that the names of rocks should have some difference of form from those of minerals. To secure this end, the author has written the final syllable *ite* of such names with a *y*; thus Diorite, Eurite, Tonalite, etc., are written *Dioryte*, *Euryte*, *Tonalyte*. The *y* is already in the name *Trachyte*. The author has allowed Granite and Syenite to remain as they are ordinarily written, since they are familiar names in common as well as in scientific literature.

See further, on Nomenclature, the excellent Mineral-Namen of v. Kobell.

6. BIBLIOGRAPHY.

The following catalogue contains the titles of the works which are referred to in the following pages, with their abbreviated titles. As the value of these references, and of the various historical conclusions deduced, depends on their having been derived from the original publications themselves, the abbreviated titles of the Journals and other works which the author has had by him for consultation are put in black letter; while the rest, that is of those he has not seen, are in small capitals. Some titles also are added of works consulted, but not referred to. Many other titles might have been inserted, a considerable number from the author's library; but they would swell the list without increasing much its value.

The abbreviations of the more important words in the abbreviated titles, and of the names of the States in the United States (some of which are in the titles and other in the observations on minerals), are as follows:

Abbreviated words.—*Am.*, American; *Can.*, Canada; *Ch.*, Chemistry, Chemical, Chemie, Chimie; *Fr.*, French; *G.*, Geological, Geology, Geologie, Geologischen; *Germ.*, German; *J.*, Journal; *M.*, Mines; *Min.*, Mineralogy, Mineralogie, Mineralogical; *pt.*, in part; *Q.*, Quarterly; *Sc.*, *Sci.*, Science; *Soc.*, Society; *ZS.*, Zeitschrift.

Abbreviated names of the United States.—*Ala.*, Alabama; *Ark.*, Arkansas; *Cal.*, California; *Ct.*, *Conn.*, Connecticut; *Del.*, Delaware; *Ga.*, Georgia; *Ill.*, Illinois; *Ind.*, Indiana; *Kan.*, Kansas; *Ky.*, Kentucky; *Me.*, Maine; *Mass.*, Massachusetts, *Md.*, Maryland; *Mich.*, Michigan; *Minn.*, Minnesota; *Miss.*, Mississippi; *Mo.*, Missouri; *N. Car.*, North Carolina; *N. H.*, *N. Hamp.*, New Hampshire; *N. J.*, New Jersey; *N. Y.*, New York; *O.*, Ohio; *Penn.*, Pennsylvania; *R. I.*, Rhode Island; *S. Car.*, South Carolina; *Tenn.*, Tennessee; *Va.*, Virginia; *Vt.*, Vermont.

Other abbreviations are explained below. The catalogue is divided into three parts: 1. Periodicals not issued by Scientific Societies; 2. Publications of Scientific Societies; 3. Independent works or publications.

In giving abbreviations of the publications of Societies, *the name of the place where the Society is established is in all cases stated*, and, for the sake of uniformity, it is made the *last* word in the abbreviated title, a method which it were well if always followed. For the prominent journals, and the serials of some societies, the tim of publication of the successive volumes, or of the volumes of every successive fiv years, is stated.*

---

* A very useful table, giving the date of publication of each volume of the journals here referred to, might easily be constructed from the facts stated. It may be made on paper ruled in squares,

1. *Periodicals not issued by Scientific Societies.*

Afh., or Afhandl. Afhandlingar i Fisik, Kemi och Mineralogie, etc., utgifne af Hisinger & Berzelius. Vol. 1, 1806; 2, '07; 3, '10; 4, '15; 5, 6, '18

Am. J. Sci. American Journal of Science and Arts. 1st series, 50 vols., 8vo; conducted by B Silliman, 1818–1839; with B. Silliman, Jr., from 1840. Four numbers to vol. 1, and two to subsequent vols. Vol. 1, No. 1, Aug., 1818; No. 2, Jan., '19; No. 3, Mar., '19; No. 4 June, '19; vol. 2, Ap., Nov., '20: 3, Feb., May, '21; 4, Oct., Feb., '21, '22; 5, June, Sept. '22; 6, Jan., May, '23; 7, Nov., Feb., '23, '24; 8, May, Aug., '24; 9, Feb., June, '25; 10, Oct., Feb., '25, '26; 11, June, Oct., '26; 12, 13, Mar., June, Sept., Dec., '27; afterward regularly on the first of April, July, Oct., Jan.: vols. 14, 15, in '28, '28–'29; 24, 25, in '33, '33–'34; 34, 35, in '38, '38–'39; then regularly, Jan., May, July, Oct., 36, 37, in '39; 38, 39, in '40; 48, 49, in '50; 50, Index volume.

2d ser., by the same and James D. Dana, until 1865, after which, by B. Silliman and James D. Dana; from 1851, aided by A. Gray and W. Gibbs; '53 to '66, by L. Agassiz; from '63, by G. J. Brush and S. W. Johnson; from '64, by H. A. Newton. 2 vols ann.; 1, 2, 1846; 11, 12, '51; 21, 22, '56; 31, 32, '61; 41, 42, '66; whence, 49, 50, 1870. An index to 10 vols. in each vols. 10, 20, 30, etc.

Ann. Ch. Annales de Chemie. 8vo, Paris, vols. 1–3, 1789; 4–7, '90; 8–11, '91; 12–15, '92; 16–18, '93; 19–24, '97; 25–27, '98; 28–31, '99; then regularly 4 v. ann.; 32–35, 1800; 52–55, '05; 72–75, '10; 92–95, 96, '15, an Index to vols. 31 to 60 inclusive. Continued in the Ann. Ch. Phys. (q. v.).

Ann. Ch. Pharm. Annalen der Chemie und Pharmacie; by Wöhler and Liebig; from vol. 77, by Wöhler, Liebig, and Kopp, and called *new series*. 8vo, Leipzig and Heidelberg, 4 vols. ann. Vol. 1–4, 1832; 13–16, '35; 33–36, '40; 53–56, '45; 73–76, '50; 93–96, '55; 113–116, '60; 133–136, '65; 153–156, '70. Supplementband, 1, 1861; 2, '62, '63; 3, '64; 4, '65, '66.

Ann. Ch. Phys. Annales de Chemie et de Physique; at first by Gay Lussac et Arago. 8vo, Paris; 3 vols. ann.; 1–3, 1816; 16–18, '21; 31–33, '26; 46–48, '31; 61–63, '36; 73–75, '40. Vols. 67–75 made 2d ser., and numbered 1–9. 3d ser., 1–3, '41; 16–18, '46; 31–33, '51; 46–48, '56; 61–63, '61; 67–69, '63. 4th ser., 1–3, 1864; 16–18, '69.

Ann. d. M. Annales des Mines. 8vo, Paris. Begun in 1816 as sequel to Journal des Mines; 1 vol. a year until 1825, and subsequently 2 vols. a year. Vol 1, 1816; 6, '21; 10, 11, '25; 12, 13, '26. 2d ser., 1, 2, '27; 9, 10, '31. 3d ser., 1, 2, '32; 19, 20, '41. 4th ser., 1, 2, '42; 19, 20, '51. 5th ser., 1, 2, '52; 19, 20, '61. 6th ser., 1, 2, '62.

Ann. Mus. d'Hist. Nat. Annales du Muséum d'histoire naturelle par les Professeurs de cet établissement, MM. Haüy, Fourcroy, Vauquelin, Desfontaines, A. L. de Jussieu, Geoffroy, Lacepède, etc. 4to, Paris; vols. 1–20, 2 a year, 1803–1815.

Ann. Phil. Annals of Philosophy. 2 vols. ann., 8vo, London. 1st ser. by Thos. Thomson; vols. 1, 2, 1813; 11, 12, '18; 15, 16, '20. 2d ser., vols. 1, 2, 1821; 11, 12, '26. Then merged in Phil. Mag. (q. v.).

B. H. Ztg. Berg- und hüttenmännische Zeitung. 4to, Liepzig, 1 vol. ann. Begun by Hartmann, and sometimes called Hartmann's Zeitung. Now edited by B. Kerl and F. Wimmer. Vol. 1, 1842; 4, '45; 9, '50; 14, '55; 19, '60; 24, '65; 29, '70.

Baumg. ZS. Zeitschrift f. Physik und Mathematik; edited by Baumgartner and Ettingshausen. 10 vols, 8vo, 1826–1832, Wien.

Bergm. J. Bergmännisches Journal; ed. by A. W. Köhler. 12mo, Freyberg, Sax. 1, 2, 1788; 1, 2, '89; so to '92; 1, 2, '93, by Köhler and Hoffmann. Afterward, Neues Bergm. J., of K. & H.; 1, 1795; 2, '98; 3, 1802; 4, '16. Contains papers by Werner, Hoffmann, Klaproth, and much on mineralogy.

Bibl. Univ. Bibliothèque Universelle de Genève. Begun in 1816. In 1846, 4th series of 36 vols. commenced, and the scientific part of the Review takes the title, Archives des Sciences physiques et Naturelles. 5th series commenced in 1858.

Bruce Am. Min. J. The American Mineralogical Journal; conducted by Archibald Bruce, M.D. Only 1 vol., 8vo. Begun Jan., 1810; No. 1, 62 pp., 1810, and 2, to p. 126, '10; 3, to p. 190, '11; 4, to end, p. 270, '13.

Can. Nat. Canadian Naturalist and Geologist. 8vo, Montreal. Vol. 1, 1856; 5, '61; 8, '63; 2d ser., vol. 1, '64; 2, '65; 3, '66.

---

having the years in succession, beginning with 1770, at the top of the columns of squares, the titles of the several journals to the left, and the number of the volume or volumes of each issued each year in the column for that year. Such a table was constructed by the author, with reference to the preparation of this edition. It would be a vast benefit to science if a series of such tables, containing all journals of importance, and also the publications of societies, could be made out and engraved, and thus placed within the reach of students in science.

Can. J. Canadian Journal of Industry, Science, and Art. Toronto, Canada; 2d ser., vol. 1 1856; 5, '60; 10, '65; 11, '66, '67.

Ch. Gaz. Chemical Gazette, by W. Francis. 8vo, London; 1 vol. ann. after vol. 1, of 1842, 3

Ch. News. Chemical News; edited by W. Crookes. Sm. 4to, London. 2 v. ann; vols. 1, 2 1860; 11, 12, '65; 21, 22, '70.

Crell's Ann. Chemische Annalen: by L. Crell. 40 vols., 12mo, Helmstadt u. Liepzig; vols. numbered 1, 2, for each year, from 1784 to 1803 inclusive.

Dingler J. Polytechnisches Journal; by J. G. & E. M. Dingler. 3 vols. ann., 8vo, Augsburg. Begun in 1820; vol. 187, in 1868.

Dublin Q. J. Sci. Dublin Quarterly Journal of Science; edited by Rev. S. Haughton. 6 vols, 8vo, 1861–'66, Dublin.

Ed. J. Sci. Edinburgh Journal of Science; edited by D. Brewster (often called Brewster's J.). 8vo, Edinburgh, 2 vols. ann. 1st ser., vol. 1, 1824; 2, 3, '25; 6, 7, '27; 10, '29. 2d ser., vol. 1, 1829; 2, 3, '30; 4, 5, '31; 6, '32. Merged in Phil. Mag.

Ed. Phil. J. Edinburgh Philosophical Journal; edited by Brewster and Jameson. 8vo, 2 vols. ann.; vol. 1, 1819; 2, 3, '20; 6, 7, '22; 10, '24; edited by Jameson alone, 11, 1824; 12, 13, '25; 14, '26. Becomes Ed. N. Phil. J. (q. v.).

Ed. N. Phil. J. Edinburgh New Philosophical Journal; edited by Prof. Jameson (often called Jameson's Journal). 8vo, 2 vols. ann. 1st ser., vol. 1, 1826; 2, 3, '27; 12, 13, '32; 22, 23, '37; 32, 33, '42; 42, 43, '47; 52, 53, '52; 56, 57, '54. 2d ser., vols. 1, 2, 1855; 11, 12, '60; 19, 20, '64. Here ends.

Erman's Arch. Archiv für wissenschaftliche Russland. Begun in 1841; 1 vol. ann. Vol. 1, 1841; 11, '51; 21, '61, etc.

Gehlen's J. Neues allg. Journal der Chemie; by A. F. Gehlen. 6 vols., Berlin; 1, 1803; 2, 3, '04; 6, '06. 2d ser., under the title Journal für die Chemie und Physik und Mineralogie, 9 vols., Berlin; 1, 2, 1806; 5, 6, '08; 9, '10. Afterward, Schweigger's Journal (q. v.) began at Nuremberg.

Gilb. Ann. Annalen der Physik; conducted by L. W. Gilbert. 8vo, Leipzig, 30 vols.; 1st series, 1799–1808; then 30 vols., 2d ser., 1809–'18; then Annalen d. Phys. und der Physikalischen Chemie, 16 vols., 3d ser., 1819–'23. The vols of the several series usually counted consecutively; 1, 2, 1799; afterward 3 vols. a year, 3–6, 1800; 13–15, '03; 28–30, '08; 43–5, '13; 58–60, '18; 73–5, '23; 76, '24. Afterward continued as Poggendorff's Annalen (q. v.).

J. d. M. Journal des Mines. 8vo, Paris. In monthly nos. 2 v. ann.; 1, 2, 1797; 11, 12, 1802: 21, 22, '07; 31, 32, '12; 37, 38, '15. Continued after in Annales des Mines (q. v.).

J. de Phys. Journal de Physique. 4to, Paris, 2 vols. ann. Edited by Abbé Rozier (and hence called Rozier's J.), for vols. 1–43 (for a time with also Mongez, Jr.); by Delametherie for vols. 44–84; and afterward by Blainville. Two introductory vols., 1771, 1772; vols. 1, 2, 1773; 11, 12, '78; 22, 23, '83; 32, 33, '88; 42, 43, '93; 44, 45, '94 (French Revolution); 46, 47, '98; 56, 57, 1803; 66, 67, '08; 76, 77, '13; 86, 87, '18; 94, 95, '22; 96, 1823.

J. pr. Ch. Journal für praktische Chemie. 8vo, Leipzig, 3 vols. ann. Begun in 1834; first edited by Erdmann & Schweigger-Seidel (see Schweigger J.); from 1838 by E. & Marchand; from 1852, by E. & Werther. Vols. 1–3, 1834; 19–21, '40; 34–36, '45; 49–51, '50; 64–66, '55; 79–81, '60; 94–96, '65; 109–111, '70. Preceded by J. f. pr. und Œkonomische Chemie, 18 vols. 8vo, 3 vols. ann., begun in 1828.

Jahrb. Min. Jahrbuch für Mineralogie, Geognosie, Geologie, und Petrefaktenkunde: edited by K. C. v. Leonhard & H. G. Bronn. 8vo, Heidelberg, 1 vol. ann. 1830–32, 4 Nos. a year; after '32, 6 Nos., and called Neues Jahrbuch etc. Vol. 1, 1830; 6, '35; 11, '40; 16, '45; 21, '50; 26, '55; 31, '60; 36, '65; 41, '70.

Arsb. } Arsberättelser om framstegen i Kemi och Mineralogi, af Jac. Berzelius. In German,
Jahresb. } Jahresbericht über die Fortschritte der Chemie und Mineralogie. 8vo; usually designated by the year. Commenced with 1821. Vol. 1, 1821; 11, '31; 21, '41; 30, 1850; the last three vols by Svanberg. Continued in the Giessen Jahresbericht, issued by Liebig & Kopp, from 1847 to '56; by F. Zamminer, '57; Kopp & Will, in '58; and Will alone from '63 on. The first vol. covers the years 1847, '48.

Karst. Arch. Min. Archiv für Mineralogie, Geognosie, Bergbau und Hüttenkunde. 26 vols. 8vo, 1829–1855, Berlin. Edited for vols. 1–10 by C. J. B. Karsten; later by Karsten & v. Dechen.

Kastn. Arch. Nat. Archiv. für die gesammte Naturlehre; edited by K. W. G. Kastner. 8vo, Nuremberg. 27 vols., 3 vols. ann., 1824–'35.

Kell. & Tiedm. Nordamerikanischer Monatsbericht für Natur- und Heilkunde; edited by Dr W. Keller & Dr. H. Tiedemann. 4 vols., 8vo, Philadelphia. Vol. 1, 1850; 2, 3, '51 4, '52.

Lempe's Mag. Magazin für die Bergbaukunde, by J. F. Lempe. Dresden, vols., 8vo, 1, 1785 2, 3, '86; 4, '87; then 1 vol. ann. till 11, '94; 12, '98; 13, '99.

L'Institut. L'Institut, a weekly journal in small fol., Paris, 1 vol. ann.; begun in 1832. 36th year or vol. in 1868.

Mag. Nat. Helvet. Magazin für die Naturkunde Helvetiens; herausg. A. Höpfner, Zurich Begun in 1787.

Moll's Efem. Efemeriden der Berg- und Hüttenkunde; edited by C. E. von Moll. 5 vols.; 1, 1805, at München; afterward at Nürnberg, 2, '06; 3, '07; 4, '08; 5, '09. Preceded by v. Moll's Jahrb. f. B. H., Salzburg, 5 vols., 1797–1801; and Annalen id., Salzburg, 3 vols. 1802–'04.

Nicholson's J. Journal of Natural Philosophy, Chemistry, and the Arts; by Wm. Nicholson London, 1st ser., 5 vols., 4to, vol. 1, 1797; 5, 1801. 2d ser., 36 vols. 8vo, vol. 1, 1802 36, 1813.

Nyt Mag. Nyt Magazin for Naturvidenskaberne; by C. Langberg. 8vo, Christiania.

Phil. Mag. Philosophical Magazine. 8vo, London. 1st ser. by Tilloch, 2 or 3 vols. a year; 1 2, 1798; 3–5, '99; 6–8, 1800; 21–23, '05; 30–32, '08; 33, 34, '09 (thence 2 v. ann.); 35-36, '10; 45, 46, '15; 55, 56, '20; 65, 66, '25; 67, 68, '26. 2d ser., or Philosophical Magazine and Annals of Philosophy, 2 v. ann.; 1, 2, 1827; 11, '32. 3d ser., London & Edinburgh Phil. Mag.; 1, 1832; 2, 3, '33; 12, 13, '38; 22, 23, '43; 32, 33, '48; 36, 37, '50. 4th ser., L., E. & Dublin Phil. Mag., 1, 2, 1851; 11, 12, '56; 21, 22, '61; 31, 32, '66.

Pogg. or **Pogg. Ann.** Annalen der Physik und Chemie; edited by J. C. Poggendorff. 8vo, Leipzig, 3 vols. ann. Preceded by Gilbert's Annalen (q. v.). Vols. 1, 2, 1824; 3–5, '25; 18–20, '30; 27–29, '33; 30, Index vol.; 31–33, '34; 34–36, '35; 49–51, '40; 63–66, '45; 79–81, '50; 94–96, '55; 109–111, '60; 124–126, '65; 139–141, '70.

Q. J. Sci. Brandes' Quarterly Journal of Science. 8vo, 2 vols. ann. after 1819. Published by the Royal Institution. Vol. 1, 1816; 2, 3, '17, '17–'18; 4, 5, '18; 6, 7, 8, '19; 9, 10, '20; 19. 20, '25; 27, 28, '29.

Rec. Gen. Sci. Records of General Science; by Thos. Thomson. 4 vols., 8vo, Edinburgh. Vols. 1, 2, 1835; 3, 4, '36.

Revista Minera. Revista Minera, Periodico cientifico é industrial redactado por una Sociedad de Ingenieros. 2 vols., 8vo, Madrid. Vol. 1, 1850; 2, '51.

Scherer's J. Allgemeines Journal der Chemie; conducted by A. N. Scherer. 10 vols., Leipzig und Berlin; 1, 1798; 2, 3, 1799; 6, 7, 1801; 10, '03. Continued as Gehlen's Journal (q. v.).

Schweigg. J. Journal für Chemie und Physik; conducted by J. S. C. Schweigger. Nürnberg, 8vo. Also under the title Jahrbuch der Chemie und Physik. 3 vols. a year; 1–3, 1811; 16–18, '16; 28–30, '20; afterward issued by Schweigger & Meinecke; then by J. S. C. Schweigger & Fr. W. Schweigger-Seidel; then by Fr. W. Schweigger-Seidel; 31–33, 1821; 46–48, '26; 61–63, '31; 67–69, '33. The next year began the J. pr. Ch. (q. v.), by Erdmann & Schweigger-Seidel.

Tasch. Min. Taschenbuch für die gesammte Mineralogie, von C. C. Leonhard. 18 vols., 12mo, Frankfurt a. M., 1 vol. ann. Vol. 1, 1807; 4, '10; 9, '15; 14, '20;- 18, '24.

2. *Transactions, etc., of Scientific Societies.*

Abh. Ak. Berlin. Abhandlungen der königlichen Preuss. Akademie der Wissenschaften zu Berlin. 4to, Berlin. Vol. 1 (for 1804–1811) issued in 1815.

Abhandl. Senk. Ges. Frankfurt. Abhandlungen von d. Senkenbergischen naturforschenden Gesellschaft zu Frankfurt. Begun in 1854. Vol. vii. in 1868.

Ak. H. Stockholm. K. Vet.-Academinens Handlingar, Stockholm.

Amer. Assoc. Proceedings of the American Association for the Advancement of Science. 8vo. Vol. 1, meeting at Philadelphia in 1848; 2, at Cambridge in '49; 3, at Charleston in '50; 4, at N. Haven, '50; 5, at Cincinnati, '51; 6, at Albany, '51; 7, at Cleveland, '53; 8, at Washington, '54; 9, at Providence, '55; 10, at Albany, '56; 11, at Montreal, '57; 12, at Baltimore, '58; 13, at Springfield, '59; 14, at Newport, '60; 15, at Buffalo, '66; 16, at Burlington, '67.

Ann. Lyc. N. Hist. N.Y. Annals of the Lyceum of Natural History of New York. Begun in 1824. Vol. 8 unfinished in 1868.

Anzeig. Ak. Wien. Anzeiger der K. K. Akad. d. Wissenschaften. 8vo, Wien. Begun in 1864. 1 vol. ann.

Ber. Ak. München. Sitzungsberichte der K. bayerischen Akad. der Wiss. zu München (Munich) 8vo.

Ber. Ak. Wien. Sitzungsberichte der K. K. Akad. der Wiss., Wien (Vienna). Commenced in 1848, 8vo.

Ber. Ak. Berlin. Monatsberichte der. K. Preuss. Akad. der Wissenschaften zu Berlin. 8vo Begun in 1836.

[illegible] Beobachtungen und Entdeckungen, etc.). Next, Neue Schriften.
[illegible] '99; 3, 1801; 4, 1803–4. Afterward Magazin, etc. (q. v.).
[illegible] Schriften der russisch-kaiserlichen Gesellschaft für die gesammte
[illegible] continuation see Verh.
[illegible] Scientiarum Fennicæ, Christiania, Norway.
[illegible] Philad. Transactions of the American Philosophical Society. 4to

[illegible] Transactions of the Royal Society of Edinburgh. 4to.

Verh. Min. Ges. St. Pet. Verhandlungen d. russisch-kaiserlichen mineralogischen Gesellschaft zu St. Petersburg.

Verh. nat. Ges. Basel. Verhandlungen der naturforschenden Gesellschaft in Basel. Begun in 1854

Verh. nat. Ver. Bonn. Verhandlungen des naturhistorischen Vereines der preuss. Rhein lande und Westphalens. Begun in 1844.

ZS. G., or ZS. G. Ges. Zeitschrift der deutschen geol. Gesellschaft. 8vo, Berlin; a quarterly; 1 vol. ann.; vol. 1. 1849; 11, '59; 21, '69.

ZS. Nat. Ver. Halle. Zeitschrift für die gesammten Naturwissenschaften, von dem nat. Verein f. Sachsen und Thüringen in Halle. Begun in 1853.

3. *Independent Works.*

Agric., Ort. Caus. Subt. Georgius Agricola, de Ortu et Causis subterraneorum; preface dated 1543.

Agric., Foss. Id., de natura fossilium; pref. dated 1546; and De veteribus et novis metallis: pref., 1546.

Agric., Berm. Bermannus, sive De re metallica Diallogus; pref., 1529.

Agric., Interpr. Interpretatio Germanica vocum rei metallicæ; pref., 1546. The edition of Agricola's works, cited beyond, including the four preceding parts, is one in folio, 1 vol., Basileæ (Basle), 1558.

Agric., Metall. De re Metallica; by id. Preface dated 1550. Fol., Basileæ, 1557.

Aikin, Min. Manual of Mineralogy; by A. Aikin. 2d ed., 8vo, London, 1815. The 1st ed appeared in 1814.

Albert. Magnus, Min. Albertus Magnus, De Mineralibus. Written after 1262.

Alger, Min. Treatise on Min. by Wm. Phillips; 5th ed. by R. Allan, with numerous additions, by F. Alger. 8vo, Boston, 1844.

Allan, Min. Manual of Mineralogy; by R. Allan. 8vo, Edinburgh, 1834. See also PHILLIPS

Allan, Min. Nomencl. Mineralogical Nomenclature; by T. Allan. 8vo, Edinburgh, 1814.

Argenville, Oryct. L'Histoire Naturelle, etc.; by D. d'Argenville. 4to, Paris, 1755.

Arppe, Finsk. Min. Analyser af Finska Mineralier; by A. E. Arppe. Part I., 1855, from the Act. Soc. Fenn., iv. 561–578; II., 1857, ib., v. 467 (paged 1–51); III., 1859–1861, ib. vi 580.

Aristotle. Aristotle's works; particularly the Μετεωρολογικά, or "Meteorology," and Περὶ Θαυμασίων ἀκουσμάτων, or "Wonderful Things Heard of." Works written about the middle of the 4th century B.C. A. born about 384 B.C. and d. 322 B.C.

B. de Boot. Lap. Gemmarum et Lapidum Historia. 4to, Jena, 1647; the 1st edit. published at Jena in 1609; the 2d, enlarged by A. Toll, Lugduni Bat., 8vo, 1636.

Beck, Min. N. Y. See Rep. Min. N. Y., beyond.

Beud., Tr., 1824, 1832. Traité élémentaire de Min.; by F. S. Beudant. 8vo, Paris, 1824; 2d ed., 2 vols., 1832.

Bergm., Opusc. Opuscula of Torbernus Bergmann. 1780.

Bergm., Sciagr. Sciagraphia Regni Mineralis (in Latin); by T. Bergmann. 8vo, 1782; reprint in London, 1783.

BERZ N. SYST. MIN. Neues System der Mineralogie; translated from the Swedish by Drs. Gmelin and Pfaff. Nürnberg, 1816.

Berz. N. Syst. Min. Nouveau Système de Minéralogie; by J. J. Berzelius. 8vo, Paris, 1819; translated from the Swedish.

Berz. Lothr. Die Anwendung des Löthrohrs, etc. Germ. Transl. by H. Rose. Nürnberg, 1821; 4th ed., 1844. American ed. by Whitney, 1845.

BLUMENBACH HANDB. Handbuch der Naturgeschichte. 8vo, 8th ed., Göttingen, 1807.

Born, Brief. Walschl. Briefe aus Wälschland (Italy); by I. v. Born. 8vo, Prague, 1773.

Born, Lithoph. Lythophylacium Bornianum; Index Fossilium quæ colligit, etc., Ignatius S. R I. Eques a Born. 2 parts, Prague; part 1, 1772; 2, '75. A descriptive catalogue, but without notes.

Born, Cat. Foss. de Raab. Catalogue méthodique et raisonné de la collection des Fossiles de Mlle. Eleonore de Raab; by id. 4 vols., 8vo, Vienna, 1790.

BOURN. CAT. Catalogue de la Collection minéralogique particulière du Roi; by Comte de Bournon. 8vo, mit Atlas in fol., Paris, 1817.

Bourn. Min. Traité de Mineralogie; by Comte de Bournon. 3 vols., 4to, 1808.

Breith., Char. 1820. Kurze Charakteristik des Mineral-Systems; by A. Breithaupt. 8vo, Freiberg, 1820.

Breith., Char. 1823, 1832. Vollständige Char., etc.; by id. 8vo, Dresden, 1823; 2d ed. 1832.

Breith., Uib. 1830. Uibersicht des Mineral-System's; by A. Breithaupt 8vo, Freiberg, 1830

Breith., Handb. Vollständiges Handbuch der Mineralogie; by id. 8vo, Dresden and Leipzig vol. 1, introduct., 1836; 2, '41; 3, '47.

Brochant, Min. Traité de Minéralogie; by A. J. M. Brochant. Paris, 1808; an earlier edition in 1800.

Bromell, Min. Herr Magni von Bromells Mineralogia. 2d ed., 16mo, Stockholm, 1739. 1st ed. pub'd in 1730.

Brongn., Min. Traité élémentaire de Minéralogie; by A. Brongniart. 2 vols., 8vo, Paris, 1807.

Brongn., Tabl. Tableau des Espèces Minérales; by id. 48 pp., 8vo, Paris, 1833.

Brooke, Cryst. Familiar Introduction to Crystallography; by J. Brooke. 8vo, London, 1823.

B. & M., Min. Introduction to Mineralogy, by the late Wm. Phillips; new edition, with extensive alterations and additions, by H. J. Brooke and W. H. Miller. 8vo, London, 1852. Prof. Miller is the author also of a Treatise on Crystallography, 8vo, Cambridge, 1839, giving the elements of the system adopted in the above work, a system first proposed by Whewell, in Phil. Trans. for 1825.

Brückmann, Magnalia Dei in locis subterraneis. 2 parts, fol.; part 1, 1727; 2, '30.

Cæsius, Min. De Mineralibus; by Bernardius Cæsius. 656 pp., fol., Lugduni, 1636.

CAPPELLER, CRIST. Prodromus Cristallographiæ; Marc. Ant. Cappeller. 4to, Lucerne, 1723.

Cat. de Drée. Catalogue des huit Collections qui composent le Musée mineralogique de Et. de Drée. 4to, Paris, 1811. Dufrénoy speaks of it as the work of M. Leman.

Chapman, Min. Practical Mineralogy; by E. J. Chapman. 8vo, London, 1843.

Chapman, Char. Min. Brief Description of the Characters of Minerals; by id. 12mo, London, 1844.

Cleaveland, Min., 1816, 1822. Treatise on Mineralogy and Geology. 8vo, Boston, 1816; 2d ed., 2 vols., 8vo, Boston, 1822.

Cronst., or Cronst. Min., 1758, 1781. Mineralogie, eller Mineral-Rikets Upstallning; by A. Cronstedt (but issued anonymously). 12mo, Stockholm, 1758; Brünnich's edit. in Danish, Copenhagen, 8vo, 1770; 2d Swedish ed., Stockholm, 1781; Magellan's edit. in English, 2 vols., 8vo, London, 1788.

Dana, Min. Boston. Outlines of the Mineralogy and Geology of Boston and its vicinity; by J Freeman & S. L. Dana. 8vo, Boston, 1818.

Dana, Min. This work. Editions of 1837, 1844, 1850, 1854. Supplements 1 to 10 to last edition in the Am. J. Sci., 1855-1862, the last three by G. J. Brush.

Daubenton, Tabl. Tableaux méthodique des Minéraux. Paris, 1784. Only a classified catalogue. Several subsequent editions were issued, the 6th in 1799.

Davila, Cab. Catalogue syst. et raisonné des Curiosités de la Nature et de l'Art qui composent le Cabinet de M. Davila. 3 vols., 8vo, Paris, 1767.

Delameth., Sciagr. New edition of Mongez's Sciagraphie (Fr. trl. of Bergmann's Sciagr., with additions); by J. C. Delamétherie. 2 vols., 8vo, Paris, 1792.

Delameth., T. T. Théorie de la Terre; by id. 2d ed., 5 vols., Paris, 1797; vols. 1, 2, of this edition contain his Mineralogy.

Delameth., Min. Leçons de Minéralogie; by id. 8vo, vol. 1, 1811; 2, '12, Paris.

DE LISLE, CRIST., 1772. Essai de Cristallographie; by Romé de l'Isle. 8vo, Paris, 1772.

De Lisle, Crist., 1783. Cristallographie, ou Description des formes propres à tous les corps du Regne minéral; by id. Called 2d edition of the preceding. 4 vols., 8vo, Paris, 1783.

Demeste Lettres. Lettres sur la Minéralogie; by Dr. Demeste. 2 vols., 16mo, 1779.

Descl., Min. Manuel de Minéralogie; by A. DesCloizeaux. 8vo, Paris, vol. 1, 1862.

Descl. Quartz. Mémoire sur la Cristallisation et la Structure intérieure du Quartz; by A. Descloizeaux. 212 pp., 4to, with 5 folded plates, Paris, 1858.

Dioscor. Dioscorides περί ὕλης ἰατρικῆς (Materia Medica), written about A.D. 50. In the mineral part treats especially of the medical virtues of minerals, but often gives also short descriptions. Not alluded to among the many references in Pliny, but evidently cited from.

Domeyko, Min., 1845, 1860. Elementos de Mineralogia; by I. Domeyko. 8vo, Chili, 1st ed., Serena, 1845; 2d ed., Santiago, 1860.

Domeyko, Tratado de Ensayes; by id. 2d ed., 8vo, Valparaiso, 1858.

Dufr., Min., 1844, 1856–1860. Traité de Minéralogie; by A. Dufrénoy. 4 vols., 8vo (the last of plates), Paris, 1844; 2d ed., 5 vols.; 1, 2, 3, '56; 4, '59; 5, '60.

Emmerling, Min. Lehrbuch der Mineralogie; by L. A. Emmerling. 8vo, Giessen, 1st ed. 1793-'97; 2d ed., '99, 1802.

Ercker, Aula Subt. Aula Subterranea (on Ores, Mining, and Metallurgy); by L. Ercker Written in 1574, published in 1595.

Erdmann, Min. Lärobok i Mineralogien; by A. Erdmann. 8vo, Stockh., 1853.

Erdmann, Dannemora Jernm. Dannemora Jernmalmsfält, etc.; by A. Erdmann. 12mo Stockholm, 1851. Also Utö Jernm., 1856.

Estner, Min. Versuch einer Mineralogie. 3 vols. in 5 parts, 8vo, Wien, 1794–1804.

Estner, über Werner's Verbess. in Min. Freymüthige Gedanken über Herrn Inspector Werner's Verbesserungen in der Mineralogie, nebst einigen Bemerkungen über Herrn Assessor Karstens Beschreibung des vom sel. Leske Mineralien-Cabinetts; by Abbé Estner. 64 pp., 18mo, Wien, 1790.

Fabricius, Met. De rebus metallicis ac nominibus observationes variæ, etc., ex schedis Georgii Fabricii. Tiguri, 1566. Issued with an edition of Gesner's Foss.

Faujas, Volc. Viv. Recherches sur les Volcans éteints du Vivarais et du Velay; by Faujas de St. Fond. Fol., Grenoble et Paris, 1778. By the same, Minéralogie des Volcans, 8vo, Paris, 1784.

Fors., Min. Minerographia; by Sigfrid Avon Forsius. 16mo, Stockholm, 1643.

Gallitzin, Dict. Min. Recueil de noms par order alphabétique apropriés en Mineralogie; by D de Gallitzin. Sm. 4to, Brunswick, 1801.

Gesner, Foss. De omni rerum fossilium genere, Gemmis, Lapidibus, Metallis, etc.; opera Conradi Gesneri. Tiguri, 1565.

Glocker, Handb., 1831, 1839. Handbuch der Mineralogie; by E. F. Glocker. 8vo, Nürnberg, 1831; 2d edit., 1839.

Glocker, Syn. Generum et Specierum Mineralium secundum Ordines Naturales digestorum Synopsis; by id. 8vo, Halle, 1847.

GMELIN, MIN. Einleitung in die Mineralogie; by J. F. Gmelin. 8vo, Nürnberg, 1780. By the same, Grundriss einer Min. 8vo, Göttingen, 1790.

Greg & Lettsom, Min. Manual of the Mineralogy of Great Britain and Ireland; by R. P. Greg and W. G. Lettsom. 8vo, London, 1858.

Gurlt, Kunstl. Min. Uebersicht der pyrogenneten künstlichen Mineralien, namentlich der krystallisirten Hüttenerzeugnisse; by Dr. A. Gurlt. 8vo, Freiberg, 1857.

H., Tr., 1801, 1822. Traité de Minéralogie; by C. Haüy. A 4to ed. of 4 vols., with atlas in fol.; also an 8vo ed., Paris: 1801; 2d ed., 4 vols., 8vo, with fol. atlas, 1822.

H., Crist. Haüy Traité de Cristallographie; by id. 2 vols., 8vo, in 1822.

H., TABL. COMP. Tableau Comparatif des résultats de la Cristallographie et de l'analyse chimique relativement à la classification des Minéraux; by id. 8vo, Paris, 1809.

Haid., Min. Mohs. Treatise on Mineralogy, by F. Mohs; trl., with considerable additions, by Wm. Haidinger. 3 vols., 8vo, Edinburgh, 1825.

Haid., Min. Anfangsgründe d. Min.; by id. 8vo, Leipz., 1829.

Haid., Handb. Handbuch d. bestimmenden Mineralogie; by id. 8vo, Wien, 1845.

Haid., Ueb. Uebersicht der Resultate Mineralogischer Forschungen im Jahre 1843: by id. Erlangen, 1845.

Hausm., Versuch. Versuch eines Entwurfs zu eines Einleitung in die Oryktognosie; by J. F. L. Hausmann. 8vo, Braunschweig, 1805; Cassel, '09.

Hausm., Handb., 1813, 1847. Handbuch der Mineralogie; by id. 3 vols., 12mo, Göttingen, 1813; 2d ed., 1st vol., introductory, '28; 2d, in two parts, '47.

Henckel, Pyrit. Pyritologia, oder Kiess-Historie; by J. Fr. Henckel (of Saxony). 8vo, Leipzig, 1725.

Hessenberg, Min. Not. Mineralogische Notizen; by Fr. Hessenberg. 4to, with plates, Nos. 1–8, 1854–'68. (From the Abhandl. d. senkenbergischen naturforschenden Gesellschaft in Frankfurt a. M., vols. ii to vii.) No. 7 contains an index to the first seven.

HIAERNE, ANLEDN. Kort Anledning til äskällige Malm och Bergarters, Mineraliers, etc.; by Urban Hiaerne. Stockholm, 1694.

His., Min. Geogr. Swed. Mineralogisk Geografi öfver Sverige; by W. af. Hisinger. 8vo, Stockholm, 1808. **Also**

His. Min. Geogr. Wöhler. Versuch einer mineralogischen Geographie von Schweden, übersetzt von F. Wöhler. 8vo, Liepzig, 1826.

His. Handbok. Handbok för Mineraloger under Resor i Sverige; by W. Hisinger. 8vo, Stockholm, 1843.

Hill, Foss. Fossils arranged according to their obvious characters; by John Hill. 8vo, London, 1771. (De Lisle says it was not issued till 1772.)

Hoff, Mag. Magazin für die gesammte Min., etc.; by K. E. A. v. Hoff. 1 vol., 8vo, Leipzig, 1801.

Hofmann, Min. Handb. d. Mineralogie; by C. A. S. Hofmann. 4 vols., 8vo, Freiberg. Vol. 1, 1811; 2, part *a*, '12, *b*, '15; 3, parts *a*, *b*, '16; 4, part *a*, '17, *b*, '18. Work, after 2d vol., part *a*, issued by Breithaupt, Hofmann having died March, 1813. Vol. 4, part *b*, consists of notes and additions by Breithaupt, and includes also the Letztes Min. Syst. of Werner (1817).

Huot, Min. Manuel de Minéralogie; by J. J. N. Huot. 2 vols., 16mo, Paris, 1841.

Jameson, Min., 1804, 1816, 1820. A System of Mineralogy; by R. Jameson. 8vo, Edinburgh; 1st ed., 2 vols., 1804; 2d, 3 vols., '16; 3d, 3 vols., 1820.

Published also a Manual of Min., 8vo, in 1831; and Mineralogy according to the Natural System (from Encycl. Brit.), in 1837. Also, in 1805, a Treatise on the External Characters of Minerals 8vo, Edinburgh.

Jasche, Kl. Schrift. Kleine min. Schriften; by C. F. Jasche. 12mo, Sondershausen, 1817.

John, Untersuch. Chemische Untersuchungen mineralischer, etc., Substanzen; by J. Fr. John 8vo, Berlin, Fortsetzung d. chem. Laboratoriums, Berlin, which makes vol. 1 of series vol. 2, 1810; 3, 1813; 4, 1816; 6, 1821.

Karsten, Mus. Lesk. Museum Leskeanum, Regnum minerale; by D. L. G. Karsten. 2 vols, 8vo Leipzig, 1789.

Karst., Tab., 1791. Tabellarische Uebersicht der mineralogisch-einfachen Fossilien; by id. Fol., Berlin, 1791.

Karst., Tab., 1800, 1808. Mineralogische Tabellen; by id. Fol., Berlin, 1800; 2d ed., fol., Berlin, 1808.

Karst., Wern. Verbess. Min. Ueber Herrn Werners Verbesserungen in der Mineralogie auf Veranlassung der freimüthigen Gedanken, etc., des Herrn Abbé Estner; by id. 80 pp. 12mo, Berlin, 1793.

Kenng., Ueb. Uebersichte der Resultate mineralogischer Forschungen; by G. Ad. Kenngott. For the years 1844–'49, Wien, 1852; for years 1850–'51, Wien, 1853; for '54, Wien, 1854; for '53, Liepzig, 1855; for '54, ib., 1856; for '55, ib., 1856; for '56, '57, ib., 1858; for '58, ib., 1860; for '59, ib., 1860; for '60, ib., 1862; for '61, ib., 1862; for '62–'65, ib., 1868. [The last was received just as this volume was leaving the press.]

Kenng., Min., 1853. Das Mohs'sche Mineralsystem; by id. 8vo, Wien, 1853.

Kirwan, Min. Elements of Mineralogy; by R. Kirwan. 2 vols., 8vo, London, 2d edition, 1794. 1st ed. was issued in 1784, 8vo.

Klapr., Beitr. Beiträge zur chemischen Kenntniss d. Mineralkörpers; by M. H. Klaproth. 8vo, vol. 1, 1795; 2, '97; 3, 1802; 4, '07; 5, '10; 6, '15.

Kob., Char. Charakteristik d. Mineralien; by Fr. von Kobell. 8vo, Nürnberg, Abth. 1, 1830; 2, 1831.

Kob., Min. Grundzüge d. Mineralogie; by id. 8vo, Nürnberg, 1838.

Kob., Taf., 1853. Tafeln zur Bestimmung d. Mineralien; by id. 5th ed., München, 1853. The 8th edit. appeared in 1864.

Kob. Min.-Namen. Die Mineral Namen; by id. 8vo, München, 1853.

Kob., Gesch. Min. Geschichte d. Min.; by id. 8vo, München, 1864.

Koksch., Min. Russl. Materialen zur Mineralogie Russlands; by N. v. Kokscharof. 8vo, St. Petersburg, vol. 1, 1853, '54; 2, '54–'57; 3, '58; 4, '61–'66; 5, still incomplete. Also by same author, Vorlesungen über Mineralogie. Vol. 1, 4to, St. Petersburg, 1865.

Kopp, Gesch. Ch. Geschichte d. Chemie; by H. Kopp. 4 parts, 8vo, Braunschweig, 1843–'47.

KRONSTEDT. See Cronstedt.

Lampadius, Samml. Sammlung practisch-chemischer Abhandlungen; by W. A. Lampadius. 3 vols., 8vo, Dresden; vol. 1, 1795; 2, 1797; 3, 1800.

Lenz, Min. Versuch einer vollständigen Anleitung zur Kenntniss der Mineralien; by D. G. J. Lenz. 2 vols., 8vo, Leipzig, 1794. By the same, Tabellen, 1781; Handbuch, 1791; Grundriss, 1793; Mustertafeln, 1794; Tabellen, fol., 1806; System, 1800, 1809; Handbuch, 1822.

Leonh., Syst.-Tab. Systematisch-tabellarische Uebersicht und Char. d. Mineralkörper; by C. C Leonhard, K. F. Merz. and J. H. Kopp. Fol., Frankfurt a. M., 1806.

Leonh., Orykt. Handbuch der Oryktogonosie; by K. C. Leonhard. 8vo, Heidelberg, 1821. Also 2d ed., 8vo, Heidelberg, 1826.

Leonh., topogr. Min. Handwörterbuch d. topographischen Mineralogie; by G. Leonhard. Heidelberg, 1843.

Levy's Heuland. Description d'une collection de Minéraux, formée par M. Henri Heuland, et appartenant à M. Ch. H. Turner, de Rooksnest, dans le comté de Surrey en Angleterre; by A. Levy. 3 vols., 8vo, with an atlas of 83 pl., London, 1837.

Libavius, Alchem. Alchemia, A. Libaviæ. Frankfurt, 1597.

LINN., SYST. NAT. Systema Naturæ of Linnæus. 1st edit., 1735; 10th ed., T. 3, 1770.

Lucas, Tabl. Tableau méthodique des Espèces Mineraux; by J. A. H. Lucas. Part 1, 8vo, 1806; 2, 1813, Paris. The first part contains brief descriptions taken from Haüy's work, and also from his subsequent lectures and published announcements of his courses. The second includes in the main Haüy's Tabl., with many additional notes.

Ludwig's Min, or Ludwig's Wern. Handbuch d. Mineralogie nach A. G. Werner; by C. F. Ludwig. 2 vols., 8vo, Leipzig, 1803, '04.

Marx, Crystallkunde. Geschichte der Crystallkunde; by Dr. C. M. Marx. 8vo, Carlsruhe and Baden, 1825.

Matthesius, Sarepta. Berg Postilla, oder Sarepta; by J. Matthesius. Fol., Nürnberg, 1562.

Mohs, Null Kab. Des Herrn J. F. Null Mineralien-Kabinet, nach einem, durchaus auf äussere Kennzeichen gegründeten Systeme geordnet; by F. Mohs. 3 Abthl., 8vo, Wien, 1804.

Mohs, Char. Characteristic of the Natural History System of Mineralogy; by id. 8vo, Edinburgh, 1820.

Mohs, Min., 1822. Grund-Riss der Mineralogie; by id. 8vo, vols. 1, 2, 1822, '24, Dresden (Translated into English by W. Haidinger. See HAID.)

Mohs, Min., 1839. Anfangsgründe der Naturgeschichte des Mineralreichs; by F. Mohs Zweiter Theil bearbeitet von F. X. M. Xippè; 8vo, Wien, 1839 (Erster Theil, introductory, published in 1836). A first edition of this work in 1832.

Mont. & Cov., Min. Prodromo della Mineralogia Vesuviana; vol. 1, Orittognosia. 8vo, Napoli, 1825.

NAPIONE, MIN. Elementi di Mineralogia: by Napione. 8vo, Turin, 1779.

Naumann, Kryst. Lehrbuch der Krystallographie; by C. F. Naumann. 2 vols., 8vo, with numerous figs., Leipzig, 1829. Naumann has since published the smaller works, Anfangsgründe der Kryst., 8vo, 1854; Elemente der Theoretischen Kryst., 8vo, 1856.

Naumann, Min. Elemente der Mineralogie. 8vo, Liepzig, 1st ed., 1846; 2d., 50; 3d ed., '52; 4th, '55; 5th, '59; 6th, '64. Naumann published Lehrbuch der Min., 8vo, Berlin 1828.

NECKER MIN. Le regne minéral ramené aux méthodes de l'histoire naturelle; by L. A. Necker 2 vols., 8vo, Paris, 1836.

Nicol, Min. Manual of Mineralogy; by J. Nicol. 8vo, Edinb., 1849.

Nöggerath, Min. Stud. Geb. Nederrhein. Mineralogische Studien über die Gebirge am Niederrhein; by J. J. Nöggerath. 8vo, Frankfurt a. M., 1808.

A. E. Nordensk., Finl. Min. Beskrifning öfver de i Finland funna Mineralier; by A. E. Nordenskiöld. 8vo, Helsingfors, 1855. **Also** 2d ed., ib., 1863.

N. Nordensk., Finl. Min. Bidrag till närmare Kännedom af Finlands Mineralier och Geognosie; by Nils Nordenskiöld. 8vo, Stockholm, 1820.

N. NORDENSK VERZ. Verzeichn. d. in Finland gef. Min.; by id. Helsingfors, 1852.

Plattner, Probirk. Die Probirkunst mit dem Löthrohr; by C. F. Plattner. Last ed. by T. Richter, 8vo, 1865.

Plin. Historia Naturalis C. Plinii Secundi. First published A.D. 77. Latin ed. consulted, Sillig's, in 8 vols., 1851–'58; and English, that of Bostock & Riley, 5 vols., 12mo, London, 1855. Pliny's Natural History is divided into xxxvii Books; and these into short chapters. The numbering of the chapters differs somewhat in different editions; that stated in the references is from the English edition. The last five books are those that particularly treat of metals, ores, stones, and gems.

Phillips, Min., 1823, 1837. Elementary Introduction to Mineralogy. 8vo, 3d ed., London, 1823. 4th ed. by R. Allan, 8vo, 1837. The 1st ed. appeared in 1816; and this was republished in New York, in 1818. For Alger's Phillips, see Alger.

Quenstedt, Min. Handbuch der Mineralogie; by F. A. Quenstedt. 8vo, Tübingen, 1858. **Also** 2d ed., ib., 1863.

Ramm., Handw. Handwörterbuch des chemischen Theils der Mineralogie; by C. F. Rammelsberg. 8vo, Berlin, 1841. Supplement 1, '43; 2, '45; 3, '47; 4, '49; 5, '53.

Ramm., Min. J. J. Berzelius's neues chemisches Mineralsystem; by id. 8vo, Nürnberg, 1847.

Ramm., Min. Ch. Handb. d. Mineralchemie; by id. 8vo, Leipzig, 1860.

Rashleigh, Brit. Min. Specimens of British Minerals selected from the cabinet of Philip Rashleigh (descriptions and colored plates). 4to, London. Part 1, 1797; 2, 1802.

Rep. G. Cal. Report on the Geology of California; by J. D. Whitney. Large 8vo, San Francisco, 1865.

Rep. G. Can. Annual Reports on the Progress of the Geological Survey of Canada; by Sir Wm. E. Logan. Containing reports on mineralogy by T. S. Hunt. 8vo, 1845–'59. In 1863 a General Report for the years 1843–'63.

Rep. G. Mass. Report on the Geology of Massachusetts; by E. Hitchcock. 1st Rep., 1833, 8vo; 2d ed., 1835. 2d Rep., 1841, 4to.

Rep. G. N. Y. Reports on the Geological Survey of New York. Annual Reports in 8vo, 1837–'41; final in 4to.

Rep. Min. N. Y. Report on the Mineralogy of the State of New York; by L. C. Bock. 4to, 1842.

Reuss, Min. Lehrbuch d. Mineralogie; by F. A. Reuss. 8vo, 1801–'05, Leipzig. Divided into parts, and the parts into vols. Pt. 1 and pt. 2, vol. 1, 1801; vol. 2, '02; vol. 3, 4, '03; 3d pt., vol. 1, 2, '05; 4th pt., including index, '06.

Rio, Orykt. Elementos de Oryktognosia, ó del Conocimiento de los Fósiles, dispuestos segun los principios de A. G. Wérner; by A. M. del Rio. 4to, Mexico, 1795.

RIO, MIN. Nuevo Sistema Minerale; by id. Mexico, 1827.

Rio, Tabl. Min. Tablas mineralogicas por D. L. G. Karsten; by A. M. del Rio. 4to, Mexico, 1804.

Robinson, Cat. Catalogue of American Minerals, with their Localities; by S. Robinson. 8vo Boston, 1825.

Rose, Reis. Ural. Reise nach dem Ural, dem Altai, und dem Kaspischen Meere; by Gustav Rose. 8vo, Berlin; vol. 1, 1837; 2, '42.

Rose, Kryst.-Ch. Min. Das Krystallo-chemischen Mineral-System; by G. Rose. 8vo, Leipzig, 1852.

Sage, Min. Elémens de Minéralogie docimastique; by B. G. Sage. 2d ed., 2 vols., 1777. 1st ed. appeared in 1772.

Saussure, Voy. Alpes. Voyages dans les Alpes, par H. B. Saussure. 4 vols., 4to. Vols. 1, 2, 1779, '80; 3, 4, '96.

Scacchi, Mem. Min. e Geol. Memorie mineralogiche e geologiche; by A. Scacchi. 8vo, Napoli, 1841.

Scacchi, Crist. Quadri Cristallografici, e Distribuzione sistematica dei minerale; by id. 8vo, Napoli, 1842.

Scacchi, Mem. Geol. Campania. Memorie geologiche sulla Campania; by id. 4to, Napoli, 1849. By the same, Memoria sulla Incendio Vesuviano, 1855. Napoli, 1855. Polisimmetria dei Cristalli. 4to, 1864.

Schrauf. Atlas Kryst. Atlas der Krystall-Formen des Mineralreichs; by Dr. A. Schrauf. 4to, 1 Lief., Wien, 1865.

Schumacher, Verz. Versuch eines Verzeichnisses der in den Dänisch-Nordischen Staaten sich findenden einfachen Mineralien. 4to, Copenhagen, 1801.

Schutz, Nordamer. Foss. Beschreibung einiger Nordamerikanischen Fossilien; by A. G. Schütz, of Freyberg. 16mo, Liepzig, 1791. Contains the first notice of *celestine*, a mineral named by Werner from Schütz's American specimens.

Sella, Min. Sarda. Studii sulla Mineralogia Sarda; by Quintino Sella. 4to, Turin, 1856.

Shep., Min., 1832–1835, 1844, 1852, 1857. Treatise on Mineralogy; by C. U. Shepard. 1st part, 1 vol., 12mo, New Haven, 1832; 2d part, 2 vols., New Haven, 1835. **Also**, 2d ed. (with only the 1st part revised), New Haven, 1844. **Also**, 3d ed., 8vo, New Haven, No. 1, 1852; No. 2, '57.

Shep., Min. Conn. Report on the Geological Survey of Connecticut; by id. 8vo, N. Haven, 1837.

Steffens, Handb. Handb. d. Oryktognosie; by H. Steffens. 3 vols., 18mo, Halle; vol. 1, 1811; 2, '15; 3, '19.

Stromeyer, Unt. Untersuchungen über die Mischung der Mineralkörper, etc.; by Fr. Stromeyer. 8vo, Göttingen, 1821.

Theophr. Theophrastus Περὶ λίθων (on Stones); written about 315 B.C. Only a portion of the whole work is extant, but sufficient to show that the author was precise in his knowledge of minerals and careful in the statement of facts. T. born about 371 B.C., and d. 286 B.C.

Thomson, Min., 1802, 1836. Outlines of Mineralogy, Geology, and Mineral Analysis; by T. Thomson. 2 vols., 8vo, London, 1836. A treatise on Mineralogy published also with preceding editions of his Chemistry, the earliest in 1802.

Ullmann, Syst.-tab. Ueb. Systematisch-tabellarische Uebersicht der min.-einfachen Fossilien; by J. C. Ullmann. Small 4to, Cassel and Marburg, 1814.

Volger, Studien, etc. Studien zur Entwicklungsgeschichte der Mineralien; by G. H. O. Volger. 8vo, Zürich, 1854. Other works: Entwickl. der Min. d. Talk-Glimmer Familie, 1855; Arragonit und Kalcit, 1855; Monographie des Borazites, Hannover, 1855; Epidot und Granat, Beobachtungen über das gegenseitige Verhältniss dieser Krystalle, Zürich, 1855; Krystallographie, Stuttgart, 1854.

Vogl's Joach. Gängverhältnisse und Mineralreichthum Joachimsthals; by J. Fl. Vogl. 8vo, Teplitz, 1857.

Wall., or **Wall., Min.** Mineralogia, eller Mineralriket; by J. G. Wallerius. 12mo, Stockholm 1747.

Wall., Fr. Trl. French edition of Wallerius's Min. of 1747. 2 vols., 8vo, Paris, 1753. Published anonymously.

Wall., Min., 1772, '75. Systema Mineralogicum. 8vo, Holmiæ, vol. 1, 1772; 2, '75.

Wall., Min., 1778. Syst. Min. 2 vols., 8vo, Vienna, 1778.

Waltersh., Vulk. Gest. Ueber die vulkanischen Gesteine in Sicilien und Island (Iceland), und ihre submarine Umbildung; by W. Sartorius v. Waltershausen. 8vo, Göttingen, 1853.

Watts Dict. Ch. Dictionary of Chemistry; by H. Watts. 4 vols., 1863, '64, '65, '66; a fifth yet to be issued.

Wern., Auss. Kennz. Foss. Von d. äusserlichen Kennzeichen d. Fossilien; by A. G. Werner 8vo, Leipzig, 1774.

Wern., Ueb. Cronst. Kronstedt's Versuch einer Min. übersetzt und vermehrt von A. G. Werner. Vol. 1, part 1. Leipzig, 1780.

Wern., Min.-Kab. Pabst. Verzeichniss des Mineralien Kabinets des Herrn K. E. Pabst von Ohain; by A. G. Werner. 2 vols., Freiberg, 1791, '93.

Wern., Letzt. Min. Syst. Letztes Mineral-System. 8vo, Freiberg & Wien, 1817. A Catalogue with notes. Werner or his scholars issued, from time to time, a tabular synopsis of his Mineral system revised to the time of publication, on folio sheets, or published them in other works. The earliest after that of Werner's Cronstedt was issued by Hofmann in Bergm. J., 1789, vol. 1, p. 369. Emmerling's Min., i. 1799, contains the synopsis of 1798, and Ludwig's Min. contains that of 1800 and 1803. Leonhard's Tasch., iii. 261, that of 1809.

Westrumb, Kl. Phys.-Ch. Abh. Kleine physikalisch-chemische Abhandlungen; by J. F. Westrumb. 8vo, Leipzig, vol. 1, 1785; 2, '87; 3, '88; 4, '89; Hannover, 5, 6, '93; 7, '95; 8, '97.

Withering, Trl. Bergm. Sciagr. Outlines of Mineralogy, trl. from the original of Bergmann; by Wm. Withering. 8vo, 1783 (Reprinted in vol. 2 of Mem. and Tracts of the late Dr. Withering, London, 1822).

Whitney, Lake Sup. Report on the Geology of the Lake Superior Land District; by J. W. Foster and J. D. Whitney. 8vo, Part 1, 1850; 2, '51.

Whitney, Met. Wealth. The Metallic Wealth of the United States, described and compared with that of other countries; by J. D. Whitney. 8vo, Philadelphia, 1854.

Whitney, Miss. Lead Region. Report of a Geological Survey of the Upper Mississippi Lead Region; by id. (Made by authority of the State of Wisconsin.) 8vo, 1862.

Whitney, Rep. G. Cal. See Rep. G. Cal.

Whitney, Berz. Blowpipe. Berzelius on the Blowpipe; translated by J. D. Whitney. 8vo, Boston, 1845.

WOODWARD, **Foss.** Fossils of all kinds digested into a Method suitable to their mutual Relation and Affinity. 8vo, London, 1728.

Zepharovich, Min. Lex. Mineralogisches Lexicon für das Kaiserthum Oesterreich; by V. R. v. Zepharovich. 8vo, Wien, 1859.

The works in the above catalogue which are most important for the study of the history of mineral species are the following, the order cited being that of time:

Theophrastus; Dioscorides; Pliny's Natural History; Agricola's works; Linnæus's Systema Naturæ, 1st ed., 1735; Wallerius's Mineralogy in the original Swedish, 1747 (the first systematic, descriptive work, following in its system of classification mainly the 1st edition of Linnæus, which the author alludes to in his preface, among other Swedish works by Forsius, Hiærne, Bromell, and Swedenborg); Cronstedt's Mineralogy, 1757 (a new chemical system); Linnæus's Systema Naturæ, 10th ed., 1768; Romé de Lisle's Crystallographie, 1772, 1783 (the first systematic effort to apply the principles of crystallography to the science); Wallerius's Min. of 1772, 1778 (the system and facts are little changed from the earlier edition); Werner on the External Characters of Minerals, 1774, and his Cronstedt, 1780; Bergmann's Opuscula, 1780, and Sciagraphia, 1782; Hofmann's exposition of Werner's system in the Bergm. J., 1789; Emmerling's Mineralogy, 1793–'97, and 1799–1802; Lenz's Mineralogy, 1794; Klaproth's Beiträge, 1795–1810; Karsten's Tabellen, 1800; Haüy's Treatise on Mineralogy, 1801; Reuss's Mineralogy, 1801–1806; Ludwig's Werner, 1803, 1804; Mohs's Null Kab., 1804; Karsten's Tabellen, 1808; Lucas's Tableau, part 1, 1806 (giving views of Haüy of 1801 and 1801 to 1806); Brongniart's Mineralogy, 1807; Haüy's Tableau comparatif, 1809; Hausmann's Handbuch, 1813; Hoffmann's Mineralogie, 1811–1817; Ullmann's Uebersicht, 1814; Jameson's Mineralogy, 1816, 1820; Werner's Last Mineral System (Letztes, etc.), 1817; Cleaveland's Mineralogy, 1816, 1822; Berzelius's Nouv. Système, 1819; Leonhard's Handbuch, 1821, 1826; Mohs's Mineralogy, 1822; Haidinger's translation of Mohs, 1824; Breithaupt's Charakteristik, 1820, 1823, 1832; Beudant's Treatise, 1824, 1832; Phillips's Min., 1823, 1837; Glocker's Min., 1831, 1839; Shepard's Min., 1832–'35, and later editions; von Kobell's Grundzüge, 1838; Mohs's Min., 1839; Breithaupt's Min., 1836–1847; Haidinger's Handbuch, 1845; Hausmann's Handbuch, 1847; Dufrénoy's Min., 1844–1847 (also 1856–1859); Glocker's Synopsis, 1847; Brooke & Miller, 1852; von Kobell's Tafeln, 1853; Rammelsberg's Handwörterbuch and Supplements, 1841–1853; Kenngott's Uebersicht, 1844–1865 DesCloizeaux's Mineralogy, 1862; von Kobell's Geschichte, 1864.

7. Annotated Index to the Useful Metals and Metallic Ores.

GOLD.—*Native Gold* (1).[*] Distinguished from all minerals it resembles by its flattening under a hammer; its cutting like lead, although considerably harder; its resisting the action of nitric acid, hot or cold; its high specific gravity.

Gold also occurs in *Gold Amalgam* (11), *Sylvanite* (98), *Nagyagite* (99), *Petzite* (58A), and *Calaverite* (Supplement). Also sometimes in traces in Pyrite, Galenite, Chalcopyrite. Native Tellurium.

PLATINUM.—IRIDIUM.—PALLADIUM.—*Native Platinum* (3), the source of the platinum of commerce, is distinguished by the same tests as gold; and it is mainly on account of its malleability that it occurs in flattened grains or scales. *Platiniridium* (4) is another ore somewhat harder. *Iridosmine* (7) resembles platinum; but it scratches glass, and gives the reaction of osmium, besides being rather brittle. *Native Palladium* (5).

SILVER.—The important Silver minerals are: *Native Silver* (2), sectile and malleable like gold, the only one that has a white color; *Argentite* or *Sulphuret of Silver* (40), blackish lead-gray, cutting (unlike the following) nearly like pure lead, cubic in crystallization; *Pyrargyrite* and *Proustite* or Ruby Silver ore (117, 118), ruby red to black, always giving a bright red powder; *Freieslebenite* or Gray Silver ore (114), steel-gray, rather brittle, and powder steel-gray; *Stephanite* or Brittle or Black Silver ore (130), iron-black, and giving an iron-black powder; *Cerargyrite* or *Horn Silver* (140), resembling a dark-colored gray or greenish wax, and cutting like wax; *Embolite* or Chloro-bromid of Silver (141), like the last, but more greenish. These ores yield silver easily, when heated on charcoal. Besides these, *Tetrahedrite* or Gray Copper (125) is often a valuable silver ore; *Galenite* (44), which, although seldom yielding over seventy-five ounces to the ton, affords a considerable part of the silver of commerce. For other rarer silver minerals, see 35, 36, 41, 42, 58–60, 62, 63, 98, 99, 108, 111, 115, 116, 120, 131, 133, 142, 143.

COPPER.—The more valuable species are: *Native Copper* (12); *Chalcopyrite* or *Copper pyrites* (78), of a brass-yellow color, scratched easily with the point of a knife-blade, and giving a greenish-black powder; *Barnhardtite* (79) and *Cubanite* (77), which are similar to the last, but paler; *Bornite* or *Purple Copper* (49), pale yellowish, with a slight coppery tinge, but tarnishing externally to purple, blue, and reddish tints, easily scratched with a knife-blade, and powder grayish; *Chalcocite* or *Vitreous Copper* (61), of a dark lead-gray color, and powder similar, resembling some silver ores, but yielding copper and not silver when heated on charcoal; *Tetrahedrite* or *Gray Copper* (125), of a somewhat paler steel-gray color and powder; *Red Copper* (172); *Black Copper* (178); *Malachite* or *Green Carbonate of Copper* (751), of a bright green color, sometimes earthy in the fracture and sometimes silky; *Azurite* or *Blue Malachite* (752), of a rich deep blue color, either earthy or vitreous in lustre. All the above are acted on by nitric acid, and the solution deposits a red coating of copper on a strip of polished iron; *Chrysocolla* (346), a silicate of copper, resembling the Green Carbonate, but paler green, and usually having a close texture (never fibrous), a smoother surface and somewhat waxy lustre, although occurring usually as an incrustation. *Atacamite* or Chlorid of Copper (153), of deeper green than Malachite; *Sulphate of Copper* (669). For rarer minerals containing copper, see 37, 38, 39, 42, 43, 46, 50, 51, 62, 80, 82, 100–103, 110, 119, 121, 124, 126, 154 (sulphids, arsenids, etc.); 218, 345 (silicates); 533–536, 538–548, 567 583, 615, 622, 623, 636, 639, 644, 665, 670, 700, 705, 706, 708 (phosphates, arsenates, sulphates); 750, 755 (carbonates).

QUICKSILVER.—The only valuable ore is Cinnabar (64) of a bright red to brownish-black color, with a red powder, and affording quicksilver when heated in an open tube. There are also Native Quicksilver (8); Amalgam (9); Selenid (65); Chlorid and Iodid (136, 144). Tetrahedrite (125) sometimes contains this metal.

LEAD.—*Galenite* (44) is the only abundant lead ore; it is a lead-gray, brittle ore, yielding lead when heated with charcoal. The carbonate (cerussite, 729), phosphate (pyromorphite, 493), arsenate (mimetite, 494), and sulphate (anglesite, 633), are rarely worked as ores. For other lead minerals, see 41, 45, 46, 47, 99, 105–107, 111–114, 119, 122–124, 126, 128, 129 (sulphids, antimonids, etc.); 145, 150–152 (chlorids); 177, 197 (oxyds); 502, 539 (arsenates); 505 (antimonate); 656 (phosphate); 616 (tungstate); 617 (molybdate); 619–621, 623 (vanadates); 635, 636, 638, 641, 700 (sulphates); 642–645 (chromates); 712 (selenate); 715, 733 (carbonates).

---

[*] The numbers refer to the number of the species.

ZINC.—The most important ores are: 1, *Smithsonite* or *Carbonate of Zinc* (723), and 2, *Calamine* or *Silicate of Zinc* (361); they are alike in a white, grayish-white, or greenish-white color, commonly a slight waxy lustre and smooth look (often stalactitic or mammillary), yet sometimes earthy; and a hardness such that the surface is scratched with a knife-blade with some little difficulty. They differ in their action with muriatic acid: when the surface is drusy, the silicate shows projections of minute rectangular prisms. *Zincite* or *Red Zinc Ore* (176) is also important; it is bright red and very distinctly foliated. *Blende* or Sulphid of Zinc (56) is a common ore, having a yellow to black color and resinous lustre, and distinctly cleavable; the black varieties are sometimes a little metallic in lustre, but the powder is nearly or quite white. For other Zinc minerals, see 185, 188 (oxyds); 70 (sulphid); 57 (oxysulphid); 238, 241, 266, 270 (silicate); 634, 666 (sulphate); 500 (phosphate); 530, 537 (arsenate); 749, 750 (carbonate).

COBALT, NICKEL.—The ores of cobalt: *Smaltite* (83) and *Cobaltite* (85), both of nearly a tin-white color, with the powder grayish-black, color sometimes verging slightly to gray. The *Black Oxyd of Cobalt* (218), a kind of bog ore and very impure, is sometimes sufficiently abundant to be valuable The useful ores of nickel are *Chloanthite* or the niccoliferous smaltite (83), *Gersdorffite* or *Nickel Glance* (86), *Niccolite* or *Copper Nickel* (71), distinguished by a pale copper-red color, and *Niccoliferous Pyrrhotite* (68), from which the larger portion of the nickel of commerce is extracted. For other ores of *Cobalt*, see 53, 81, 82, 84, 95, 97 (sulphids and arsenids); 618 (molybdate); 667 (sulphate); 526, 529, 530 (arsenate); 748 (carbonate); of *Nickel*, 54, 66 (sulphid); 74, 87, 88 (arsenical or antimonial); 416 (silicate); 668 (sulphate); 527, 529, 530 (arsenate); 747 (carbonate).

MANGANESE.—Common, as *Pyrolusite* (199) and *Psilomelane* (217), both black or grayish-black ores, and having little lustre, and a blackish streak or powder, in which last particular they are distinct from the iron ore called Limonite, with which they are often associated, and also from Hematite or Specular Iron. *Wad* (218) is an earthy bog manganese, sometimes abundant and valuable. *Manganite* (205) is abundant in certain mines, but is of little value in the arts, because of its containing so little oxygen (one-third less than Pyrolusite), to which fact Beudant alludes in his name for the species, *Acerdese;* it differs from pyrolusite in its reddish-brown powder. For other manganese ores, see 52, 76 (sulphid); 73 (arsenid); 195, 196 (oxyds); 241, 262, 263 269, 491 (silicates); 498, 499, 531 (phosphates); 532 (arsenate); 663, 679, 680 (sulphates); 717, 721, 722, 725 (carbonates).

CHROMIUM.—*Chromic Iron* (189), a grayish-black, little lustrous ore, occurring mostly in Serpentine, is the source of chrome in the arts. For different chromates, see p. 614.

IRON.—The important iron ores are: *Hematite* or *Specular Iron* (the αἱματίτης or *bloodstone* of Theophrastus) (180), characterized by its blood-red powder, and occurring either earthy and red, or metallic and dark steel-gray; in the latter condition very hard, a knife-point making no impression; *Magnetite* or *magnetic iron ore* (186), as hard as the preceding, but having a black powder, and being attractable by a magnet; *Franklinite*, an allied species, containing zinc and manganese (188); *Limonite*, called also brown hematite (206), a softer hydrous ore, affording a brownish-yellow powder, earthy or semi-metallic in appearance, and often in mammillary or stalactitic forms; nearly related to limonite are göthite (204), turgite (202), and limnite (213); *Siderite* or *Spathic Iron* (721), a sparry ore, of grayish, grayish-brown, and brown colors, very distinctly cleavable, turning brown to black on exposure. The common clayey iron ores are impure ores, either of Spathic Iron, Limonite, or Hematite; when the last they are red; when brown, reddish-brown, or yellowish-brown to black, they may be either of the two former. One of the most common iron minerals is *Pyrite* or sulphid of iron (75), a pale yellow, brass-like ore, hard enough to strike fire with steel, and thus unlike any copper ore, and all similar ores of other metals. It is frequently mined and utilised for the sulphur it contains. *Marcasite* (90) is similar, but is prismatic and often crested in its forms. *Pyrrhotite* or *Magnetic Pyrites* (68) is less hard and paler, or more grayish in color. *Leucopyrite* and *Mispickel* (91, 93, 94) are white, metallic, arsenical ores, somewhat resembling ores of cobalt. *Menaccanite* or *Titanic Iron* (181) resembles specular iron closely, but has not a red powder; it is abundant in some regions. For other iron minerals, see 260, 284, 334, 369, 435, 436, 467, 469 (silicates); 473–475 (columbates, tantalates); 498, 499, 524, 525, 553, 557, 558, 560, 567–570, 576 (phosphates, arsenates); 605 (borate); 610 (tungstate); 646, 662, 664, 665, 672, 675, 682–687, 692, 696 (sulphates); 717, 719, 720 (carbonates); 758 (oxalate).

TIN.—The only valuable ore is the *Oxyd of Tin* or *Cassiterite* (192), a very hard and heavy mineral of a dark brown to black color, sometimes gray or grayish-brown, without any metallic appearance; the crystals usually have a very brilliant lustre. Tin also occurs as a sulphid (80), and is sparingly found in ores of tantalum and some other mineral species.

TITANIUM.—The only ore of this metal of any value is Rutile (193).

ARSENIC.—*Native Arsenic* (17) is one source of arsenic, but it is too rare to be of much avail also *Orpiment* (27), a sulphur-yellow, foliaceous, and somewhat pearly mineral, and *Realgar* (26) bright red and vitreous. Arsenic is mostly derived for the arts from the arsenical ores of iron cobalt, and nickel.

ANTIMONY.—*Stibnite* or *Gray Antimony* (29) is the source of the antimony of commerce. It is a lead-gray ore, usually fibrous or in prismatic crystals, and distinguished from a similar ore of manganese by its perfect diagonal cleavage and its easy fusibility. Native antimony (18), senarmontite (220), valentinite (221), are sometimes found in sufficient abundance to be mined. Antimony occurs also in numerous ores of lead, silver, and nickel; also as oxysulphid (226).

BISMUTH.—*Native Bismuth* (20), the source of the metal in the arts, is whitish, with a faint reddish tinge, has a perfect cleavage, and is very fusible. For other bismuth ores, see 30–33, 36, 102, 103, 121, 123, 124 (sulphids, tellurids); 222, 223 (oxyds); 336–338 (silicates); 753 (carbonate).

8. Abbreviations.

For explanations of the abbreviations **Var., Comp., Obs., Alt., Artif.**, as headings of sections in the descriptions of species, see p xi; of chemical symbols, pp. xi–xviii; of H., G., B.B., O.F., R.F., p. xx; of other abbreviations, p. xxxiv.

The fractional expression $\frac{2}{2}$, before the statement of an analysis signifies *a mean of two analyses*; $\frac{3}{3}$, a mean of *three*; and so on.

Q in a formula after the new system stands for an accessory ingredient in the compound, and the nature of this ingredient is to be learned from the formula after the old system in the same line.

In the statements of the angles of crystals, abbreviations are used as follows:

pyr., angle over a pyramidal edge.
bas., angle over a basal edge.
mac., angle over a macrodiagonal edge.
brach., angle over a brachydiagonal edge.
top, angle between opposite planes over the summit.
term., angle over terminal edge in a rhombohedron.
adj., angle between adjacent planes.
ov., over; *brachyd.*, brachydiagonal; *macrod.*, macrodiagonal.

DESCRIPTIVE MINERALOGY.

The following are the general subdivisions in the classification of minerals adopted in this treatise:

GENERAL SUBDIVISIONS.

I. NATIVE ELEMENTS.

II. COMPOUNDS: THE MORE NEGATIVE ELEMENT AN ELEMENT OF SERIES II (See next page.)
  1. Binary: SULPHIDS, TELLURIDS, OF METALS OF THE SULPHUR AND ARSENIC GROUPS (p. 26).
  2. Binary: SULPHIDS, TELLURIDS, SELENIDS, ARSENIDS, ANTIMONIDS, BISMUTHIDS, PHOSPHIDS, OF METALS OF THE GOLD, IRON, AND TIN GROUPS (p. 33).
  3. Ternary: SULPHARSENITES, SULPHANTIMONITES, SULPHOBISMUTHITES (p. 84).

III. COMPOUNDS: THE MORE NEGATIVE ELEMENT AN ELEMENT OF SERIES III., GROUP I. (See page 3.)
  1. CHLORIDS, BROMIDS, IODIDS (p. 110).

IV. COMPOUNDS: THE MORE NEGATIVE ELEMENT AN ELEMENT OF SERIES III., GROUP II.
  1. FLUORIDS (p. 123).

V. COMPOUNDS; THE MORE NEGATIVE ELEMENT AN ELEMENT OF SERIES III., GROUP III. Oxygen Compounds.
  1. Binary: OXYDS (p. 131).
  2. Ternary; the basic element an element of Series I.; the acidic of Series II. (as silicon, columbium, phosphorus, etc.); the acidific of Series III. (oxygen): 1, SILICATES (p. 202); 2, COLUMBATES, TANTALATES (p. 512); 3, PHOSPHATES, ARSENATES, ANTIMONATES, NITRATES (p. 526); 4, BORATES (p. 593); 5, TUNGSTATES, MOLYBDATES, VANADATES (p. 601); 6, SULPHATES, CHROMATES, TELLURATES (p. 612); 7, CARBONATES (p. 669); 8, OXALATES (p. 718).

VI. HYDRO-CARBON COMPOUNDS: MINERALS OF ORGANIC ORIGIN (p. 720).

I. NATIVE ELEMENTS.

ARRANGEMENT OF THE SPECIES.

Series I.

1. GOLD GROUP.

1. Gold.
2. Silver.

2. IRON GROUP.

3. Platinum.
4. Platiniridium.
5. Palladium.
6. Allopalladium.
7. Iridosmine.
   (1). Newjarskite.
   (2). Sisserskite.
8. Quicksilver.
9. Amalgam.
10. Arquerite.
11. Gold-Amalgam.
12. Copper.
13. Iron.
14. Zinc.
15. Lead.

3. TIN GROUP.

16. Tin.

Series II.

1. ARSENIC GROUP.

17. Arsenic.
18. Antimony.
19. Allemontite.
20. Bismuth.

2. SULPHUR GROUP.

21. Tellurium.
22. Sulphur.
23. Selensulphur.

3. CARBON-SILICON GROUP.

24. Diamond.
25. Graphite.

Two series of elements are here recognized; the *first* containing the more basic, and the *second*, one division of the more negative. These two series are parallel in their subdivisions, so that the arrangement is a natural one, whether read across, or up and down, the page. The *first* group of each contains elements whose compounds have an *odd* number of atoms of the negative element, as 1, 3, 5, or the *perissads* (p. xviii); the *other two* of each, an *even* number, as 2, 4, 6, or the *artiads*.

(1). To the Gold group of elements belong also *hydrogen*, *potassium*, *sodium*, *lithium*, *rubidium*, *cæsium*, *thallium*; the atomic ratio for the oxyds is 1 : 1, and the general formula of the same RO, or $\mathrm{R^2\Theta}$, in the new system of chemistry.

To the Arsenic group belong the elements *phosphorus*, *nitrogen*, *columbium*, *tantalum*, and probably *boron*. In all but boron, there are oxyds containing 3 and 5 atoms of oxygen; in boron, 3 but not 5.

(2). To the Iron group of elements belong *calcium*, *magnesium*, *aluminum*, *beryllium*, *copper* *cobalt*, *nickel*, *zinc*, *chromium* (in part), *manganese* (in part), *lead* (in part), etc. Among the oxyds the atomic ratio 2 : 2 occurs in the ordinary protoxyds, having the formula RO, as ordinarily written (and so written in this work), but $\mathrm{Ɍ\Theta}$, in the new style of chemistry. The ratio 4 : 6 is represented in the sesquioxyds, $\mathrm{R^2O^3}$ ($\mathrm{Ɍ^2\Theta^3}$ in the new system).

To the Sulphur group of elements belong also *selenium*. *vanadium*, and probably *molybdenum*, in which the more prominent acid has the atomic ratio 2 : 6. Here also may be included that state of the metal *chromium* which exists in chromic acid ($\mathrm{CrO^3}$, or $\mathrm{Ȼr\Theta^3}$), that of *manganese* in manganic acid, and that of *molybdenum* in molybdic acid.

(3). To the Tin group belong also *titanium*, *zirconium*, *thorium*. The prominent oxyd has the atomic ratio 2 : 4 ($\mathrm{RO^2}$, or in the new system $\mathrm{Ɍ\Theta^2}$). This group may contain also that state of *lead* which exists in the oxyd $\mathrm{PbO^2}$ (or $\mathrm{Ᵽb\Theta^2}$): and the same also of *manganese* existing in $\mathrm{MnO^2}$ of platinum and palladium in the deutoxyd state.*

---

* The three states of a basic metal, corresponding to the protoxyd, sesquioxyd, and deutoxyd of the same (in which 1 part of metal balances. in its affinity, 1, 1½, and 2 parts of oxygen), may be

The Carbon-Silicon Group contains *Carbon* and *Silicon*. They are related to one another in the atomic ratio of their prominent acids (SiO^2, CO^2), but they are very widely unlike in many respects, and very strikingly so in the mineral compounds of the two acids.*

Series III.—Besides the above two series of elements, there is a *third*, consisting of the *eminently* negative elements (for the most part exclusively negative). The three groups of this Series III. are:

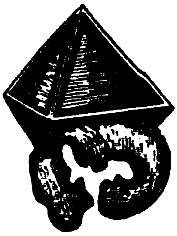
(1). Chlorine, Bromine, Iodine.
(2). Fluorine.
(3). Oxygen.

The first of these groups (like the same in Series I. and II.) includes elements of the *odd* division; the third of the *even*; while fluorine is of either.

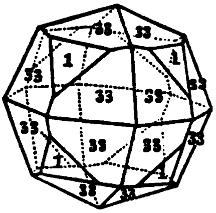
1. GOLD. Sol. *Alchem.* Gediegen Gold *Germ.* Or natif *Fr.*

Isometric. Observed planes *O*, *I*, 1, *i*-2, 3-3, 4-2. Figs. 1 to 8, 15, 17, and the following: the octahedron and dodecahedron (f. 2, 3), most common. Crystals sometimes acicular through elongation of octahedral or other forms; also passing into filiform, reticulated, and arborescent shapes; and occasionally spongiform from an aggregation of filaments; edges of crystals often salient (f. 51). Cleavage none. Twins: composition face octahedral, as in f. 50; and occurring also in trapezohedral and other forms. Also massive and in thin laminæ. Often in flattened grains or scales, and rolled masses in sand or gravel.

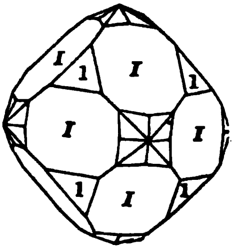
51



52



53



H.=2·5—3. G.=15·6—19·5; 19·30—19·34, when quite pure, G. Rose. Lustre metallic. Color and streak various shades of gold-yellow, sometimes inclining to silver-white. Very ductile and malleable.

Composition, Varieties.—Gold, but containing silver in different proportions, and sometimes also traces of copper, iron, palladium, rhodium.

Var. 1. *Ordinary.* Containing 0·16 to 16 p. c. of silver; or, the atomic ratio of gold to silver varying from 150 : 1 to 3 : 1. Color varying, accordingly, from deep gold-yellow to pale yellow; G.=19—15·5. Ratio for the gold and silver of 3 : 1 corresponds to 15·1 p. c. of silver; 4 : 1, 12 p. c.; 6 : 1, 8 4 p. c.; 10 : 1, 5·3 p. c. (*a*) In distinct crystals or groups of crystals; (*b*) arborescent or reticulated; (*c*) filiform; (*d*) spongy; (*e*) in laminæ; (*f*) rolled masses; (*g*) scales or grains.

2. *Argentiferous*; *Electrum.* (Λευκὸς χουσός *Herod.*; Ἤλεκτρον *Homer*, *Strabo*; Electrum *Plin.* xxxiii. 23.) Color pale yellow to yellowish-white; G.=15·5—12·5. Ratio for the gold and silver

---

designated respectively (using the letters of the Greek alphabet) the *alpha*, *beta*, and *gamma* states. While the iron or Fe in FeO is closely related to magnesium, calcium, etc., that in Fe^2O^3 is as closely related to aluminum; and that in FeS^2, or Pb in PbO^2, or Mn in MnO^2, as closely related to tin and titanium, whose ordinary oxyd is RO^2. This relation is apparent in the crystallographic and chemical characters of the corresponding oxyds. See further on this subject a paper by the author in *Am. Jour. Sci.*, II. xliv., 1867, and Introd., p. xv.

* In strict system, the Silicates should come in classification next before the Carbonates, instead of where they are placed in this work. But as there are no analogies between the species of these two groups, the separation is without serious objection.

of 1 : 1 corresponds to 36 p. c. of silver (anal. 3, 4, 26, 27, 45); 1½ : 1, to 26 p. c. (anal. 15, 41–44), 2 : 1, to 21 p. c. (anal. 54, 55); 2½ : 1, to 18 p. c. (anal. 40). Pliny says that when the proportion of silver in the gold is one-fifth (=20 p. c.) it is called *electrum*. The word in Greek means also *amber*; and its use for this alloy probably arose from the pale yellow color it has as compared with gold.

An argentiferous gold from the Ophir Mine, Nevada, pale yellowish in color, gave Breithaupt (B. H. Ztg., xxv. 169) G.=13·25, 13·68. He observes that it contains more silver than gold, but gives no analysis.

3. *Palladium-Gold*, *Porpezite* Frobel, contains nearly 10 p. c. of palladium, besides some silver; color pale. From Porpez in Brazil. Another variety from Zacotinga and Condonga in Brazil contains 5 to 6 p. c. of palladium.

4. *Rhodium-Gold.* Contains, according to del Rio (Ann. Ch. Phys., xxix. 137), 34–43 p. c. of rhodium; G.=15·5—16·8; brittle. Requires reëxamination.

Analyses by Avdejef (Pogg., liii. 153); Boussingault (Ann. Ch. Phys., xxiv. 408); Forbes (Phil. Mag., IV. xxix. 129, and xxx. 142); T. H. Henry (Phil. Mag., III. xxxiv. 205); Hofmann (Ann. Ch. Pharm., lxx. 255); T. S. Hunt (Rep. G. Can., and Am. J. Sci., II. xx. 448); Kerl (B. H. Ztg., 1853, No. 3); Klaproth (Beitr., iv. 1); A. Levol (Ann. Ch. Phys., II. xxvii. 310); Mallet (J. G. Soc. The average proportion of gold in the native gold of California, as derived from assays of several hundred millions of dollars worth, is 880 thousandths; while the range is mostly between 870 and 890 (Prof. J. C. Booth, of U. S. Mint, in a letter to the author, of May, 1867). The range in the metal of Australia is mostly between 900 and 960, with an average of 925.

The gold of the Chaudière, Canada, contains usually 10 to 15 p. c. of silver; while that of Nova Scotia is very nearly pure.

The Chilian gold afforded Domeyko 84 to 96 per cent. of gold and 15 to 3 per cent. of silver (Ann. d. Mines IV. vi.).

Porpezite afforded Berzelius (Jahresb. 1835) Gold 85·98, palladium 9·85, silver 4·17.

A mass of *electrum*, weighing 25 lbs., from Vöröspatak, consisting of large crystals (¼-½ in.), contained 25 p. c. of silver (Dingl. Polyt. J., clxvi. 396).

Pyrognostic and other Chemical Characters.—B.B. fuses easily. Not acted on by fluxes. Insoluble in any single acid; soluble in nitro-muriatic acid (aqua-regia).

Observations.—Native gold is found, when *in situ*, with comparatively small exceptions, in the quartz veins that intersect metamorphic rocks, and to some extent in the wall rock of these veins. The metamorphic rocks thus intersected are mostly chloritic, talcose, and argillaceous schist of dull green, dark gray, and other colors; also, much less commonly, mica and hornblendic schist, gneiss, diorite, porphyry; and still more rarely, granite. A laminated quartzite, called itacolumite, is common in many gold regions, as those of Brazil and North Carolina, and sometimes specular schists, or slaty rocks containing much foliated specular iron (hematite), or magnetite in grains.

The gold occurs in the quartz in strings, scales, plates, and in masses which are sometimes an agglomeration of crystals; and the scales are often invisible to the naked eye, massive quartz that apparently contains no gold frequently yielding a considerable percentage to the assayer. It is always very irregularly distributed, and never in continuous pure bands of metal, like many metallic ores. It occurs both disseminated through the mass of the quartz, and in its cavities. The larger masses and the finer crystallizations are mainly in the latter; and Prof. Wurtz has suggested that these have been formed by a slow aggregation and crystallization carried on through the solvent power, as regards gold, of persulphate of iron—this salt of iron being derived from the decomposition of the pyrite present in the quartz veins.

The associated minerals are: pyrite, which far exceeds in quantity all others, and is generally *auriferous*; next, chalcopyrite, galena, blende, mispickel, each frequently auriferous; often tetradymite and other tellurium ores, native bismuth, stibnite, magnetite, hematite; sometimes barytes, apatite, fluor, siderite, chrysocolla.

The quartz at the surface, or in the upper part of a vein, is usually cellular and rusted from the more or less complete disappearance of the pyrite and other sulphids by decomposition; but below, it is commonly solid. The enclosing schists are sometimes soft and easily removed in mining. In other cases, they are excessively tough, and the quartz, being a brittle mineral, yields the most easily to the drill.

The gold of the world has been mostly gathered, not directly from the quartz veins, but from the gravel or sands of rivers or valleys in auriferous regions, or the slopes of mountains or hills, whose rocks contain in some part, and generally not far distant, auriferous veins; and such mines are often called *alluvial washings*; in California *placer-diggings*. Pliny speaks of the "bringing of rivers from the mountains, in many instances for a hundred miles, for the purpose of washing the débris," and this method of hydraulic mining is now carried on in California on a stupendous scale. (See Silliman, in Am. J. Sci., II. xl. 10.) The auriferous gravel and earth have been derived from the disintegration or wearing down of auriferous rocks. The auriferous gravel beds in California are of vast extent; those of the Yuba, an affluent of Feather River, varying from 80 to 250 feet in depth, and averaging probably 120 feet. Most of the gold of the Urals, Brazil, Australia, and all other gold regions, has come from such alluvial washings.

The alluvial gold is usually in flattened scales of different degrees of fineness, the size depending partly on the original condition in the quartz veins, and partly on the distance to which it has been transported. Transportation by running water is an assorting process; the coarser particles or largest pieces requiring rapid currents to transport them, and dropping first, and the finer being carried far away—sometimes scores of miles. A cavity in the rocky slopes or bottom of a valley, or a place where the waters may have eddied, generally proves in such a region to be a *pocket* full of gold.

In the auriferous sands, crystals of zircon are very common; also garnet and kyanite in grains; often also monazite, diamonds, topaz, corundum, iridosmine, platinum. The zircons are sometimes mistaken for diamonds.

Gold is widely distributed over the globe, and occurs in rocks of various ages, from the Azoic to the Cretaceous or Tertiary. The schists that contain the auriferous veins were once sedimentary beds of clay, sand, or mud, derived from the wear of preëxisting rocks. Through some process, in which heat was concerned, the latter were metamorphosed into the hard crystalline schists, and at the same time upturned and broken, and often opened between the layers: and then, all the fissures (cutting across the layers) and the openings (made between the layers, and therefore conforming with the lamination) became filled with the quartz veins containing gold. The quartz was brought into the intersecting fissures, and the interlaminated open spaces, from the rocks either side by means of the permeating heated waters (such heated waters, at a temperature much above that of boiling water, having great decomposing and solvent power, and carrying into cavities whatever they can gather up from the rocks). Thus, the gold of the veins was derived from the rocks adjoining the openings, either directly adjoining, or above, or below it; and it must therefore have been widely distributed through these rocks before they were crystallized and the veins were made, although in so infinitesimal a quantity in a cubic foot, that the beds, without the metamorphism and the vein-making, would have been worthless mining ground.

As schists with auriferous quartz veins were made in Azoic time, so were they also in Paleozoic, especially at the great mountain-making epoch which closed the Paleozoic era; also later, in the Jurassic period, as in the Sierra Nevada; and still later in the Cretaceous and Tertiary periods, as in the Coast Mountains of California. But whatever the age of the schists and veins, the original source of all the Paleozoic and later gold deposits must be the azoic or original rocks of the globe, as they are the great source of the material shales and sandstones of all subsequent ages, excepting such as may have been derived from aqueous solution or chemical deposition. Auriferous quartz veins are in no case *igneous* veins—that is, veins filled by injection of melted matter from below.

Gold exists more or less abundantly over all the continents in most of the regions of crystalline rocks, especially those of the semi-crystalline schists; and also in some of the large islands of the world where such rocks exist. In Europe, it is most abundant in Hungary at Konigsberg, Schemnitz, and Felsobanya, and in Transylvania at Kapnik, Vöröspatak, and Offenbanya; it occurs also in the sands of the Rhine, the Reuss, the Aar, the Rhone, and the Danube; on the southern slope of the Pennine Alps from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in many of the streams of Cornwall; near Dolgelly and other parts of North Wales; in Scotland, in considerable amount, near Leadhills, and in Glen Coich and other parts of Perthshire; in the county of Wicklow, Ireland; in Sweden, at Edelfors.

At the Transylvania mines of Vöröspatak, where one piece of 22 ozs. was found, the gold is obtained by mining, and the mines have been worked since the time of the Romans. The Rhine has been most productive between Basle and Manheim; the sands, where richest, contain only about 56 parts of gold in a hundred millions; yet sands containing less than half this proportion are worked. The whole amount of gold in the auriferous sands of the Rhine has been estimated at $30,000,000; but it is mostly covered by soil under cultivation.

In Asia, gold occurs along the eastern flanks of the Urals for 500 miles, and is especially abundant at the Beresov mines near Katharinenburg (lat. 56° 40′ N.); also obtained at Petropavlovski (60° N.); Nischne Tagilsk (59° N.); Miask, near Slatoust and Mt. Ilmen (55° N., where the largest Russian nugget was found), etc. Katharinenburg is the capital of the mining district. The Urals were within the territory of the ancient Scythians; and the vessels of gold reputed, according to Herodotus, to have fallen from the skies, were probably made from Uralian nuggets. But the mines were not opened until 1819; soon after this they became the most productive in the world, and remained so until the discoveries in California. They are principally alluvial washings, and these washings seldom yield less than 65 grains of gold for 4,000 lbs. of soil, and rarely more than 120 grains. At Beresov, there are workings in the parent rock. Siberian mines less extensive occur in the lesser Altai, in the Kolyvan mining region (about 1,500 miles east of Katharinenburg, near long. 100° E., between the Obi and Irtisch, and 1,500 miles west of the other great Siberian mining region, that of Nertschinsk, which is between 135° and 140° E., east of L. Baikal); among the localities are Schlangenberg and Siränovski, noted for affording the electrum (anal. 26, 27). Asiatic mines occur also in the Cailas Mountains, in Little Thibet, Ceylon, and Malacca, China, Corea, Japan, Formosa, Sumatra, Java, Borneo, the Philippines, and other East India Islands.

In Africa, gold occurs at Kordofan, between Darfour and Abyssinia; also, south of the Sahara in Western Africa, from the Senegal to Cape Palmas; in the interior, on the Somat, a day's journey from Cassen; along the coast opposite Madagascar, between 22° and 35° S., supposed by some to have been the *Ophir* of the time of Solomon.

In South America, gold is found in Brazil (where formerly the larger part of the annual produce of the world was obtained) along the chain of mountains lying nearly parallel with the coast, especially near Villa Rica, and in the province of Minas Geraes; in New Granada, at Antioquia, Choco, and Giron; Chili; in Bolivia, especially in the valley of the Rio de Tipuani, east of Sorata; sparingly in Peru. Also in Central America, in Honduras, San Salvador, Guatemala, Costa Rica, and near Panama; most abundant in Honduras, especially along the rivers Guyape and Jálan, in Olancho, while found also in the department of Yoro, and in Southern Honduras.

In North America, there are numberless mines along the mountains of Western America, and others along the eastern range of the Appalachians from Alabama and Georgia to Labrador, besides some indications of gold in portions of the intermediate Azoic region about Lake Superior. They occur at many points along the higher regions of the Rocky Mountains, in Mexico, in New Mexico, near Santa Fé, Cerillos, Avo, etc.; in Arizona, in the San Francisco, Wauba, Yuma, and other districts; in Colorado, abundant, but the gold largely in auriferous pyrites; in Utah and Idaho. Also along ranges between the summit and the Sierra Nevada, in the Humboldt region and elsewhere. Also in the Sierra Nevada, mostly on its western slope (the mines of the eastern being principally silver mines). The auriferous belt may be said to begin in the Californian peninsula. Near the Tejon pass it enters California, and beyond for 180 miles it is sparingly auriferous, the slate rocks being of small breadth; but beyond this, northward, the slates increase in extent, and the mines in number and productiveness, and they continue thus for 200 miles or more. Gold occurs also in the Coast ranges in many localities, but mostly in too small quantities to be profitably worked. The regions to the north in Oregon and Washington Territory, and the British Possessions farther north, are at many points auriferous, and productively so, though to a less extent than California.

The mines of California were first made known in 1849. They were for some years solely alluvial washings, but since 1852 quartz mining has been on the increase. The quartz veins are often of great size. Some in the "Mariposa estate" average 12 feet, and in places expand to 40 feet in breadth. North of Mariposa county, the auriferous gravel, which has everywhere been a principal source of the gold thus far obtained, is very extensive. The thick deposits, often semi-indurated, are now washed down by vast streams of water thrown by the pressure of a column of water of 150 feet, that do the work of running off the earth and gravel, and gathering the gold in an incredibly short time. Much of the auriferous gravel formation is under a covering of volcanic rock, either tufa or lavas, which has to be underworked, in one way or another, to get out the gold, making what is called *table-mountain mining;* the flat tops of hard volcanic material giving a table-like look to the heights. (See J. D. Whitney's Geol. California; review of same in Am. J. Sci., II. xli. 231, 351, and B. Silliman, ib., xl. 1.)

In eastern North America, the mines of the Southern United States produced before the California discoveries about a million of dollars a year. They are mostly confined to the States of Virginia, North and South Carolina, and Georgia, or along a line from the Rappahannock to the Coosa in Alabama. But the region may be said to extend north to Canada; for gold has been found at Albion and Madrid in Maine; Canaan and Lisbon, N. H.; Bridgewater, Vermont; Dedham, Mass. Traces occur also in Franconia township, Montgomery Co., Pennsylvania. In *Virginia*, the principal deposits are in Spotsylvania county, on the Rappahannock, at the United States mines, and at other places to the southwest; in Stafford county, at the Rappahannock gold mines, ten miles from Falmouth, in the Culpepper county, at Culpepper mines, on Rapidan river; in Orange county, at the Orange Grove gold mine, and at the Greenwood gold mines; in Goochland county, at Moss and Busby's mines; in Louisa county, at Walton's gold mine; in Buckingham county, at Eldridge's mine. In *North Carolina*, the gold region is mostly confined to the counties of Montgomery, Cabarrus, Mecklenburg, and Lincoln. The mines of Mecklenburg are principally vein deposits; those of Burke, Lincoln, McDowell, and Rutherford, are mostly in alluvial soil; the Davidson county silver mine has afforded gold. In *Georgia*, the Shelton gold mines in Habersham county have long been famous; and many other places have been opened in Rabun and Hall counties, Lumpkin county, at Dahlonega, etc.; and the Cherokee country. In *South Carolina*, the principal gold regions are the Fairforest in Union district, and the Lynch's creek and Catawba regions, chiefly in Lancaster and Chesterfield districts; also in Pickens county, adjoining Georgia. There is gold also in eastern *Tennessee*.

In Canada, gold occurs to the south of the St. Lawrence, in the soil on the Chaudière (where first found in 1835), and over a considerable region beyond, having been derived probably from the crystalline schists of the Notre Dame range (T. S. Hunt), which is properly a continuation of the mountains of New England and the Appalachians to the southwest. In Nova Scotia, mines are worked near Halifax and elsewhere.

In Australia, which is fully equal to California in productiveness, and much superior in the purity of the metal, the principal gold mines occur along the streams in the mountains of N. S. Wales (S. E. Australia), and along the continuation of the same range in Victoria (S. Australia). It was discovered in N. S. Wales, near Bathurst, in the spring of 1851; and in August of the same year, the far richer deposits of Victoria became known. Some gold has also been obtained in Queensland, N. Australia, in the vicinity of Moreton bay. Prof. Booth states (in a letter to the author) that one lot of Australian gold worth about $4,000, submitted to him in 1853, consisted of grains from the size of a very large pea to small sand, all of which were more or less perfect dodecahedrons. Gold also occurs in Tasmania (Van Diemen's Land). In New Zealand, it has been found at Coromandel harbor, near Auckland, on the Northern island, and on the Middle island near Cook's Straits. Found also in New Caledonia.

Masses of gold of considerable size have been found in North Carolina. The largest was discovered in Cabarrus Co.; it weighed twenty-eight pounds avoirdupois ("steel-yard weight," equals 37 lbs. troy), and was 8 or 9 inches long by 4 or 5 broad, and about an inch thick. The largest mass yet reported from California weighed 20 pounds. A mass consisting of a congeries of crystals, and weighing 201 ozs. (value $4,000) was found in 1865, in California, 7 miles from Georgetown, in El Dorado county. In Paraguay, pieces from 1 to 50 pounds weight were taken from a mass of rock which fell from one of the highest mountains. Several specimens weighing 16 pounds have been found in the Ural, and one of 27 pounds; and near Miask, in the valley of Taschku Targanka, in 1842, a mass was detached weighing 96 pounds troy. This mass is now in the Museum of Mining Engineers at St. Petersburg. A mass found recently in Australia, called the "Blanch Barkley Nugget" had the enormous weight of 146 lbs., and only 6 ozs. of it were gangue; and one still larger, from Ballarat, weighed 184 lbs. 8 ozs., and yielded £8,376 10*s.* 6*d.* sterling of gold.

The yield of gold mines has very much increased in amount since the discovery of the mines of California. The mines of South America and Mexico were estimated by Humboldt, over 30 years since, to yield annually $11,500,000, which much exceeds the present proceeds. Brazil has furnished about 17,500 pounds troy per year. It is estimated that, between 1790 and 1830, Mexico produced $31,250,000 in gold, Chili $13,450,000, and Buenos Ayres $19.500,000, making an average annual yield of $16,050,000. The Russian mines in 1846 produced about $16,500,000; and in 1851, $15,000,000. The yield of California in 1849, the first year after the discovery of the gold, was $5,000,000. It rapidly increased from that year until 1853, when it was nearly $60,000,000. Since then it has diminished, and in 1866 the amount was but $27,000,000. Montana, Colorado, Idaho, and Nevada, raise the total from the United States for the year 1866 to $86,000,000, with $20,000,000 besides of silver. Australia produced $60,000,000 for a number of years; but for 1863, 1864, 1865, the average was not above $30,000,000, one-fourth to one-third of which came from the auriferous quartz.

The gold is obtained from the auriferous quartz by pulverizing, and then treating the finely-powdered quartz with mercury, a method well known to the ancients. This metal dissolves out the gold, producing an amalgam which, by straining and distillation, yields the gold. The auriferous pyrite is first powdered, and then roasted in an oven of peculiar construction until the sulphur is driven off. The residue, according to one process, pronounced the best, is treated with chlorine gas, and the metals thus converted into chlorids, of which the chlorid of gold is soluble. This is removed and then treated with protosulphate of iron, when the gold is deposited. According to another process, the residue is fused with litharge, and the gold is thus combined with lead, and afterward obtained from the lead by cupellation. By a third process, the auriferous pyrite, especially when cupriferous, is concentrated into a copper matt by partial roasting and fusion; the matt is then roasted, and the oxyd of copper taken up by dilute sulphuric acid, leaving the gold and silver in the residue.

2. SILVER. Luna *Alchem.* Gediegen Silber *Germ.* Argent natif *Fr.*

Isometric. Observed planes O, 1, I, i-2, i-4, 3-3. Figs. 1, 2, 6, 7, 15, 17. Cleavage none. Twins: composition face octahedral, like f. 50; but occurring also in the trapezohedron 3-3, and other forms. Commonly coarse or fine filiform, reticulated, arborescent; in the latter, the branches pass off either (1) at right angles, and are crystals (usually octahedrons) elongated in the direction of a cubic axis, or else a succession of partly overlapping crystals; or (2) at angles of 60°, they being elongated in the direction of a dodecahedral axis. Crystals generally obliquely prolonged or shortened, and thus greatly distorted. Also massive, and in plates or superficial coatings.

H.=2·5—3. G.=10·1—11·1, when pure 10·5. Lustre metallic. Color and streak silver-white; subject to tarnish, by which the color becomes grayish-black. Ductile.

Comp., Var.—Silver, with some copper, gold, and sometimes platinum, antimony, bismuth, mercury.

Var. 1. *Ordinary.* (*a*) crystallized; (*b*) filiform, arborescent; (*c*) massive.

2. *Auriferous; Küstelite.* (Güldisch-Silber *Hausm.*, Handb. 104, 1813. Küstelit *Breith.*, B. H. Ztg., xxv. 169, 1866.) Contains 10 to 30 p. c. of silver; color white to pale brass-yellow. There is a gradual passage to argentiferous gold (see GOLD).

The name *Küstelite* was given to an ore from Nevada, having the following characters: H.=2—2½; G.=11·32—13·10; color silver-white, somewhat darker than native silver on a fresh surface; Richter found in it silver, lead, and gold, the first much predominating. From the lode of the Ophir mine, Nevada, in bean-shaped grains.

3. *Cupriferous.* Contains sometimes 10 p. c of copper.

4. *Antimonial.* John found in silver from Johanngeorgenstadt (Chem. Unt., i. 285) 1 p. c. antimony, and traces of copper and arsenic. (See further under Discrasite.)

The Kongsberg native silver contains 0·40 p. c. of *mercury* (D. Forbes), and the presence of this metal, Seemann suggests, may account for its fine crystallization.

Fordyce (Phil. Trans., 1776, 523) found in silver from Kongsberg, Norway, silver 72, gold 28. Berthier (Ann. d. M., xi. 72) obtained 10 p. c. of copper from silver from Curcy, France.

Pyr., etc.—B.B. on charcoal fuses easily to a silver-white globule, which in O.F. gives a faint dark red coating of oxyd; crystallizes on cooling. Soluble in nitric acid, and deposited again by a plate of copper.

Obs.—Native silver occurs in masses, or in arborescences and filiform shapes, in veins traversing gneiss, schist, porphyry, and other rocks. Also occurs disseminated, but usually invisibly, in native copper, galena, chalcocite, etc.

The mines of Kongsberg in Norway, have afforded magnificent specimens of native silver. One among the splendid suite from this locality in the Royal collection at Copenhagen, weighs upwards of 5 cwt., and recently two masses have been obtained weighing severally 238 and 436 pounds. The principal Saxon localities are at Freiberg, Schneeberg, and Johanngeorgenstadt; the Bohemian, at Przibram, and Joachimsthal. A mass weighing 60 lbs. from the Himmelsfurst mine near Freiburg had G.=10·840. It also occurs in small quantities with other ores, at Andreasberg, in the Hartz; in Suabia; Hungary; at Allemont in Dauphiny; in the Ural near Beresof; in the Altai, at Zmeoff; and in some of the Cornish mines.

Mexico and Peru have been the most productive countries in silver. In Mexico, it has been obtained mostly from its ores, while in Peru it occurs principally native. A Mexican specimen from Batopilas weighed when obtained 400 pounds; and one from Southern Peru (mines of Huantaya) weighed over 8 cwt. During the first eighteen years of the present century, more than 8,180,000 marks of silver were afforded by the mines of Guanaxuato alone. In Durango, Sinaloa, and Sonora, in Northern Mexico, are noted mines affording native silver.

In the United States it is disseminated through much of the copper of Michigan, occasionally in spots of some size, and sometimes in cubes, skeleton octahedrons, etc., at various mines. It has been observed at a mine a mile south of Sing Sing prison, which was formerly worked for silver; at the Bridgewater copper mines, New Jersey; in interesting specimens at King's mine, Davidson Co., N. C.; at Prince's location, Lake Superior, Canada; rarely in filaments with barytes at Cheshire, Ct. In Idaho, at the "Poor Man's lode," large masses of native silver have been obtained. In Nevada, in the Comstock lode, it is rare, and mostly in filaments; at the Ophir mine rare, and disseminated or filamentous; in California, sparingly, in Silver Mountain district, Alpine Co.; in the Maris vein, in Los Angeles Co.; in the township of Ascot, Canada. The yield of the United States at the present time in silver is about $20,000,000.

Alt.—Pseudomorphs, consisting of horn silver, red silver ore, and argentite.

---

3. PLATINUM. Platina (fr. Choco) *Ulloa*, Relac. Hist. Viage Amer. Merid., lib. 6, c. 10 Madrid 1748. Platina (fr. Carthagena) *W. Brownrigg* (who received it in 1741 from C. Wood), Phil Trans. 1750, 584. Platina del Pinto *Scheffer*, Ac. H. Stockh. 1752, 269. Polyxen *Hausm.*, Handb., 97, 1813, 20, 1847.

Isometric. Rarely in cubes or octahedrons (f. 1, 2). Usually in grains; occasionally in irregular lumps. Cleavage none.

H.=4—4·5. G.=16—19, 17·862, 17·759, two masses, G. Rose, 17·200, a smaller; 17·108, small grains, Breith.; 17·608, a mass, Breith.; 17·60, large mass from Nischne Tagilsk, Sokoloff. Lustre metallic. Color and streak whitish steel-gray; shining. Opaque. Ductile. Fracture hackly. Occasionally magneti-polar.

Comp.—Platinum combined with iron, iridium, osmium, and other metals. Analyses; 1—3, Berzelius (Ac. H. Stockholm 1828, 113); 4, 5, Osann (Pogg., viii. 505, xi. 411, xiii. 283, xiv. 329, xv. 158); 6, 7, Svanberg (Institut, ii. 294); 8 M. Böcking (Ann. Ch. Pharm., xcvi. 243); 9—20, H. St. C. Deville & Debray (Ann. Ch. Phys. III., lvi. 449); 21, Kromayer (Arch. Pharm. II., cx. 14, Jahresb., 1862, 707):

* the loss, with some osmium.

Var.—(1) Svanberg makes the Platinum of Nos. 2, 7, 8=Fe Pt^3; Fe Pt^4; (2) that of 3, 4, 5= Fe Pt^2. The last is called *Iron-Platinum* (*Eisenplatin, Breith.*); G.=14·6—15·8, H.=6.

Pyr., etc.—Infusible. Not affected by borax or salt of phosphorus, except in the state of fine dust, when reactions for iron and copper may be obtained. Soluble only in heated nitro-muriatic acid. Acts slightly on the magnet; this property has been supposed to depend on the amount of iron it contains; but Kokscharof states that platinum masses from Nischne Tagilsk are magneti-polar, and attract iron filings far more strongly than the ordinary magnet.

Obs.—Platinum was first found in pebbles and small grains, associated with iridium, osmium, palladium, gold, copper, and chromite, in the alluvial deposits of the river Pinto, in the district of Choco, near Popayan, in South America, where it received its name *platina*, from *plata*, *silver*. In the province of Antioquia, in Brazil, it has been found in auriferous regions in syenite (Boussingault).

In Russia, where it was first discovered in 1822, it occurs at Nischne Tagilsk, and Goroblagodat, in the Ural, in alluvial material; the gravel has been traced to a great extent up Mount La Martiane, which consists of crystalline rocks; in Nischne Tagilsk, it has been found with chromite in serpentine. Formerly used as coins by the Russians. Russia affords annually about 800 cwt. of platinum, which is nearly ten times the amount from Brazil, Columbia, St. Domingo, and Borneo. The amount coined from 1826 to 1844, equalled two and a half millions of dollars.

Platinum is also found on Borneo, which furnishes 600 to 800 lbs. annually; in the sands of the Rhine; at St. Aray, val du Drac; county of Wicklow, Ireland; on the river Jocky. St. Domingo; according to report, in Cholotcca and Gracias, in Honduras; in California, in the Klamath region, at Cape Blanco, etc., but not abundant; in traces with gold in Rutherford Co., North Carolina; at St. François Beauce, etc., Canada East.

Although platinum generally occurs in quite small grains, masses are sometimes found of considerable magnitude. A mass weighing 1,088 grains was brought by Humboldt from South America, and deposited in the Berlin museum; specific gravity 18·94. In 1822, a mass from Condoto was deposited in the Madrid museum, measuring two inches and four lines in diameter, and weighing 11,641 grains. A specimen was found in the year 1827, in the Ural, not far from the Demidoff mines, which weighed $10\frac{2}{16}$ Russian pounds, or 11·57 pounds troy, and similar masses are not uncommon; the largest yet seen weighed 21 pounds troy, and is in the Demidoff cabinet.

The metal platinum was brought from Choco, S. A., by Ulloa, a Spanish traveller in America, in the year 1735, and from Carthagena, by Charles Wood, who procured it in Jamaica. Ulloa speaks of specula made by the people of the country, of a peculiar metal, which Brownrigg says was "platina," and the latter mentions a "pummel of a sword," and other articles of platinum, received by him from Carthagena.

4. PLATINIRIDIUM. *Svanberg*, Jahresb., xv. 205, 1834.

Isometric. In small grains with Platinum; sometimes in cubes with truncated angles, (f. 6). H.=6—7; G.=22·6—23. Color white.

Comp.—Platinum and iridium in different proportions. Analyses by Svanberg:

	Plat.	Irid.	Pallad.	Rhod.	Fe	Cu	Os	
1. N. Tagilsk	19·64	76·80	0·89	——	——	1·78	——	=99·11
2. Brazil	55·44	27·79	0·49	6·86	4·14	3·30	*trace*	=98·02

Prinsep, in a specimen from Ava in India, found 60 of iridium and 20 of platinum. If platinum and iridium are isomorphous, it is probable that the proportions of these metals are indefinite.

Dr. Genth, after some trials, considers some grains occurring with the California gold to be Platiniridium. Am. J. Sci. II., xv. 246.

5. PALLADIUM. *Wollaston*, Phil. Trans. 1808.

Isometric. In minute octahedrons, Haid. Mostly in grains, sometimes composed of diverging fibres.

H.=4·5—5. G.=11·3—11·8, Wollaston; of hammered, 12·148, Lowry. Lustre metallic. Color whitish steel-gray. Opaque. Ductile and malleable.

Comp.—Palladium, alloyed with a little platinum and iridium, but not yet analyzed.

Pyr., etc.—The blowpipe reactions of *native* palladium are undescribed. As prepared by Deville, it is the most fusible of the platinum metals. Oxydizes at a lower temperature than silver, but is not blackened by sulphurous gases.

Obs.—Palladium occurs with platinum, in Brazil, where quite large masses of the metal are sometimes met with; also reported from St. Domingo, and the Ural.

Palladium has been employed for balances; also for the divided scales of delicate apparatus, for which it is adapted, because of its not blackening from sulphur gases, while at the same time it is nearly as white as silver.

6. ALLOPALLADIUM. Selenpalladium *Zinken*, Pogg., xvi. 496, 1829. Palladium pt.

Hexagonal, Zinken. In small six-sided tables. Cleavage: basal perfect. Lustre bright. Color nearly silver-white to pale steel-gray.

Comp.—Palladium, under the hexagonal system, the metal being dimorphous; the formula probably Pd^2, instead of Pd.

Obs.—From Tilkerode, in the Harz, in small hexagonal tables with gold.

7. IRIDOSMINE. Ore of Iridium, consisting of Iridium and Osmium, *Wollaston*, Phil. Trans., 1805, 316 (Metals Iridium and Osmium, first announced by *Tennant*, Phil. Trans., 1804, 411). Native Iridium *Jameson*. Osmiure d' Iridium *Berz.*, Nouv. Syst. Min., 195, 1819. Osmium-Iridium *Leonh.*, Handb., 1821. Iridosmium; Osmiridium. Newjanskit, Sisserskit, *Haid.* Handb., 558, 1845.

Hexagonal. Rarely in hexagonal prisms with replaced basal edges; pyramidal angle, 127° 36′, basal, 124°. Commonly in irregular flattened grains.

H.=6—7. G.=19·3—21·12. Lustre metallic. Color tin-white, and light steel-gray. Opaque. Malleable with difficulty.

Comp. Var.—Iridium and osmium in different proportions. Two varieties depending on these proportions have been named as species, but they are isomorphous, as are those of the metals (G Rose). Some rhodium, platinum, ruthenium, and other metals are usually present.

Var. 1. *Newjanskite*, Haid.; H.=7; G.=18·8—19·5. In flat scales; color tin-white. Over 40 p. c. of Iridium. Named from a Siberian locality.

Analysis by Berzelius (Pogg., xxxii. 232, 1833):

Ir 46·77, Os 49·34, Rd 3·15, Fe 0·74, giving the formula Ir Os=Iridium 49·78, Osmium 50·22 G.=19·386—19·471.

Claus obtained (Beitr. Platinum, Dörpat, 1854) from six-sided tables from Nischne-Tagilsk:

Ir 55·24 Os 27·32 Pl 10·08 Rd 1·50 Pd Fe Cu *tr*,=100.

Deville and Debray (Ann. Ch. Phys., III. lvi. 481) found:

			Ir	Rd	Pt	Ru	Os	Cu	Fe
1.	N. Grenada		70·40	12·30	0·10	——	[17·20]	——	——=100
2.	"		57·80	0·63	——	6·37	35·10	0·06	0·10=100·06
3.	California		53·50	2·60	——	0·50	[43·40]	——	——=100
4.	Australia		58·13	3·04	——	5·22	[33·46]	0·15	——=100

			Ir	Rd	Pt	Ru	Os	Cu	Fe
8.	Russia	G.=18·8	64·50	7·50	2·80	——	[22·90]	0·90	1·40=100
9.	"	G.=20·4	43·94	1·65	0·14	4·68	[48·85]	0·11	0·63=100
10.	"	G.=20·5	70·36	4·72	0·41		[23·01]	0·21	1·29=100

Thomson found in a steel-gray variety from Brazil 72·9 p. c. of iridium, with 24·1 osmium and 2·6 iron=100.

2. *Sisserskite* Haid. In flat scales, often six-sided, color grayish-white, steel-gray. G=20—21·2. Not over 30 p. c. of iridium. One kind from Nischne Tagilsk afforded Berzelius (l. c.) Ir Os^4=Iridium 19·9, osmium 80·1=100; G.=21·118. Another corresponded to the formula Ir Os^3=Iridium 24·8, osmium 75·2=100, it affording Ir 25, Os 75. Named from a Siberian locality.

Pyr., etc.—At a high temperature the Sisserskite gives out osmium, but undergoes no further change. The Newjanskite is not decomposed and does not give an osmium odor. With nitre, the characteristic odor of osmium is soon perceived, and a mass obtained soluble in water, from which a green precipitate is thrown down by nitric acid.

Obs.—It occurs with platinum in the province of Choco in South America; near Katharinenburg, Slatoust, and Kyschtimsk, in the Ural mountains; in Australia. It is rather abundant in the auriferous beach-sands of northern California, occurring in small bright lead-colored scales, sometimes six-sided. Also traces in the gold-washings on the rivers du Loup and des Plantes, Canada.

8. **MERCURY.** Χυτὸς ἄργυρος *Theophr.* Ὑδράργυρος καθ' ἑαυτὴν [native] *Dioscor.*, E, cx. Argentum vivum, Hydrargyros, *Plin.* xxxiii. 32, 20, 41. Quicksilver. Mercurius *Alchem.* Gediegen Quecksilber *Germ.* Mercure natif *Fr.*

Isometric. Occurs in small fluid globules scattered through its gangue. G.=13·568. Lustre metallic. Color tin-white. Opaque.

Comp.—Pure mercury (Hg); with sometimes a little silver.

Pyr., etc.—B.B., entirely volatile, vaporizing at 662° F. Becomes solid at —39° F, and may be crystallized in octahedrons. Dissolves readily in nitric acid.

Obs.—Mercury in the metallic state is a rare mineral; the quicksilver of commerce is obtained mostly from cinnabar, one of its ores. The rocks affording the metal and its ores are mostly clay shales or schists of different geological ages.

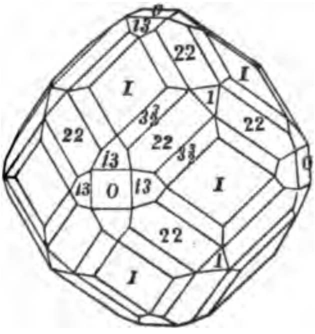
At Cividale, in Venetian Lombardy, it is found in a marl regarded as a part of the Eocene nummulitic beds. Mercury has been observed occasionally in *drift;* and near Eszbetek, in Transylvania, and also Newmarkt, in Galicia, springs, issuing from the Carpathian sandstone, sometimes bear along globules of mercury. Its most important mines are those of Idria, in Carniola, and Almaden in Spain. At Idria it occurs interspersed through a clay slate, from which it is obtained by washing. It is found in small quantities at Wölfstein and Mörsfeld, in the Palatinate, in Carinthia, Hungary, Peru, and other countries; also at Peyrat le Chateau, in the department of the Haute Vienne, in a disintegrated granite, unaccompanied by cinnabar; in California, especially at the Pioneer mine, in the Napa Valley, where some of the quartz geodes contain several pounds of mercury.

9. **AMALGAM.** Quicksilfwer amalgameradt med gediget Silfwer (fr. Sala) *Cronst.*, 189, 1758. Naturlich Amalgam, Silberamalgam, *Germ.* Amalgam natif *de Lisle*, i. 420, 1783. Mercure argental *H.* Pella natural *Del Rio.*

Isometric. Observed planes, as in f. 54, with also plane 2. Figure 3 common; also 4, 5, 8, 9, 13, 14. Cleavage: dodecahedral in traces. Also massive.

H.=3—3·5. G.=13·75—14; 13·755, Haid. Color and streak silver-white. Opaque. Fracture conchoidal, uneven. Brittle, and giving a grating noise when cut with a knife.

54



Comp.—Both Ag Hg^2 (=Silver 34·8, mercury, 65·2), and Ag Hg^3 (=Silver 26·25, and mercary, 73·75), are here included as afforded by the following analyses: 1, Klaproth (Beitr., i. 182); 2, Cordier (J. d. M., xii. 1, Phil. Mag., xix. 41); 3, Heyer (Crell's Ann., ii. 90):

	Silver.	Mercury.
1. $Ag\,Hg^2$, Moschellandsberg	36	64 =100 Klaproth.
2. $Ag\,Hg^3$, Allemont?	27·5	72·5=100 Cordier.
3. " Moschellandsberg	25·0	73·3= 98·3 Heyer.

Pyr., etc.—B.B., on charcoal the mercury volatilizes and a globule of silver is left. In the closed tube the mercury sublimes and condenses on the cold part of the tube in minute globules Dissolves in nitric acid. Rubbed on copper it gives a silvery lustre.

Obs.—From the Palatinate at Moschellandsberg, in fine crystals, and said to occur where the veins of mercury and silver intersect one another. Also reported from Roseuau in Hungary, Sala in Sweden, Allemont in Dauphiné, Almaden in Spain.

Domeyko reports (Min., 187, Ann. d. M., VI. ii. 123, v. 453) other compounds from the mines of La Rosilla, province of Atacama; one of white color, with Hg 56·4, Ag 43·6; 2, white with (mean of 3 anal.) Hg 53·2, Ag 46·8=$Ag^3\,Hg^4$; 3, granular and dull, (mean of 3 anal.) Hg 44·9, Ag 55·1=Ag Hg, 4, blackish and dull, (mean of 3 anal.) Hg 46·6, Ag 53·4; 5, blackish and dull metallic, sometimes in crystals, Hg 35·8, Ag 64·2=Ag^4H^3.

Of the last there is a mass in the museum at Santiago, Chili, weighing 21¾ lbs. These may be only mixtures of a true chemical amalgam with silver.

10. ARQUERITE. Arquerite *Berth., de B., & Duf.*, C. R., xiv. 567, 1842, in Rep. on Art. by *Domeyko*, pub. in Ann. d. M., III. xx. 268, 1841.

Isometric. In regular octahedrons; also in grains, small masses, and dendrites. G.=10·8. In color, lustre, ductility like native silver, but softer.

Comp.—According to Domeyko (l. c.) the crystallized contains $Ag^6\,Hg$=Silver 86·5, mercury 13·5=100.

Obs.—From the mines of Arqueros, in Coquimbo, Chili, where it is the principal ore In the first fifteen years of exploration these mines afforded 200,000 marcs of silver. Occurs with barite, cobalt bloom, and little sulphuret and chlorid of silver.

11. GOLD AMALGAM. *H. Schneider*, J. pr. Ch., xliii. 317, 1848.

In small white grains as large as a pea, easily crumbling (Columbia variety); also in yellowish-white, four-sided prisms (California variety).

Comp.—$(Au, Ag)^2\,Hg^5$, an analysis by Schneider of a specimen from Columbia (l. c.), affording, mercury 57·40, gold 38·39, silver 5·0.

The California amalgam gave Sonnenschein (ZS. G., vi. 243), gold 39·02, mercury 60·98; also another, gold 41·63, mercury 58·37, in which Au: Hg=2: 3.

Obs.—From the platinum region of Columbia, along with platinum; California, especially near Mariposa.

12. COPPER. Aes Cyprium *Plin.* Venus *Alchem.* Gediegen Kupfer *Germ.* Cuivre natif *Fr.*

Isometric. Observed forms *O*, 1, *I*, *i*-2, *i*-$\frac{3}{2}$, 3-3. Figs. 1, 2, 3, 4, 5, 6, 7, 8, 16, 17, and others. Cleavage none. Twins; composition-face octahedral, very common, and producing, in connection with distortion, complex forms; one a double six-sided pyramid, made of the six planes *i*-2 about one cubic angle of f. 17, and the six about the diagonally opposite, the rest wanting. Often filiform and arborescent; the latter with the branches passing off usually at 60°, the supplement of the dodecahedral angle; the branches sometimes twin-dodecahedrons modified by planes *O*, 1, and the composition-face longitudinal, but contained under only one dodecahedral plane along the upper side of the branch, and either side of this one octahedral and one cubic, with an oblique extremity made up of two cubic planes (Rose). Also massive.

H.=2·5—3. G.=8·838, native, Whitney; 8·948—8·958, electrotype copper, Dick. Lustre metallic. Color copper-red. Streak metallic shining. Ductile and malleable. Fracture hackly.

Comp.—Pure copper, but often containing some silver, bismuth, etc.

P. Collier obtained 0·015 p. c. silver in native copper from the Minnesota mine. (Private communication.)

Hautefeuille states that a Lake Superior specimen afforded him, Copper 69·280, silver 5·548, mercury 0·0119, gangue 25·248 (C. R., xliii. 166); while F. A. Abel found in a specimen of same, which had a thick vein of native silver running through it (J. Ch. Soc., II. i. 89), 0·002 p. c. of silver, with a trace of lead, and in another 0·56 of silver. Abel obtained for a Uralian, from the Kirghiz District, 0·034 silver, 0·11 bismuth, a trace of lead, and 1·28 of arsenic.

Pyr., etc.—B.B. fuses readily; on cooling, becomes covered with a coating of black oxyd. Dissolves readily in nitric acid, giving off red nitrous fumes, and produces a deep azure-blue solution with ammonia.

Obs.—Copper occurs in beds and veins accompanying its various ores, and is most abundant in the vicinity of dikes of igneous rocks. It is sometimes found in loose masses imbedded in the soil.

In Siberia, and the island of Nalsoe, in Faroe, it is associated with mesotype, in amygdaloid, and though mostly disseminated in minute particles, sometimes branches through the rock with extreme beauty. At Turinsk, in the Urals, in fine crystals. Common in Cornwall, at many of the mines near Redruth; and also in considerable quantities at the Consolidated mines, Wheal Buller, and others. Brazil, Chili, Bolivia, and Peru afford native copper; a mass now in the museum at Lisbon, supposed to be from a valley near Bahia, weighs 2,616 pounds; north of Tres Puntos, desert of Atacama, a large vein was discovered in 1859. In Bolivia, at Corocoro, in sandstone, and called in commerce "*Barilla de Cobre*" (copper barilla). Also found at some localities in China and Japan.

This metal has been found native throughout the red sandstone (Triassico-Jurassic) region of the eastern United States, in Massachusetts, Connecticut, and more abundantly in New Jersey, where it has been met with sometimes in fine crystalline masses, especially at New Brunswick, Somerville, Schuyler's mines, and Flemington. One mass from near Somerville, on the premises of J. C. Van Dyke, Esq., of N. Brunswick, weighed 78 pounds, and is said originally to have weighed 128. Near N. Brunswick a vein or sheet of copper, a line or so thick, has been traced for several rods. Near New Haven, Conn., a mass was formerly found weighing 90 pounds.

No known locality exceeds in the abundance of native copper the Lake Superior copper region, near Kewenaw Point, where it exists in veins that intersect the trap and sandstone. The annual yield of native copper at the present time is about 8,000 tons. Masses of great size were observed in this district near the Ontanagon river, by Mr. Schoolcraft, in 1821. The largest single mass yet found was discovered in February, 1857, in the Minnesota mine, in the belt of conglomerate, which forms the foot-wall of the vein. It was 45 feet in length, 22 feet at the greatest width, and the thickest part was more than 8 feet. It contained over 90 p. c. copper, and weighed about 420 tons. This copper contains silver, sometimes in visible grains, lumps, or strings, and occasionally a mass of copper, when polished, appears sprinkled with large silver spots, resembling, as Dr. Jackson observes, a porphyry with its feldspar crystals. The copper occurs in trap or sandstone, near the junction of these two rocks, and has probably been produced through the reduction of copper ores. It is associated with prehnite, datolite, analcite, laumontite, pectolite, epidote, chlorite, wollastonite, and sometimes coats amygdules of calcite, etc., in amygdaloid. Strings of copper often reticulate through crystals of analcite and prehnite. Pseudomorphs after scalenohedrons of calcite are sometimes met with. Besides this occurrence in the vicinity of trap, it is also in some parts of the Kewenaw region distributed widely in grains through the sandstone.

Native copper occurs sparingly in California; at the Union and Keystone, Napoleon and Lancha Plana mines in Calaveras Co.; in the Cosumnes mine, Amador Co.; in serpentine, in Sta. Barbara Co. Also on the Gila river in Arizona; in large drift masses in Russian America.

13. IRON. Mars *Alchem.* Gediegen Eisen *Germ.* Fer natif *Fr.*

Isometric. Cleavage octahedral.

H.=4·5. G.=7·3—7·8; 7·318 a partially oxydized fragment of a crystal of meteoric iron from Guilford Co., N. C. Lustre metallic. Color iron-gray. Streak shining. Fracture hackly. Ductile. Acts strongly on the magnet.

Obs.—The occurrence of masses of native iron apart from that of meteoric origin is not placed beyond doubt. An iron so regarded, with some reason, occurs in the hill country above Bexley in Bassa Co., Liberia, Africa. An analysis afforded A. A. Hayes (Am. J. Sci., II. xxi. 153) iron 98·40, quartz grains, magnetite and a zeolite 1·60=100. The mass of iron, from Canaan, Ct., published as native, was artificial. A fragment of iron found near Knoxville, Tenn., but of uncertain exact locality and possibly meteoric, afforded Genth (ib., xxviii. 246) Iron 99·79, nickel 0·14, magnesium 0·022, calcium 0·121, silicium 0·075, cobalt *trace*=100·148. Cramer describes a mass weighing four pounds, obtained in the mine of Hackenburg. It is said to have been observed in thin laminæ in an ironstone conglomerate in Brazil, and in lava in Auvergne; also in the keuper in Thuringia, in an argillaceous sandstone, containing fossils; it afforded but a trace of nickel: G.=5·24, (Pogg., lxxxviii. 1853, 145, where other localities are mentioned); also at Chotzen in Bohemia, in a limestone (the *Planerkalk*), affording on analysis Fe 98·83, graphite 0·74, As 0·32, Ni 0·61, and thought to be possibly an ancient meteorite (Jahrb. G. Reichs., viii. 354).

The presence of metallic iron in grains in basaltic rocks (from Giant's Causeway, etc.) has been announced by Dr. Andrews. After pulverizing the rock and separating by means of a magnet the grains that were attracted by it, he subjected the grains to the action of an acid solution of sulphate of copper in the field of a microscope, which salt, when there is a trace of *pure* iron present, gives a deposit of copper; and in his trials there were occasional deposits of copper in crystalline bunches. It has been noticed in other related rocks.

Meteoric iron usually contains 1 to 20 per cent. of nickel, besides a small percentage of other metals, as cobalt, manganese, tin, copper, chromium; also phosphorus common as a phosphuret, sulphur in sulphurets, carbon in some instances, chlorine.

For a review of papers on meteoric iron, see Rammelsberg's Handbuch der Mineralchemie (Liepzig, 1860). The following are a few analyses: 1, Berzelius (Ac. H. Stockh., 1834, Pogg., xxxiii. 123); 2, Bergemann (Pogg., lxxviii. 406); 3, W. S. Clarke (Ann. Ch. Pharm., lxxxii. 367); 4, Berzelius (Ac. H. Stockh., 1832, Pogg., xxvii. 118); 5, J. L. Smith (Am J. Sci., II. xix. 153):

	1	2	3	4	5
	Siberia.	Zatatecas, Mexico.	Lenarto.	Bohumilitz.	Knoxville, Tenn

	100·000	100·33	99·223	100·00	99·57

Reichenbach has named the alloy of iron and nickel, containing up to 23 p. c. of the latter, *Chamasite*; that approaching probably the formula $Fe^4 Ni^2$, *Tænite*; and to that having the formula Fe Ni, Shepard has applied the name *Oktibbehite*. The phosphorus in the analyses is combined with iron as *Schreibersite*; the sulphur as *Troilite*; the magnesia, in anal. 5, with the silica probably as *Enstatite*.

Among large iron meteorites, the Gibbs meteorite, in the Yale College cabinet, weighs 1,635 lbs.; length three feet four inches; breadth two feet four inches; height one foot four inches. It was brought from Red River. The Tucson meteorite, now in the Smithsonian Institution, weighs 1,400 lbs.; it was originally from Sonora. It is ring-shaped, and is 49 inches in its greatest diameter. Still more remarkable masses exist in South America; one was discovered by Don Rubin de Celis in the district of Chaco-Gualamba, whose weight was estimated at 32,000 lbs.; and another was found at Bahia in Brazil, whose solid contents are at least twenty-eight cubic feet, and weight 14,000 lbs. The Siberian meteorite, discovered by Pallas, weighed originally 1,600 lbs. and contained imbedded crystals of chrysolite. Smaller masses are quite common. Meteoric iron is perfectly malleable, and may be readily worked in a forge, and put to the same uses as manufactured iron.

Bahr has observed grains of native iron in a fragment of petrified wood. The iron was mixed with limonite and organic matter, and is supposed to have been produced by the deoxydation of a salt of iron by the organic matter of the wood. He calls the iron *Siderofferrite*.

Von Dechen reports that an artificial iron has been observed by him, which has *cubic* cleavage (Verh. nat. Ver. Bonn, 1861.)

14. ZINC.

Hexagonal, Rose. Cleavage: basal perfect.

H.=2. G.=7. Lustre metallic. Color and streak white, slightly grayish.

Comp.—Zinc, with sometimes a trace of cadmium and other metals.

Obs.—Reported by G. Ulrich as having been found in a geode in basalt, near Melbourne, Victoria Land, Australia; the piece weighed 4½ ozs., and was incrusted with smithsonite and aragonite, and some cobalt bloom. Also said to occur in the gold sands of the Mittamitta river, north of Melbourne, along with topaz, corundum, etc.; a single piece, according to L. Becker, having been found which contained traces of cadmium and other metals. (L. Becker, in Trans. Phil Inst., Victoria, 1856, and Jahrb. Min., 1857, 312, 698; G. Ulrich, in B. H. Ztg., xviii. 63.) It should be stated that the zinc said to come from the Melbourne basalt was found by a quarryman and not by a scientific observer, and that therefore there may be an error with regard to its actually having been taken from the basalt. The existence of native zinc seems still to need confirmation.

Stolba has recently obtained artificially hexagonal crystals of zinc, six-sided prisms with low pyramidal terminations (J. pr. Ch., xcvi. 182). Zinc is supposed to occur also in isometric forms (Am. J. Sci., II. xxxi. 191).

15. LEAD. Plumbum nigrum *Plin.*, xxxiv. 47. Saturnus *Alchem.* Gediegen Blei *Germ.* Plomb natif *Fr.*

Isometric. Found in thin plates and small globules.

H.=1·5. G.=11·445, when pure. Lustre metallic. Color lead-gray. Malleable and ductile.

Comp. Pure lead.

Pyr.—B.B. fuses easily, coating the charcoal with a yellow oxyd, which, treated in R. F., volatilizes, giving an azure-blue tinge to the flame.

Obs.—This species is reported as occurring in globules in galena at Alstonmoor; in lava in Madeira, Rathke; at the mines near Carthagena in Spain; in Carboniferous limestone near Bristol, and at Kenmare, Ireland; according to R. P. Greg, Jr., in thin sheets in red oxyd of lead near a basaltic dyke in Ireland; in an amygdaloid near Weissig; in basaltic tufa, at Rautenberg, in Moravia; with gold in an Altai gold region, seven miles from Mt. Alatau; the gold region of Velika, southern Slavonia; near Katherinenburg, in the Urals; in the district of Zomelahuacan, in the State of Vera Cruz, in a granular limestone, containing in some places species of ammonites, in laminæ, in a foliated argentiferous galena; in the iron and manganese ore bed of Paisberg, Wermland, with hematite, magnetite, and hausmannite (B. H. Ztg., xxv. 21); also in white quartz north-west of Lake Superior, near the Dog lake of the Kaministiquia, in the form of a small string (Chapman, Can. J., 1865).

---

16. TIN. Plumbum candidum *Plin.*, xxxiv. 47. Jupiter *Alchem.* Gediegen Zinn *Germ.* Etain natif *Fr.*

Tetragonal. $1\wedge 1$, over basal edge,$=57^\circ\ 13'$, over pyramidal$=140^\circ\ 25'$, $1\text{-}i\wedge 1\text{-}i$, over basal edge,$=42^\circ\ 11'$, over pyramidal$=150^\circ\ 31'$; $a=0{\cdot}38566$ In grayish-white metallic grains.

Comp.—Tin with some lead, *Hermann*, J. pr. Ch., xxxiii. 300.

Obs.—The above angles are from artificial crystals galvanically deposited, measured by Miller. Reported as occurring with the Siberian gold; also in the Rio Tipuani valley, in Bolivia, but probably only an artificial product (D. Forbes, Phil. Mag., IV. xxix. 138, xxx. 142.)

---

17. ARSENIC. Gediegen Arsenik *Germ.* Arsenic natif *Fr.*

Rhombohedral. $R\wedge R=85^\circ\ 41'$, $O\wedge R=122^\circ\ 9'$, $a=1{\cdot}3779$. Observed forms R, $-\frac{1}{2}$, O; $-\frac{1}{2}\wedge-\frac{1}{2}=113^\circ\ 21'$. Cleavage: basal, imperfect. Often granular massive; sometimes reticulated, reniform, and stalactitic. Structure rarely columnar.

H.=3·5. G.=5·93. Lustre nearly metallic. Color and streak tin-white tarnishing soon to dark-gray. Fracture uneven and fine granular.

Comp.—Arsenic, often with some antimony, and traces of iron, silver, gold, or bismuth.

The *arsenical bismuth* of Werner (Arsenik Wismuth *Wern.*, Letztes Min.-Syst., 23, 56. 1817 *Breith.*, Char., 157, 1823, Arsenik-Glanz, Wismutischer Arsen-Glanz, *Breith.*, Char., 273, 1832), from Marienberg, is arsenic containing 3 p. c. of bismuth. H.=2; G.=5·36—5·39.

Pyr.—B.B., on charcoal volatilizes without fusing, coats the coal with white arsenous acid and affords the odor of garlic; the coating treated in R. F. volatilizes, tinging the flame blue.

Obs.—Native arsenic commonly occurs in veins in crystalline rocks and the older schists, and is often accompanied by ores of antimony, red silver ore, realgar, blende, and other metallic minerals.

The silver mines of Freiberg, Annaberg, Marienberg, and Schneeberg, afford this metal in considerable quantities; also Joachimsthal in Bohemia, Andreasberg in the Harz, Kapnik in Transylvania, Oravicza in Hungary, Kongsberg in Norway, Zmeoff in Siberia, in large masses, and at St. Maria aux Mines in Alsace; abundantly, at the silver mines at Chanarçillo, and elsewhere in Chili. In the United States it has been observed by Jackson at Haverhill, N. H., on the estate of Mr. Francis Kimball, in thin layers in dark-blue mica slate, stained by plumbago, and containing also white and magnetic pyrites; also at Jackson, N. H.; on the E. flank of Furlong Mtn., Greenwood, Me.

The name arsenic is derived from the Greek ἀρρενικόν or ἀρσενικόν, *masculine*, a term applied to orpiment or sulphuret of arsenic, on account of its potent properties.

Alt.—Oxydizes on exposure, producing a black crust, which is a mixture of arsenic and arsenolite ($\bar{A}s$), and also pure arsenolite.

17A. ANTIMONIAL ARSENIC.—An antimonial arsenic, containing, according to Schultz (Ramm. Min. Ch., 984), 7·97 p. c. of antimony, occurs at the Palmbaum mine, near Marienberg in Saxony. A similar compound, consisting, according to Genth (Am. J. Sci., II. xxxiii. 191), of arsenic 90·82 and antimony 9·18 (=17 As+1 Sb), occurs at the Comstock "lead" of the Ophir mine, Washoe Co., California, in finely crystalline, and somewhat radiated, reniform masses, between tin-white and iron-black on a fresh fracture, but grayish-black on tarnishing, associated with arsenolite, calcite, and quartz.

18. ANTIMONY. Gediget Spitsglas (fr. Sahlberg) *v. Swab.*, Ak. H. Stockh., x. 100, 1748, *Cronst.*, Min., 201, 1758. Spiesglas, Gediegen Antimon, *Germ.* Antimoine natif *Fr.*

Rhombohedral. $R \wedge R = 87° 35'$, Rose, $O \wedge R = 123° 32' \wedge a = 1·3068$. Observed planes, R, O, $\frac{1}{4}$, -2, i-2; $O \wedge \frac{1}{2}$ (cleavage plane)$=142° 58'$, $\frac{1}{2} \wedge \frac{1}{2} = 117° 7'$, $2 \wedge 2 = 89° 25'$, $\frac{1}{4} \wedge \frac{1}{4} = 144° 24'$, $O \wedge \frac{1}{4} = 159° 26'$, $O \wedge 2 = 108° 20'$. Cleavage: basal, highly perfect; $-\frac{1}{2}$ distinct. Generally massive, lamellar; sometimes botryoidal or reniform with a granular texture.

H.=3—3·5 G.=6·646—6·72,; 6·65—6·62, crystals, Kenngott. Lustre metallic. Color and streak tin-white. Very brittle.

Comp.—Antimony, containing sometimes silver, iron, or arsenic. Analysis by Klaproth (Beitr., iii. 169): from Andreasberg, Antimony 98, silver 1, iron 0·25=99·25.

Pyr.—B.B., on charcoal fuses, gives a white coating in both O. and R. F.; if the blowing be intermitted, the globule continues to glow, giving off white fumes, until it is finally crusted over with prismatic crystals of oxyd of antimony. The white coating tinges the R. F. bluish-green. Crystallizes readily from fusion.

Occurs in lamellar concretions in limestone at Sahlberg, near Sahl, in Sweden; at Andreasberg in the Harz; in argentiferous veins in gneiss at Allemont in Dauphiny; at Przibram in Bohemia; in Mexico; Huasco, Chili; Sarawak in Borneo; in argillite at South Ham, Canada; at Warren, N. J.; at Prince William antimony mine, N. Brunswick, rare.

Alt.—Oxydizes on exposure and forms Valentinite ($\bar{S}b$).

19. ALLEMONTITE. Antimoine natif arsenifère *H.*, Tr. iv. [illegible], 1822. Arsenikspiessglanz *Zippe*, Verh. Ges. Mus. Böhmen, 1824, 102. Arsenik-Antimon *Hausm.* Arseniure d' Antimoine *Fr.* Antimon-Arsen *Naum.* Arsenical Antimony, Allemontit, *Haid.*, Handb., 557, 1845

Rhombohedral. In reniform masses and amorphous; structure curved lamellar; also fine granular.

H.=3·5. G.=6·13, Thomson; 6·203, Rammelsberg. Lustre metallic, occasionally splendent; sometimes dull. Color tin-white, or reddish-gray; often tarnished brownish-black.

Comp.—$SbAs^3$=Arsenic 65·22, antimony 34·78 Analysis by Rammelsberg of the Allemont ore (1st Supp. 18): Arsenic 62·15, antimony 37·85=100, giving 1 Sb to 2·6 As.

Pyr.—B.B. emits fumes of arsenic and antimony, and fuses to a metallic globule, which takes fire and burns away, leaving oxyd of antimony on the charcoal.

Obs.—Occurs sparingly at Allemont; Przibram in Bohemia, associated with blende, antimony, spathic iron, etc.; Schladmig in Styria; Andreasberg in the Harz.

20. BISMUTH. Bisemutum, Plumbum cinereum, *Agric.*, Foss., 439, Interpr. 467. Antimonium femininum, Tectum Argenti, *Alchem.* Gediegen Wismuth *Germ.*

Hexagonal. $R \wedge R=87° 40'$, G. Rose; $O \wedge R=123° 36'$; $a=1·3035$. Observed planes, R, $-R$, O, 2, and -2; $2 \wedge 2=69° 28'$. Cleavage: basal, perfect, 2, —2, less so. Also in reticulated and arborescent shapes; foliated and granular.

H.=2—2·5. G.=9·727. Lustre metallic. Streak and color silver-white, with a reddish hue; subject to tarnish. Opaque. Fracture not observable. Sectile. Brittle when cold, but when heated somewhat malleable.

Comp. Var.—Pure bismuth, with occasional traces of arsenic, sulphur, tellurium. (1) A specimen from a gold mine of the Peak of Sorata gave Genth (Am. J. Sci., II. xxvii. 247), B 99·914, Te 0·042, Fe *tr*=99·956; and (2) Forbes (Phil. Mag, IV. xxix. 3), Bi 94·16, Te 5·09, As 0·38, S 0·07, Au *tr*=100. Forbes's mineral is much like tetradymite in foliation, and probably contains 12 to 15 p. c. of that species. (3) A fine scaly variety from Bispberg in Dalecarlia, analyzed by Clene and Feilitzen (Œfv. Ak. Stockh., 1861, 159), contains as mixture 3 to 7 p. c. of sulphid of iron.

Pyr., etc.—B.B. on charcoal fuses and entirely volatilizes, giving a coating orange-yellow while hot, and lemon-yellow on cooling. Fuses at 476° F. Dissolves in nitric acid; subsequent dilution causes a white precipitate. Crystallizes readily from fusion.

Obs.—Bismuth occurs in veins in gneiss and other crystalline rocks and clay slate, accompanying various ores of silver, cobalt, lead, and zinc. It is most abundant at the silver and cobalt mines of Saxony and Bohemia, Schneeberg, Altenberg, Joachimsthal, Johanngeorgenstadt, etc. It has also been found at Modum and Gjellebäk in Norway, and Fahlun in Sweden. At Schneeberg it forms arborescent delineations in brown jasper. At Wheal Sparnon, near Redruth, and elsewhere in Cornwall, and at Carrack Fell in Cumberland, it is associated with ores of cobalt; formerly from near Alva in Stirlingshire; in a large and rich vein at the Atlas mine, Devonshire; at San Antonio, near Copiapo, Chili; Mt. Illampa (Sorata), in Bolivia.

At Lane's mine in Monroe, Conn., it is associated in small quantities with wolfram, scheelite, galena, blende, etc., in quartz; occurs also at Brewer's mine, Chesterfield district, South Carolina.

---

21. TELLURIUM. Aurum paradoxum vel problematicum *Müller v. Reichenstein*, Phys. Arb Wien, i. 1782. Sylvanite *Kirwan*, Min., ii. 324, 1796. Gediegen-Tellur *Klapr.*, Beitr., iii. 2, 1802 Gediegen Sylvan *Germ.* Tellure natif auro-ferrifère *H.*

Hexagonal. $R \wedge R=86° 57'$, G. Rose; $O \wedge R=123° 4'$, a 1·3302. Observed planes, R, $-R$, I, O; $R \wedge -R$, over base, =113° 52'. In six-sided prisms, with basal edges replaced. Cleavage: lateral perfect, basal imperfect. Commonly massive and granular.

H.=2—2·5. G.=6·1—6·3. Lustre metallic. Color and streak tin white. Brittle.

Comp.—According to Klaproth (l. c.), Tellurium 92·55, iron 7·20, and gold 0·25. A specimen from Nagyag afforded Petz (Pogg., lvii. 447), Tellurium 97·215, and gold 2·785, with a trace of iron and sulphur.

Pyr.—In the open tube fuses, giving a white sublimate of tellurous acid, which B. B. fuses to colorless transparent drops. On charcoal fuses, volatilizes almost entirely, tinges the flame green, and gives a white coating of tellurous acid.

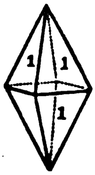
Obs.—Native tellurium occurs at the mine of Maria Loretto, near Zalathna, in Transylvania (whence the name *Sylvan* and *Sylvanite*), in sandstone, accompanying quartz, iron pyrites, and gold. About forty years since it was found in considerable abundance, and was melted to extract the small quantity of gold it contains.

22. NATIVE SULPHUR. Natürlicher Schwefel *Germ.* Soufre *Fr.*

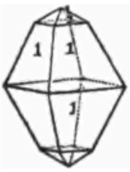
Orthorhombic. $I \wedge I = 101° 46'$, $O \wedge 1\text{-}\bar{i} = 113° 6'$; $a : b : c = 2·344 : 1 : 1·23$. Observed planes : O; vertical, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\breve{2}$, $i\text{-}\breve{3}$; domes, $1\text{-}\bar{i}$, $\frac{1}{3}\text{-}\bar{i}$, $\frac{1}{4}\text{-}\bar{i}$, $1\text{-}\breve{i}$, $\frac{2}{3}\text{-}\breve{i}$, $\frac{1}{3}\text{-}\breve{i}$; octahedral, 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{5}$, $1\text{-}\breve{3}$, $\frac{1}{3}\text{-}\breve{3}$.

$O \wedge \frac{1}{3} = 134° 47'$	$O \wedge 1\text{-}\breve{3} = 115° 53'$	$1 \wedge 1$, mac., $= 106° 25'$
$O \wedge \frac{1}{2} = 123\ \ 30$	$O \wedge 1\text{-}\breve{i} = 117\ \ 41$	$1 \wedge 1$, brach., $= 85\ \ 07$
$O \wedge 1 = 108\ \ 19$	$O \wedge \frac{2}{3}\text{-}\breve{i} = 128\ \ 12$	$1 \wedge 1$, bas., $= 143\ \ 23$

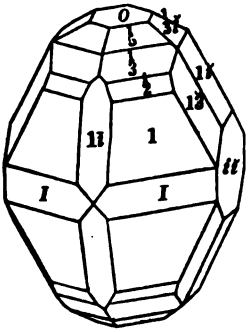
55.



56.



57.



Cleavage: I, and 1, imperfect. Twins, composition-face, I, sometimes producing cruciform crystals. Also massive, sometimes consisting of concentric coats.

H.=1·5–2·5. G.=2·072, of crystals from Spain. Lustre resinous. Streak sulphur-yellow, sometimes reddish or greenish. Transparent—subtranslucent. Fracture conchoidal, more or less perfect. Sectile.

Comp.—Pure sulphur; but often contaminated with clay or bitumen.

Pyr., etc.—Burns at a low temperature with a bluish flame, with the strong odor of sulphurous acid. Becomes resinously electrified by friction. Insoluble in water, and not acted on by the acids.

Obs.—Sulphur is dimorphous, the crystals being obtuse oblique rhombic prisms, of 90° 32′, and inclination of the vertical axis=95° 46′, when formed at a moderately high temperature (125° C., according to Frankenheim).

The great repositories of sulphur are either beds of gypsum and the associate rocks, or the regions of active and extinct volcanoes. In the valley of Noto and Mazzaro, in Sicily; at Conil, near Cadiz, in Spain; Bex, in Switzerland; Cracow, in Poland, it occurs in the former situation; near Bologna, Italy, in fine crystals, imbedded in bitumen. Sicily and the neighboring volcanic isles; the Solfatara, near Naples; the volcanoes of the Pacific ocean, etc., are localities of the latter kind. The crystals from Sicily are sometimes two or three inches in diameter. It is also deposited from hot springs in Iceland; and in Savoy, Switzerland, Hanover, and other countries, it is met with in certain metallic veins; near Cracow and in Upper Egypt there are large deposits. A fibrous variety is found near Siena, in Tuscany. Abundant in the Chilian Andes.

Sulphur is found near the sulphur springs of New York, Virginia, etc., sparingly; in many coal deposits and elsewhere, where sulphid of iron is undergoing decomposition; in microscopic crystals at some of the gold mines of Virginia and North Carolina; as a powder and in crystals in the Western lead regions, in cavities in the limestone; in minute crystals on cleavage surfaces of galena, Wheatley mine, Phenixville, Pa.; in small masses in limestone on the Potomac, twenty-five miles above Washington; in California, at the geysers of Napa valley, Sonoma Co.; in Santa Barbara in good crystals; near Clear lake, Lake Co., a large deposit, with a vein of cinnabar (now worked) cutting through it; in Nevada, in Humboldt Co., in large beds; Nye and Esmeralda Cos., 12 m N. of Silver Peak; Washoe Co.

The sulphur mines of Sicily, the crater of Vulcano, the Solfatara near Naples, and the beds of California, afford large quantities of sulphur for commerce. It is also obtained in roasting the sulphids of iron and copper.

This species is homœomorphous with barytes and marcasite if $\frac{3}{2}$-*i* be taken as the unit macrodome. The above figure, 57, is by Scacchi of Naples.

23. SELENSULPHUR. Selenschwefel *Stromeyer*, Schw. J., xliii. 453.

Resembling sulphur, but of an orange or brownish color.

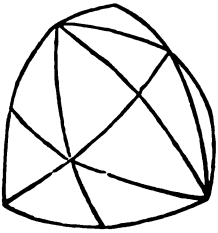
B.B. on charcoal burns readily, yields fumes of selenium and sulphurous acid. From Vulcano, one of the Lipari islands, mixed with sulphur. Also observed by the author at Kilauea, Hawaii

---

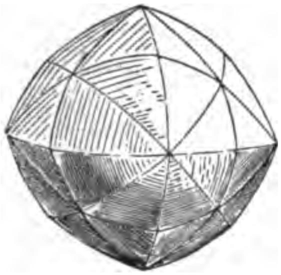
24. DIAMOND. Adamas, punctum lapidis, pretiosior auro, *Manilius*, Astron., iv. l. 926 (the earliest distinct mention of true Diamond). Adamas, in part, *Plin.*, xxxvii. 15. Demant *Germ.* Diamant *Fr.*

Isometric. Observed planes, 1, 2, *I*, *O*, 3-$\frac{3}{2}$, *i*-$\frac{3}{2}$, *i*-$\frac{4}{3}$; often tetrahedral in planes 1, 2, and 3-$\frac{3}{2}$. Figs 1, 2, 3, 5, 6, 8, 24, 25, 27; also *i*-$\frac{4}{3}$, similar to f. 16 and 17; also f. 40, all usually with curved faces, as in f. 58 (=27), 59 (=39), 60, the planes of which are 3-$\frac{3}{2}$; 60 is a distorted form of 58. Cleavage: octahedral, highly perfect. Twins; composition-face, octahedral, as in fig. 50, but with curved faces; f. 61, which is an elliptic twin of 58, the middle portion between two opposite sets of six planes being wanting; f. 63, in which composition is parallel to the octahedral faces, but the form corresponds to two interpenetrating tetrahedrons, as illustrated in f. 62. Rarely massive.

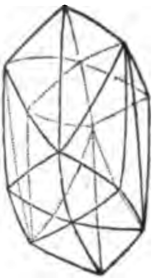
59.



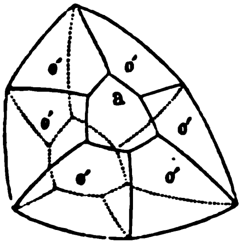
58.



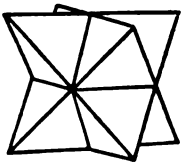
60.



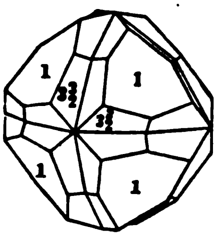
61.



62.



63.



H.=10. G.=3·5295, Thomson; 3·55, Pelouze. Lustre brilliant adamantine. Color white or colorless: occasionally tinged yellow, red, orange, green, blue, brown, sometimes black. Transparent; translucent when dark colored. Fracture conchoidal. Index of refraction 2·439. Exhibits vitreous electricity when rubbed.

Comp.—Pure carbon, isometric in crystallization.

Var.—1. *Ordinary*, or crystallized. The crystals often contain numerous microscopic cavities, as detected by Brewster, and some are rendered nearly black by their number; and around these cavities the diamond shows evidence, by polarized light, of compression, as if from pressure in the included gas when the diamond was crystallized. Sometimes crystals bear impressions of other crystals. The back planes of diamonds reflect all the light that strikes them at an angle exceeding 24° 13′, and hence comes the peculiar brilliancy of the gem. The refraction of light by the diamond is often irregular, probably arising from the cause which has produced the convex forms. In some plates from crystals, Descloizeaux has observed a fixed star of six symmetrical rays, and in others, allied in character, the rays were replaced by three large elliptical areas. Descloizeaux shows that the rays are symmetrical with reference to the faces of the octahedron.

2. *Massive.* In black pebbles or masses, called *carbonado*, occasionally 1,000 carats in weight. H.=10; G.=3·012—3·416. Consist of pure carbon, excepting 0·27 to 2·07 p. c.

3. *Anthracitic; Carbon diamantaire*, Count de Douhet, Les Mondes, Ap. 11, 1867. Like anthracite, but hard enough to scratch even the diamond. In globules or mammillary masses, consisting partly of concentric layers; fragile; G.=1·66; composition, Carbon 97, hydrogen 0·5, oxygen 1·5. Cut in facets and polished, it refracts and disperses light, with the white lustre peculiar to the diamond. Locality unknown, but supposed to come from Brazil. C. Mène has observed that an anthracite from Creuzot, consisting of C 98·2, O 0·04, ash 0·12, long heated in pieces in a crucible, takes a metallic lustre, and will then cut glass like a diamond. As anthracite is derived from bituminous coal, by subjection to more or less heat under pressure, it is possible that the degree or condition of heating may produce an anthracite with its particles partly or wholly of the nature of the diamond, and still have the low specific gravity of anthracite.

Pyr., etc.—Burns, and is wholly consumed at a temperature of 14° Wedgewood, producing carbonic acid gas. It is not acted on by acids or alkalies.

Obs.—The diamond appears generally to occur in regions that afford a laminated granular quartz rock, called *itacolumite*, which pertains to the talcose series, and which in thin slabs is more or less flexible. This rock is found at the mines of Brazil and the Urals; and also in Georgia and North Carolina, where a few diamonds have been found. It has also been detected in a species of conglomerate, composed of rounded siliceous pebbles, quartz, chalcedony, etc., cemented by a kind of ferruginous clay. Diamonds are usually, however, washed out from the soil. According to M. Denis (Ann. des M., III. xix. 602) the diamond in Minas Geraes, Brazil, is found in two different deposits; one called *gurgulho*, consisting of broken quartz, and covered by a thin bed of sand or earth; the other, *cascalho*, of *rolled* quartz pebbles, united by a ferruginous clay, resting usually on talcose clays, the whole the debris from talcose rocks. The first deposit affords the finest diamonds, and both contain also gold, platinum, magnetic iron, rutile, etc. The most celebrated mines are on the rivers Jequitinhonha and Pardo, north of Rio Janeiro, where the sands (the waters being turned off) are washed by slaves. It has lately been found in Bahia, on the river Cachoeira, at the mines of Surua and Sincora; and Damour has recognized in the sand of the locality, quartz, feldspar, rutile, brookite, anatase, zircon, diaspore, magnetic iron, gold in grains, anhydrous phosphate of alumina and lime, a silicate of yttria, and a hydro-phosphate of yttria. At Bogagem, Minas Geraes, an enormous diamond of 254½ carats has been found; it was a dodecahedron, with beveled edges, in which there were impressions of other diamond crystals, showing that it was originally one of a cluster; it weighs, since cutting, 122 to 125 carats, and is called the "Star of the South." The Brazilian mines were first opened in 1727, and it is estimated that since then they have yielded two tons of diamonds.

The Ural diamonds occur in the detritus along the Adolfskoi rivulet, where worked for gold, and also at other places.

In India the diamond is met with at Purteal, between Hyderabad and Masulipatam, where the famous Kohinoor was found; but there are now only two places of exploration, and these are let to some of the natives for less than 25 francs a year; and if the hands find a stone worth four or five rupees ($2 to $2½) a month, they consider themselves fortunate. To such a state are the famous mines of Golconda now reduced. They are obtained also near Parma in Bundelcund, where some of the most magnificent specimens have been found; also on the Mahanuddy near Ellore. The locality on Borneo is at Pontiana, on the west side of the Ratoos mountain. The river Gunil, in the province of Constantine in Africa, is reported to have afforded some diamonds.

In the United States a few crystals have been met with in Rutherford Co., N. C., and Hall Co.

Ga (Am. J. Sci. II. ii. 253, and xv. 373); they occur also at Portis mine, Franklin Co., N. C. (Genth); one handsome one, over ½ in. in diameter, in the village of Manchester, opposite Richmond, Va.

In California, at Cherokee ravine, in Butte Co.; also in N. San Juan, Nevada Co.; in French Corral, one of 1⅓ carats; at Forest Hill, El Dorado Co., of 1⅛ carats; Fiddletown, Amador Co.; near Placerville. Reported from Idaho.

In Australia, in the valley of the Turon; in the bed of the Macquarie; mouth of Pyramul Creek; on Calcula Creek; and also in Victoria; also in West Australia, at Freemautle.

In Brazil the diamond has been found massive, in small black pebbles, called *carbonado*, having the specific gravity 3·012—3·416. They proved on trial to be pure carbon excepting 2·07 to 0·27 per cent. This compact diamond is sold in the region at 75 cents the carat of three and one-sixth grains troy, and the masses are sometimes 1,000 carats in weight.

Brewster finds that diamonds contain generally numerous microscopic cavities, and some are rendered nearly black by their number; and around these cavities the diamond shows evidence of compression, as if from pressure in the included gas when the diamond was crystallizing. Diamonds have been observed having impressions of other crystals.

The largest diamond of which we have any knowledge is mentioned by Tavernier as in possession of the Great Mogul. It weighed originally 900 carats, or 2769·3 grains, but was reduced by cutting to 861 grains. It has the form and size of half a hen's egg. It was found in 1550 in the mine of Colone. The Pitt or Regent diamond weighs but 136·25 carats, or 419¼ grains; but is of unblemished transparency and color. It is cut in the form of a brilliant, and is estimated at £125,000. The Kohinoor measured, on its arrival in England, about 1½ inches in its greatest diameter, over ½ of an inch in thickness, and weighed $186\frac{1}{16}$ carats, and was cut with many facets. It has since been recut, and reduced to a diameter of $1\frac{7}{16}$ by 1⅜ nearly, and thus diminished over one-third in weight. It is supposed by Mr. Tennant to have been originally a dodecahedron, and he suggests that the great Russian diamond and another large slab weighing 130 carats were actually cut from the original dodecahedron. Tavernier gives the original weight at 787½ carats. The Rajah of Mattan has in his possession a diamond from Borneo, weighing 367 carats. The mines of Brazil were not known to afford diamonds till the commencement of the 18th century.

Colorless diamonds are in general most highly esteemed. When cut and polished, a diamond of the purest water in England, weighing one carat, is valued at £12; and the value of others is calculated by multiplying the square of the weight in carats by 12, except for those exceeding 20 carats, the value of which increases at a much more rapid rate. This rule is scarcely regarded in market, as the standard of purity and taste for different countries differs, and the slightest tinge of color affects greatly the commercial value. Blue is an exceedingly rare color; and one of this shade, the Hope diamond, weighing only 4½ carats, but of peculiar beauty and brilliancy, is valued at £25,000. A yellowish diamond of large size (value £12,000) has been found by Fremy to take a rose-red color when heated, which color it retains for two or three days, and then resumes the original yellow. An emerald-green diamond in the Dresden Treasury weighs 31½ carats.

The ancient Romans had rings set with the diamond, and used the chippings for arming gravers' tools. Pliny speaks of the six-angled form of the crystals of the *adamas*, and their resemblance to two pyramids or tops placed base to base, a description that would apply, perhaps, as well to a double hexagonal pyramid as to an octahedron; yet it is probable, from the other characters mentioned, the hardness, rarity, small size, use, and occurrence in gold regions, that the octahedral diamond was referred to. The adamas of the ancients included some corundum and other hard stones, and even hard metal. Theophrastus makes no mention of the true diamond. (See, on the *adamas* of the ancients, King on Precious Stones and Gems, p. 19.)

The method of polishing diamonds was discovered in 1456, by Louis Berquen, a citizen of Bruges, previous to which time the diamond was known in Europe only in its uncut state. It appears to have been practised long before in India, the faceting of the Kohinoor dating far back into uncertain time. (See King, pp 30, 31.)

The diamond has probably proceeded, like mineral coal and oil, from the slow decomposition of vegetable material, or even from animal matters, either source affording the requisite carbon; but it has been formed under those conditions as to heat that has produced the metamorphism of argillaceous and arenaceous schists and their auriferous quartz veins; since it is found exclusively in gold regions, or in the sands derived from gold-bearing rocks. The schists that were altered at the time may have previously been shales impregnated with petroleum, or other carbonaceous substances (hydrocarburets) of organic origin. Chancourtois observes that the formation from a hydrocarburetted vapor or gas is analogous to that of sulphur from hydrosulphuretted emanations. In the oxydation of the latter by the humid process, the hydrogen becomes oxydized, and only a part of the sulphur changes to sulphurous acid, the rest remaining as sulphur. So in the humid oxydation of a carburetted hydrogen, the hydrogen is oxydized, part of the carbon becomes carbonic acid, and the rest remains as carbon and may form crystallized diamond.

25. GRAPHITE. Plumbago, Molybdæna, Bly-Ertz, *Bromell*, Min., 58, 1739 [not Plumbago *Agric.*, *Gesner*]. Blyertz pt, Mica pictoria nigra, Molybdæna pt., *Wall.*, 131, 1747. Mica des Peintres, Crayon, *Fr. Trl.* Wall., 1753. Black Lead. Reissbley (=Drawing-lead) *Germ.* Molybdænum *Linn.*, 1768. Plumbago *Scheele* (proving its carbon nature), Ak. H. Stockholm, 1779. Plombagine *de Lisle*, Crist., 1783. Graphit *Wern.*, Bergm. J., 380, 1789, *Karst.*, Mus. Lesk., ii 339, 1789. Carburet of Iron. Fer carburé *Fr.*

Hexagonal. In flat six-sided tables. $R \wedge R = 85° \; 29'$, Kenngott, by calculation from Ticonderoga crystals, which have the planes $2R$, $\frac{2}{3}$-2 and 2-2, with, approximately, $O \wedge \frac{2}{3}\text{-}2 = 137°$, $O \wedge 2 = 110°$, and $O \wedge 2 = 122°$. A plane, observed by Haidinger, is probably $\frac{1}{4}R$, or $\frac{1}{4}$-2; the angle measured, 40° 56′, was the basal angle of the pyramid. The basal planes (O) are often striated parallel to the alternate edges. Cleavage: basal, perfect. Commonly in imbedded, foliated, or granular masses. Rarely in globular concretions radiated in structure.

H.=1—2. G.=2·0891; of Ticonderoga, 2·229 Kenngott; 2·14 Wunsiedel, Fuchs. Lustre metallic. Streak black and shining. Color iron-black—dark steel-gray. Opaque. Sectile; soils paper, Thin laminæ flexible. Feel greasy.

Var.—(*a*) Foliated; (*b*) columnar, and sometimes radiated; (*c*) scaly, massive, and slaty (*d*) granular massive; (*e*) earthy, amorphous, without metallic lustre except in the streak; (*f*) in radiated concretions.

Comp.—Pure carbon, with often a little oxyd of iron mechanically mixed. Scheele (1779, l. c.) and some later chemists made the iron essential, and the species a carburet of iron. Vanuxem in 1825 (J. Ac. Philad., v. 21) showed that the iron was an oxyd, and unessential. He obtained from the graphite of Bustletown, Pa., Carbon 94·4, ox. iron and manganese 1·4, silica 2·6, $\dot{H}$ 0·6=99. Fuchs found (J. pr. Ch., vii. 253) only 0·33 p. c. of ash (or impurities) in that of Wunsiedel, a pure black, amorphous, unmetallic kind, metallic in streak, having G.=2·14; Fritzsche (B. H. Ztg., 323, 1854) 0·9 in that of Ceylon.

The following are analyses of different graphites by C. Mène (C. R., lxiv. 1091, 1867):

	G.	Carbon	Vol.	Ash	Comp. of 100 parts of ash. $\ddot{Si}$	$\bar{\bar{Al}}$	$\dot{Fe}$	$\dot{Mg}$,$\dot{Ca}$	Alk. & loss.

In the G. of Mariinskoi, v. Jevreinof found (Russ. B. J. 1849) C 94·77, ash 5·22 (=$\ddot{\text{Si}}$ 2·04, $\dddot{\text{Fe}}$ 1·83, $\dddot{\text{Al}}$ 0·88, $\dot{\text{Mg}}$, $\dot{\text{Ca}}$ 0·17); v. Laskovsky found (Bull. Soc. Nat. Mosc. 1856) in a plumose var. C 83·755, ash 15·111, water 0·888; v. Pusirevski found (Verh. Min. Ges. St. Pet. 1857, 1858) C 84·08, $\ddot{\text{Si}}$ 10·98, $\dot{\text{H}}$ 3·77, with some $\dddot{\text{Fe}}$, $\dot{\text{Ca}}$, $\ddot{\text{Mn}}$, and G.=2·26—2·31. In G. of the Kirghiz Steppe, Hermann found C 40·55, earthy matters 56·56, $\dot{\text{H}}$ 2·89=100. These results show that the variations arising from impurities are great. The material analyzed by Wheeler is that used by the firm of A. W. Faber.

Tremenheerite, Piddington, appears to be impure graphite, or is between coal and graphite; it is scaly in structure, and highly metallic in lustre. It afforded Piddington Carbon 85·70, water and sulphur 4·00, sesquioxyd of iron 2·50, earthy impurities, chiefly silica, 7·50, water and loss 0·30=100; the iron occurs as sulphuret. *Tenasserim*, Rev. F. Mason, Maulmain, 1852, p. 52.

Pyr., etc.—At a high temperature it burns without flame or smoke, leaving usually some red oxyd of iron. B.B. infusible; fused with nitre in a platinum spoon, deflagrates, converting the reagent into carbonate of potash, which effervesces with acids. Unaltered by acids.

Obs.—Graphite occurs in beds and imbedded masses, laminæ, or scales, in granite, gneiss, mica schist, crystalline limestone. It is in some places a result of the alteration by heat of the coal of the coal formation. Sometimes met with in greenstone. It is a common furnace product.

A fine variety of graphite occurs at Borrowdale in Cumberland, in nests in trap, which occurs in clay slate; in Glenstrathfarrar in Invernesshire, forms nests in gneiss; at Arendal in Norway, in quartz; at Pargas in Finland; in the Urals, Siberia, Finland; in various parts of Austria; Prussia; France; at Craigman in Ayrshire, it occurs in coal beds, which have been altered by contact with trap. In Irkutsk, in the Tunkinsk mts., at the very valuable Mariinskoi graphite mine, a large mass has been obtained, having the structure of the wood from which it was formed. Large quantities are brought from the East Indies.

Forms beds in gneiss, at Sturbridge, Mass., where it presents a structure between scaly and fine granular, and an occasional approximation to distinct crystallizations; also at North Brookfield, Brimfield, and Hinsdale, Mass.; extensively in Cornwall, near the Housatonic, and in Ashford, Conn.; also in Brandon, Vt.; at Grenville, C. E., associated with sphene and tabular spar in granular limestone. Foliated graphite occurs in large quantities at Ticonderoga, on Lake George; also upon Roger's Rock, associated with pyroxene and sphene. Near Amity, Orange Co., N. Y., it is met with in white limestone, accompanying spinel, chondrodite, hornblende, etc.; at Rossie, St. Lawrence Co., N. Y., with iron ore, and in gneiss; in Franklin, N. J., in rounded concretions radiated within; in Wake, N. C.; on Tyger River, and at Spartenburgh near the Cowpens Furnace, S. C.; also in Bucks Co., Penn., three miles from Attleboro', associated with tabular spar, pyroxene, and scapolite; and one and a half miles from this locality, it occurs in abundance in syenite, at Mansell's black lead mine. There is a large deposit at St. John, New Brunswick.

In the United States, the mines of Sturbridge, Mass., of Ticonderoga and Fishkill, N. Y., of Brandon, Vt., and of Wake, N. C., are worked; and that of Ashford, Conn., formerly afforded a large amount of graphite.

The name *black lead*, applied to this species, is inappropriate, as it contains no lead. The name graphite, of Werner, is derived from γράφω, *I write*.

Nordenskiöld makes the graphite of Ersby and Storgard *monoclinic*, with the inclination of the vertical axis 88° 14′, *i-i* (cleavage face) on faces of oblique prism=106° 21′, and angle of prism 122° 24′ (Pogg., xcvi. 110).

II. SULPHIDS, TELLURIDS, SELENIDS, ARSENIDS, ANTIMONIDS, BISMUTHIDS.

There are three natural divisions of the species of this section:

1. Simple Sulphids and Tellurids of Metals of the Sulphur or Arsenic Group.

2. Simple Sulphids, Tellurids, Selenids, Arsenids, Antimonids, Bismuthids, of Metals of the Gold, Iron, and Tin Groups. Some of the species contain, along with sulphur, also arsenic, antimony, or bismuth; but the arsenic, antimony, or bismuth, in such cases, replaces sulphur as its isomorph.

3. Double Sulphids: or Sulpharsenites, Sulphantimonites, Sulphobismuthites.

In this section of Sulphids, etc., the atomic weights of *arsenic*, *antimony* and *bismuth* are taken at half the value given in the table on page xvi, as it is in this state that they approximate to sulphur in the forms and relations of their compounds. The atomic weights thus halved are, for arsenic 37·5, antimony 61, bismuth 105; that of sulphur being 16.

---

1. SIMPLE SULPHIDS AND TELLURIDS OF METALS OF THE SULPHUR AND ARSENIC GROUPS.

1. **REALGAR GROUP.** Composition RS. Crystallization Monoclinic.

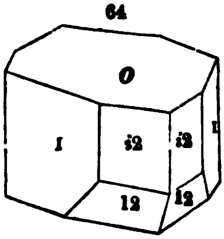
$\frac{1}{2}$-ì					$\frac{1}{2}$-2				

Observed planes.

64



H.=1·5—2. G.=3·4—3·6. Lustre resinous. Color aurora-red or orange-yellow. Streak varying from orange-red to aurora-red. Transparent—translucent. Fracture conchoidal, uneven.

Comp.—As S=Sulphur 29·9, arsenic 70·1=100. A specimen from Pola de Lena in Asturia, Spain, gave Hugo Müller (J. Ch. Soc., xi. 242) S 30·00, As 70·25.

Pyr., etc.—In the closed tube melts, volatilizes, and gives a transparent red sublimate; in the open tube, sulphurous fumes, and a white crystalline sublimate of arsenous acid. B.B. on charcoal burns with a blue flame, emitting arsenical and sulphurous odors. Soluble in caustic alkalies.

Obs.—Occurs with ores of silver and lead, at Felsobanya in Upper Hungary, at Kapnik and Nagyag in Transylvania, at Joachimsthal in Bohemia, at Schneeberg in Saxony, at Andreasberg in the Harz; at Tajowa in Hungary, in beds of clay; at Binnenthal, Switzerland, in dolomite; at Wiesloch in Baden, in the Muschelkalk; near Julamerk in Koordistan; in Vesuvian lavas, in minute crystals. Strabo speaks of a mine of *sandaraca* (the ancient name of this species) at Pompeiopolis in Paphlagonia.

For recent crystallographic observations see Hessenberg's Min. Notizen, Nos. 1 and 3.

The name *realgar* is of Arabic origin.

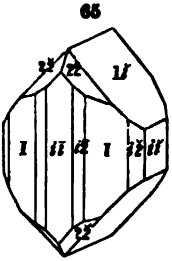
Alt.—Changes, on exposure, to orpiment ($As^2 S^3$) and arsenolite ($As^2 O^3$), 6 of As S becoming 2 $As^2 S^3$, and 2 As being set free which changes to $As^2 O^3$ or arsenolite (Volger). A black crust sometimes forms on realgar, which is supposed by Volger to be a sulphid containing less sulphur than realgar.

27. **ORPIMENT.** 'Αῤῥενικόν *Theophr.* 'Αρσενικόν *Dioscor.* Auripigmentum, Arrhenicum, *Plin.*, xxxiii. 22, xxxiv. 56. Auripigmentum, *Germ.* Operment, *Agric.*, Interpr., 463. 1546. Orpiment. Rauschgelb pt., Risigallum pt., Arsenicum flavum, *Wall.*, 224, 1747. Arsenic jaune *Fr.* *trl.* Wall., i 406, 1753. Gelbes Rauschgelb *Germ.* Arsenic sulfuré jaune *Fr.* Yellow sulphuret of Arsenic.

Orthorhombic. $I \wedge I=100° 40'$, $O \wedge 1\text{-}\bar{i}=126° 30'$; $a : b : c=1·3511 : 1 : 1·2059$. Observed planes as in the annexed figure.

O ∧ 1-ĭ=131° 45′ i-2̆ ∧ i-2̆ ov. i-ĭ=117° 49′ 1-ĭ ∧ 1-ĭ=83° 30′
O ∧ 2-2̆=127 27 2-2̆ ∧ 2-2̆ adj. = 94 20 2-2̆ ∧ 2-2̆ ov. 1-ĭ=131 36

65



Cleavage: i-ī highly perfect, i-ĭ in traces. i-ī longitudinally striated. Also, massive, foliated, or columnar; sometimes reniform.

H. = 1·5 – 2. G. = 3·48, Haidinger; 3·4, Breithaupt. Lustre pearly upon the faces of perfect cleavage; elsewhere resinous. Color several shades of lemon-yellow. Streak yellow, commonly a little paler than the color. Subtransparent—subtranslucent. Sub-sectile. Thin laminæ obtained by cleavage flexible but not elastic

Comp.—$As^2 S^3$=Sulphur 39, arsenic 61=100.

Pyr., etc.—In the closed tube, fuses, volatilizes, and gives a dark yellow sublimate; other reactions the same as under realgar. Dissolves in nitromuriatic acid and caustic alkalies.

Obs.—Orpiment in small crystals is imbedded in clay at Tajowa, near Neusohl in Upper Hungary. It is usually in foliated and fibrous masses, and in this form is found at Kapnik in Transylvania, at Moldawa in the Bannat, and at Felsobanya in Upper Hungary, where it exists in metalliferous veins, associated with realgar and native arsenic; at Hall in the Tyrol it is found in gypsum; at St. Gothard in dolomite; at the Solfatara near Naples, it is the result of volcanic sublimation; in Fohnsdorf, Styria, found in brown coal. Near Julamerk in Koordistan, there is a large Turkish mine. Occurs also at Acobambillo, Peru. Small traces are met with in Edenville, Orange Co., N. Y., on arsenical iron.

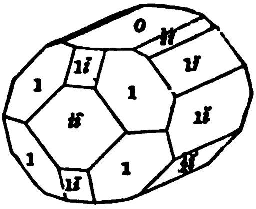
The name orpiment is a corruption of its Latin name auripigmentum, "*golden paint*," which was given in allusion to the color, and also because the substance was supposed to contain gold.

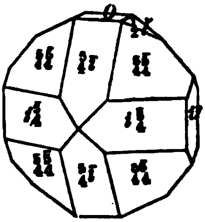
The crystalline form is made *monoclinic* by Breithaupt (B. H. Ztg., xxv. 194). He makes i-ī the clinodiagonal plane, and i-ĭ the front or orthodiagonal, with the planes i-ĭ, above and below i-ĭ, hemidomes, inclined at unequal angles on i-ĭ, that below at an angle 2° to 3° the smaller. Also, he makes i-2̆ the plane I. No definite measurements are given.

28. DIMORPHITE. Dimorfina *Scacchi*, Mem. Geol. sulla Campania, Napoli, 116, 1849.

Orthorhombic. Two types: (A), I ∧ I = 98° 6′, O ∧ 1-ī = 127° 50′; a : b : c=1·2876 : 1 : 1·1526; (B) common form, I ∧ I=100° 32′, O ∧ 1-ī=127° 1′; a : b : c = 1·3262 : 1 : 1·203. Observed planes as in the annexed figures.

66 67





In A, O ∧ 1 = 120° 23′, O ∧ 1-ĭ =131° 50′, O ∧ ½-ĭ = 150° 49′ 1-ĭ ∧ 1-ĭ over O = 83° 40′, 1 ∧ 1 ov. 1-ĭ=111° 10′.

In B, O ∧ ¼-ī=121° 6′, O ∧ ½-ĭ =151° 7′, O ∧ ¼-¾=116° 40′, i-¾ ∧ i-¾=112° 45′. Cleavage none. Crystals minute.

H.=1·5. G.=3·58. Lustre splendent adamantine. Color orange-yellow: powder saffron-yellow. Translucent and transparent. Fragile.

Comp.—From imperfect trials by Scacchi, perhaps $As^4 S^3$=Sulphur 24·55, arsenic 75·45=100.

Pyr., etc.—Heated in a porcelain crucible with a spirit lamp, affords odorous fumes and becomes red; with more heat becomes brown, gives off yellow fumes, and evaporates, leaving no residue; with soda a garlic odor. Completely soluble in nitric acid.

Obs.—From a fumarole of the Solfatara, Phlegræan fields. Crystals not over half a millimeter in their longest direction.

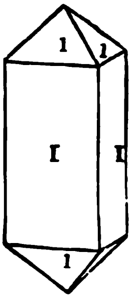
69. STIBNITE. Στίμμι, Στίβι, Πλατυόφθαλμον, *Dioscor.* Stimmi, Stibi, Stibium, *Plin.*, xxxiii. 33, 34. Stibi, Spiessglas, *Basil Valentine* (who proved it to contain sulphur), 1430. Lupus metallorum *Alchem.* Spiess-Glass-Erz *Brückmann*, Berkwerke, 1727. Spitsglasmalm, Minera Antimonii, Antimonium Sulphure mineralisatum, *Wall.*, 237, 1747. Grauspiessglaserz, Grauspiessglanzerz, Antimonglanz, *Germ.* Antimoine sulfuré *Fr.* Sulphuret of Antimony; Gray Antimony; Antimony Glance. Stibine *Beud.*, Tr., ii. 421, 1832. Antimonit *Haid.*, Handb., 568, 1845. Stibnite *Dana*, Min., 1854.

Orthorhombic. $I \wedge I = 90° \ 54'$, $O \wedge 1\text{-}\bar{\imath} = 134° \ 16'$; $a : b : c = 1·0259 : 1 : 1·0158$. Observed planes: O; vertical I, $i\text{-}\breve{\imath}$, $i\text{-}\bar{\imath}$, $i\text{-}\frac{4}{3}$, $i\text{-}\frac{3}{2}$, $i\text{-}\frac{5}{3}$, $i\text{-}\breve{2}$, $i\text{-}\breve{3}$, $i\text{-}\breve{4}$, $i\text{-}\breve{5}$, $i\text{-}\frac{4}{3}$, $i\text{-}\bar{2}$, $i\text{-}\bar{3}$; domes, $\frac{1}{6}\text{-}\bar{\imath}$, $\frac{1}{3}\text{-}\bar{\imath}$, $\frac{1}{2}\text{-}\bar{\imath}$, $1\text{-}\bar{\imath}$, $\frac{1}{3}\text{-}\breve{\imath}$, $\frac{1}{2}\text{-}\breve{\imath}$, $\frac{2}{3}\text{-}\breve{\imath}$, $1\text{-}\breve{\imath}$, $\frac{4}{3}\text{-}\breve{\imath}$, $\frac{5}{3}\text{-}\breve{\imath}$, $3\text{-}\breve{\imath}$; octahedrons, $\frac{1}{3}$, $\frac{1}{2}$, 1, 3; $1\text{-}\frac{5}{4}$, $1\text{-}\frac{4}{3}$, $1\text{-}\frac{8}{7}$, $1\text{-}\frac{4}{3}$, $1\text{-}\frac{8}{7}$, $\frac{1}{2}\text{-}\breve{2}$, $\frac{2}{3}\text{-}\breve{2}$, $\frac{4}{3}\text{-}\breve{4}$, $\frac{8}{3}\text{-}\breve{2}$, $2\text{-}\breve{2}$, $6\text{-}\breve{2}$, $3\text{-}\breve{3}$, $\frac{8}{3}\text{-}\breve{4}$, $\frac{4}{3}\text{-}4$. Krenner.

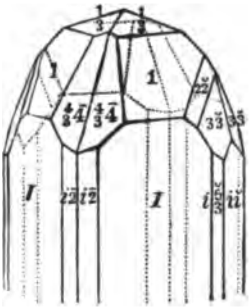
$O \wedge \frac{1}{3} = 154° \ 20'$.	$O \wedge 1\text{-}\breve{\imath} = 134° \ 42'\frac{1}{2}$.	$O \wedge 1 = 124° \ 45'$.
$O \wedge 1 = 124 \ \ 45$	$i\text{-}\breve{2} \wedge i\text{-}\breve{2}$, mac., $= 127 \ \ 36$	$1 \wedge 1$, brach., $= 108 \ \ 40$
$O \wedge 2\text{-}\breve{2} = 113 \ \ 49$	$1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath}$, top, $= 89 \ \ 24$	$1 \wedge 1$, bas., $= 110 \ \ 30$

Lateral planes deeply striated longitudinally. Cleavage: $i\text{-}\breve{\imath}$ highly perfect. Often columnar, coarse or fine; also granular to impalpable. H.=2. G.=4·516, Haüy; 4·62, Mohs. Lustre metallic. Color and streak lead-gray, inclining to steel-gray: subject to blackish tarnish, sometimes iridescent. Fracture small sub-conchoidal. Sectile. Thin laminæ a little flexible.

68



69



Comp.—$Sb^2 S^3$=Sulphur 28·2, antimony 71·8=100. Bergmann, who made the first determination of the sulphur in the mineral (Opusc., ii. 167, 1782), obtained S 26, Sb 74=100. Eight analyses of stibnite from Arnsberg, Westphalia, gave Schneider a mean of Sb 71·48, S 28·52, excluding 0·38 p. c. of quartz; the results of the analyses varied from 71·441 to 71·519 (Pogg., xcviii. 293). Schnabel obtained for the same Sb 72·02, S 27·85, Fe 0·13 (Ramm. Min. Ch., 39).

Pyr., etc.—In the open tube sulphurous and antimonous fumes, the latter condensing as a white sublimate which B.B. is non-volatile. On charcoal fuses, spreads out, gives sulphurous and antimonous fumes, coats the coal white with oxyd of antimony; this coating treated in R.F. tinges the flame greenish-blue. Fus.=1. When pure perfectly soluble in muriatic acid.

Obs.—Occurs with spathic iron in beds, but generally in veins. Often associated with blende, heavy spar, and quartz.

Met with in veins at Wolfsberg, in the Harz: at Bräunsdorf, near Freiberg; at Przibram; Felsobanya, Schemnitz, and Kremnitz, in Hungary, where it often occurs in diverging prisms, several inches long, accompanied by crystals of heavy spar and other mineral species; at Pereta, in Tuscany, in crystals: in Katharinenberg, in the Urals; in Dumfriesshire, fibrous and laminated; in Cornwall, abundant near Padstow and Tintagel; also crystallised at Wheal Boys; at Hare Hill, in Scotland; in Perthshire. Also found at different Mexican mines. Also abundant in Borneo.

In the United States, it occurs sparingly at Carmel, Penobscot Co., Me.; at Cornish and Lyme, N. H.; at "Soldier's Delight," Md.; abundant in the granitic range, south side of Tulare valley, near pass of San Amedio; in the Humboldt mining region in Nevada, and usually argentiferous; also in the mines of Aurora, Esmeralda Co., Nevada. Also found in New Brunswick, 20 m. from Fredericton, S.W. side of St. John R.

This ore affords nearly all the antimony of commerce. The crude antimony of the shops is obtained by simple fusion, which separates the accompanying rock. From this product most of the pharmaceutical preparations of antimony are made, and the pure metal extracted.

This ore was employed by the ancients for coloring the hair, eyebrows, etc., to increase the apparent size of the eye; whence they called the ore πλατυόφθαλμον, from πλατύς, *broad*, and ὀφθαλμός, eye. According to Dioscorides, it was prepared for this purpose by enclosing it in a lump of dough, and then burning it in the coals till reduced to a cinder. It was then extinguished with milk and wine, and again placed upon coals and blown till ignition: after which the heat was discontinued, lest, as Pliny says, "plumbum fiat," *it become lead.* It hence appears that the metal antimony was occasionally seen by the ancients, though not distinguished from lead.

On cryst. see Krenner, Ber. Ak. Wien, li. 1864, 436.

Alt.—Changes on exposure by partial oxydation to *antimony blende* ($2\ Sb^2S^3+Sb^2O^3$), and by further oxydation to *valentinite* (S^3O^3). *Antimony ochre* ($Sb^2O^3+Sb^2O^5$), and also Sb^2O^5+5H are other results of alteration.

30. BISMUTHINITE. Visimutum Sulphure mineralisatum (fr. Riddarhyttan) *Cronst.*, 193 1758. Wismuthglanz *Germ.*; Bismuth sulfuré *Fr.* Sulphuret of Bismuth. Bismuth Glance Bismuthine *Beud.*, Tr., ii. 418, 1832. Bismutholamprite *Glock.*, Syn., 27, 1847.

Orthorhombic. $I\wedge I=91^\circ\ 30'$. Observed planes I, $i\text{-}\bar{\imath}$, $i\text{-}\breve{\imath}$, $i\text{-}\breve{3}$, Brooke. Cleavage: brachydiagonal perfect; macrodiagonal less so; basal perfect. In acicular crystals. Also massive, with a foliated or fibrous structure.

H.=2. G.=6·4—6·459; 7·2; 7·16, Bolivia, Forbes. Lustre metallic. Streak and color lead-gray, inclining to tin-white, with a yellowish or iridescent tarnish. Opaque.

Comp.—Bi^2S^3=Sulphur 18·75, bismuth 81·25=100; isomorphous with stibnite. **Analyses:** 1, H. Rose (Gilb. Ann., lxxii. 192); 2, Wehrle (Baumg. Ztg., x. 385); 3, Scheerer (Pogg., lxv. 299); 4, Hubert (Haid. Ber., iii. 401); 5, Rammelsberg (5th Suppl., 261); 6, F. A. Genth (Am. J. Sci., II. xxiii. 415); 7, D. Forbes (Phil. Mag., IV. xxix. 4):

	S	Bi

7. Bolivia	19·61	80·93=100·54 Forbes.

Pyr., etc.—In the open tube sulphurous fumes, and a white sublimate which B.B. fuses into drops, brown while hot and opaque yellow on cooling. On charcoal at first gives sulphurous fumes, then fuses with spirting, and coats the coal with yellow oxyd of bismuth. Fus.=1. Dissolves readily in hot nitric acid, and a white precipitate falls on diluting with water.

Obs.—Accompanies molybdenite and apatite in quartz, at Brandy Gill, Carrock Fells, in Cumberland, having a foliated structure; occurs near Redruth; at Botallack near Land's End; at Herland Mine, Gwennap; with childrenite, near Callington; at Lanescott mine, near St. Austell; at Johanngeorgenstadt, Altenberg, Schneeberg, in limestone; with cerium ore at Riddarhyttan, Sweden; at the San Baldomero mine, near Sorata, Bolivia, foliated, massive, and acicular.

Occurs with gold, pyrite, and chalcopyrite in Rowan Co., N. C., at the Barnhardt vein. Reported by Shepard to have been found with chrysoberyl at Haddam, Ct.

G. Rose obtained from artificial crystals, $I\wedge I=90^\circ\ 40'$, $i\text{-}\breve{2}\wedge i\text{-}\breve{2}=53^\circ\ 40'$ and $126^\circ\ 20'$, $I\wedge i\text{-}\bar{\imath}=135^\circ\ 20'$, $i\text{-}4\wedge i\text{-}4=28^\circ\ 23'$, $i\text{-}4\wedge i\text{-}4=152^\circ\ 14'$. G.=7·10—6·89, the variation depending on some bismuth present. Pogg., xci. 402.

31. TETRADYMITE. Ore of Tellurium (fr. Tellemark) *Esmark*, Trans. G. Soc., iii. 413, June 1, 1815. Tellurwismuth (fr. Riddarhyttan) *Berz.*, Ac. H. Stockh., 1823. Telluric Bismuth. Tetradymite (fr. Tellurbismuth *Balch*, Am. J. Sci., II. xxxv. 99, 1863.

Hexagonal. $O\wedge R=118^\circ\ 38'$, $R\wedge R=81^\circ\ 2'$; $a=1{\cdot}5865$. $-2\wedge-2=66^\circ\ 40'$, $O\wedge-2=105^\circ\ 16'$, Haid, from Schubkau crystals. Crystals often tabular. Cleavage: basal, very perfect. Also massive, foliated, or granular.

H.=1·5—2. G.=7·2—7·9, Lustre metallic, splendent. Color pale steel gray. Not very sectile. Laminæ flexible. Soils paper.

Comp., Var.—Consists of bismuth and tellurium, with sometimes sulphur and selenium. If sulphur, when present, replaces part of the tellurium, the analyses for the most part afford the general formula **Bi^2 (Te, S)^3**.

Var. 1.—*Free from sulphur.* Bi^2 Te^3=Tellurium 48·1, bismuth 51·9; analyses 1—7. G=7·868, from Dahlonega, **Jackson**: 7·642, id., Balch.

2. *Sulphurous.* Bi^2 ($\frac{2}{3}$ Te + $\frac{1}{3}$S)^3; analyses 8—11. G.=7·500, crystals from Schubkau, Wehrle; 7·514, id., **Baumgartner**; 7·237, fr. Davidson Co., Genth. The name *Bornine*, after von Born, was given by **Beudant** in 1832, and Wehrle's analysis of the Schubkau ore was the only one cited.

3. *Seleniferous.* The Tellemark ore, according to Berzelius, gives B.B. a strong odor of selenium.

Analyses: 1—3, Genth (Am. J. Sci., II. xix. 16); 4, 5, Genth (ib., xxxi. 368); 6, 7, D. M. Balch (ib., xxxv. 99); 8, Wehrle (Schw. J., lix. 482, 1830); 9, Berzelius (Jahresb., xii. 178, 1831); 10, Hruschauer (J. pr. Ch., xlv. 456); 11, C. T. Jackson (This Min., 712, 1850); 12, Genth (Am. J. Sci., II. xvi. 81):

	Te	S	Se	Bi	Fe

12. Davidson Co., N.C.	33·84	5·27	tr.	61·35	——	=100·46 Genth.

Fisher obtained in an analysis of the Fluvanna mineral, 6·81 p. c. of selenium. But Dr. Genth finds in it no selenium or sulphur. C. T. Jackson obtained (Am. J. Sci., II. xxvii. 366) the composition of joseite for the Dahlonega mineral; but the later results of Genth and Balch have shown this to be incorrect.

Pyr.—In the open tube a white sublimate of tellurous acid, which B.B. fuses to colorless drops. On charcoal fuses, gives white fumes, and entirely volatilizes; tinges the R.F. bluish-green; coats the coal at first white (tellurous acid), and finally orange-yellow (oxyd of bismuth); some varieties give sulphurous and selenous odors; that from Fluvanna Co., Va., gave Fisher a red sublimate of selenium in the open tube.

Obs.—Occurs at Schubkau near Schemnitz; at Retzbanya; at Tellemark in Norway; at Bastnaes mine, near Riddarhyttan, Sweden.

In the United States, in Virginia, at the Whitehall gold mines, Spotsylvania Co., at Monroe mine, Stafford Co., and Tellurium mine, Fluvanna Co., with native gold; in North Carolina, Davidson Co., about 5 m. W. of Washington mine, in foliated scales and lamellar masses along with gold, chalcopyrite, magnetite, epidote, limonite, etc.; it was partly altered to a combination of tellurous acid and oxyd of bismuth, with but little of carbonate of bismuth (Genth, l. c.); in Georgia, Lumpkin Co., 4 m. E. of Dahlonega, and also in Cherokee and Polk counties.

32. JOSÉITE. Tellurure de Bismuth *Damour*, Ann. Ch. Phys., III. xiii. 372, 1845. Bornine Tellure bismuthifère du Brésil, *Duf.* [not Bornine *Beud.*] Joseit *Kenng.*, Min., 121, 1853.

Hexagonal, with perfect basal cleavage, like tetradymite. Soft. G.= 7·924—7·936. Lustre submetallic. Color grayish-black, steel-gray. Fragile.

Comp.—From Damour's analyses, Bi^3 Te^2 (S, Se)^2=Bi^3 ($\frac{1}{2}$ Te + $\frac{1}{2}$(S, Se))^4, or a tellurid of bismuth, in which half of the tellurium is replaced by sulphur and selenium. Analyses by Damour (l. c.):

	Te	S	Se	Bi	
1. San José, Brazil	15·93	3·15	1·48	79·15	=99·71
2. " "	15·68	4·58		78·40	=98·66

Rammelsberg obtained from an allied mineral, from Cumberland, England (Min. Ch., 5): Tellurium 6·73, sulphur 6·43, bismuth 84·33=97·49: corresponding to Bi^4, Te, S^4, making the Te S =1:4.

An ore from Sorata, passing for native bismuth, and mentioned under that species, gave Forbes, as there cited, 5·09 p. c. of tellurium, with As 0·38, and S 0·07; while Genth found in another specimen only 0·042 Te. Forbes's specimen may have the formula Bi^8Te. It is foliated nearly like tetradymite.

Pyr.—B.B. the Brazil ore acts nearly like tetradymite. In an open tube it gives off some sulphur, then white fumes of oxyd of tellurium, and then affords a decided odor of selenium; and in the upper part of the tube a white coating with some brick-red over it, due to the selenium; and a yellowish residue below due to the oxyd of bismuth.

Obs.—Found in granular limestone at San José, near Mariana, province of Minas Geraes, Brazil, and first brought to France by Mr. Claussen.

33. WEHRLITE. Argent molybdique *de Born*, Cat. de Raab., ii. 419, 1790. Wasserblei silber, Molybdän-silber, *Wern.*, Letztes Min. Syst., 18, 48, 1817. Molybdic silver. Wismuth glanz *Klapr.*, Beitr., i. 254, 1795. Tellurwismuth *Berz.*, Ak. H. Stockh., 1823. Wismuthspiegel *Weiss.* Spiegelglanz [=Mirror-glance] *Breith.* Tetradymite pt. *many authors.* Wehrlite *Huot*, Min., i. 188, 1841. Pilsenit *Kenng.*, Min., 121, 1853.

Hexagonal. Like tetradymite in perfect basal cleavage.

H.=1—2. G.=8·44, Wehrle. Lustre very bright. Color light steel-gray. Thin folia a little elastic.

Comp.—$Bi(Te, S)^2$, with Te : S=8 : 1, from an imperfect analysis by Wehrle (Baumg. Ztg., ix. 144):

Deutsch-Pilsen	Te 29·74	S 2·33	Bi 61·15	Ag 2·07	=95·29

Pyr., etc.—Like tetradymite.

Obs.—From Deutsch Pilsen, in Hungary. First reported as an ore of silver and molybdenum. Distinguished from tetradymite by its high specific gravity. Breithaupt obtained G.=8·00 with a specimen not wholly free from the gangue.

34. MOLYBDENITE. Not Molybdæna [=product fr. partial reduct. and oxyd. of Galena] *Dioscor.*, *Plin.*, *Agric.* Blyertz, Molybdena pt. [rest graphite] *Wall.*, 131, 1747, *Linn.*, 1748, 1768. Sulphur ferro et stanno saturatum (fr. Bastnaes, etc.), Wasserbley pt., Molybdena pt., *Cronst.*, 139, 1758. Molybdæna (with discov. of metal) *Hielm*, Ak. H. Stockh., 1782, 1788-1793. Monoclinic? Hexagonal? In short or tabular hexagonal prisms. Twins: consisting of three combined crystals, sometimes indicated by striæ on the base of the hexagonal prisms, at right angles to its sides, having occasionally replaced terminal edges. Cleavage: eminent, parallel to base of hexagonal prisms. Commonly foliated, massive, or in scales; also fine granular.

H.=1—1·5, being easily impressed by the nail. G.=4·44—4·8. Lustre metallic. Color pure lead-gray. Streak similar to color, slightly inclined to green. Opaque. Laminæ very flexible, not elastic. Sectile, and almost malleable. Gray trace on paper.

Comp.—MoS^2=Sulphur 41·0, molybdenum 59·0=100. Analyses: 1, Brandes (Schw. J., xxix. 325); 2, Seybert (Am. J. Sci., iv. 1822, 320); 3, 4, Svanberg & Struve (J. pr. Ch., xliv. 257); 5, Wetherill (Am. J. Sci., II. xv. 443):

		Mo	S
1. Altenberg		59·6	40·4=100 Brandes.
2 Chester, Pa.	G.=4·444	59·42	39·68=99·10 Seybert.
3. Smoaland		58·627	40·573, gangue 0·800 S & S.
4. Bohüslan		57·154	39·710, " 3·136 S & S.
5. Reading, Pa.		55·727	38·198, F̶e 3·495, S̈i 2·283 H. 0·297 Wetherill

Pyr., etc.—In the open tube sulphurous fumes. B.B. in the forceps infusible, imparts a yellowish-green color to the flame; on charcoal the pulverized mineral gives in O.F. a strong odor of sulphur, and coats the coal with crystals of molybdic acid, which appear yellow while hot, and white on cooling; near the assay the coating is copper-red, and if the white coating be touched with an intermittent R.F., it assumes a beautiful azure-blue color. Decomposed by nitric acid, leaving a white or grayish residue (molybdic acid).

Obs.—Molybdenite generally occurs imbedded in, or disseminated through, granite, gneiss, zircon-syenite, granular limestone, and other crystalline rocks. At Numedal in Sweden, Arendal, Selbo, and Tellemarken in Norway, Nertschinsk in Russia, and Auerbach in Saxony, it has been observed in hexagonal prisms. Found also at Altenberg and Ehrenfriedersdorf in Saxony; Schlackenwald and Zinnwald in Bohemia; Rathausberg in Austria; near Miask, Urals; Bastnaes, etc., Sweden; in Finland; Laurvig in Norway; Chessy in France; Peru; Brazil; Calbeck Fell, Carrock Fells, and near the source of the Caldew in Cumberland, associated with tungstate of lime and apatite; several of the Cornish mines; in Scotland at East Tulloch, south of Loch Tay; at Mount Coryby on Loch Creran, etc.

In *Maine*, at Blue Hill Bay and Camdage farm, in large crystallizations; also at Brunswick, Bowdoinham, and Sanford, but less interesting. In *Conn.*, at Haddam and the adjoining towns on the Connecticut river, in gneiss in crystals and large plates; also at Saybrook. In *Vermont*, at Newport, with crystals of white apatite. In *N. Hampshire*, at Westmoreland, four miles south of the north village meeting-house, in a vein of mica slate, abundant: at Llandaff in regular tabular crystals; at Franconia. In *Mass.*, at Shutesbury, east of Locke's pond; at Brimfield, with iolite. In *N. York*, two miles southeast of Warwick, in irregular plates associated with rutile, zircon, and pyrite. In *Penn.*, in Chester, on Chester Creek, near Reading; near Concord, Cabarrus Co., N. C., with pyrite in quartz. In *California*, at Excelsior gold mine, in Excelsior district. In *Canada*, at Balsam Lake, Terrace Cove, Lake Superior; north of Balsam Lake, on a small island in Big Turtle Lake, with scapolite, pyroxone, etc., in a vein of quartz intersecting crystalline limestone; at St. Jerome, C. E.; at Seabeach Bay, near Black River, N. W. of L. Superior (48° 46′ N., 87° 17′ W.).

Distinguished from plumbago by its lustre and streak, and also by its behavior before the blowpipe and with acids.

2. SIMPLE SULPHIDS, TELLURIDS, SELENIDS, ARSENIDS, ANTIMONIDS, BISMUTHIDS, PHOSPHIDS, OF METALS OF THE GOLD, IRON, AND TIN GROUPS.

Three divisions of these *Sulphids*, *Arsenids*, etc., are here recognized: (1) a *basic* division, in which the atomic ratio between the sulphur or arsenic metal and the others is 1 to more than one; (2) a *proto* division, with the ratio 1 : 1; (3) a *deuto* division, with the ratio 1 : 2. In these ratios, and in stating the formulas beyond, the halved atomic weights of arsenic, antimony, and bismuth are in view, as stated on p. 26. In the *third* division, some species are included which appear to be combinations of deuto and proto compounds.

The mineral *chalcopyrite* is sometimes referred to the double-binary sulphids, on the ground of its containing, along with a protosulphid, the sulphid $Fe^2\ S^3$; but as the existence of a sesquisulphid $Fe^2\ S^3$ is not established, while $Fe\ S^2$ is the one of common occurrence, the more probable view of the sulphid is that it consists of two sulphids $Fe\ S$ and $Fe\ S^2$ in combination. This view is sustained by the near isomorphism of pyrite and chalcopyrite. The above remark applies also to *bornite* and *pyrrhotite*, in which $Fe^2\ S^3$ has been supposed to be present. $Fe^2\ S^3$, it should be noted, equals $Fe\ S + Fe\ S^2$. *Linnaeite* and *carrolite* come into the same category.

In an article in the American Journal of Science, vol. xliv. 1867, the author gives reasons for believing that the compounds crystallizing in *hexagonal* forms have the number of atoms of the negative element 3, or a multiple of 3, and in *tetragonal* forms, a multiple of 4; whence it follows, that while ordinary *isometric* blende, or sulphid of zinc, for example, may be Zn S, the *hexagonal* or wurtzite, is probably $\mathrm{Zn^2\,S^2}$. The principle, if real, has a very wide application among chemica and mineral species.

9.	"	[17·81]	82·19	Ramm.

Pyr., etc.—B.B. on charcoal fuses to a globule, coating the coal with white oxyd of antimony, and finally giving a globule of almost pure silver. Soluble in nitric acid, leaving oxyd of antimony.

Obs.—Occurs in veins near Wolfach in Baden, Wittichen in Suabia, and at Andreasberg in the Harz, associated with several ores of silver, native arsenic, and galena, and other species; also at Allemont in Dauphiné, Casalla in Spain, and in Bolivia, S. A.

If less rare, this would be a valuable ore of silver. Named from δυσκρασις, *a bad alloy*.

Arsenic Silver (Arsenikalsilber), from Andreasberg, analyzed by Klaproth (Beitr., i. 183), and

Dumenil (Schweig. J., xxxiv. 357), has been shown by Rammelsberg to be probably a mixture of arsenopyrite, arsenical iron, and dyscrasite (Pogg., lxxvii. 262, and Min. Ch., 28).

35C. Domeyko found a mass of ore from Chañarcillo, Chili, which was mainly impure chloro-bromid of silver externally, to contain within (Tr. do Ensayes, 238, 1858) 55·9 p. c. of chlorid of silver, 15·1 of an antimonid of silver, with 14·5 of carbonates and 14·2 ochreous clay; and this antimonid, he says, consists of Sb 36, Ag 64, and "appears to constitute a distinct species." The formula would be Ag Sb. This species is not mentioned in his Mineralogy of 1860.

Domeyko states (Min. 190, 1860) that at Chañarcillo a finely granular grayish-white silver ore disseminated in grains, taking the lustre of silver when rubbed, afforded him 4 to 6 p. c. of antimony; that of the Descubridora mine 4·1 Ag; that of the Rosario mine 5·8 p. c. He also states that the filamentous silver of Bolivia contains Sb 3·7, As 2·3 p. c.

35D. CHANARCILLITE *Dana*.—He describes further (ib.) a silver-white, shining *arsenio-antimonial* ore from Chañarcillo, disseminated through calcite, which afforded him Sb 19·6—21·4, As 23·8—22·3, Ag 53·6—53·3, Fe 3·0—3·0. Regarding the iron as arsenical iron, he deduces the formula $Ag^2 (As, Sb)^3$.

Rammelsberg points out the isomorphism of dyscrasite and the antimonid of zinc, $Zn^3 Sb$, described by Cooke (Am. J. Sci., II. xviii. 229, xx. 222).

36. CHILENITE. Aleacion de plata con bismuto *Domeyko*, Min., 187, 1845. Plata Bismutal *id.*, ib. 185, 1860. Chilenite *Dana*.

Amorphous; granular.

Soft. Silver-white, but tarnishing easily to yellowish.

Comp.—$Ag^6 Bi$=Bismuth 13·8, silver 86·2. Domeyko obtained (Min., 185, 1860) Bi 10·1, Ag 60·1, Cu 6·8, As 2·8, gangue 19·0, corresponding to Bi 14·4, silver 85·6. Also (Ann. d. M., IV. v. 456) Bi 15·3, Ag 84·7. For the last the material was separated from a mass containing 8 to 10 p. c. of it disseminated in small points.

Obs.—From the mine of San Antonio in Copiapo.

36A. BISMUTH SILVER OF SCHAPBACH, SCHAPBACHITE. (Bismuthisches Silber *Selb*, Crell's Ann., 1793, i. 10, Schapbachite *Kenng.*, Min., 118, 1853). According to F. Saudberger, this bismuth-silver, analyzed by Klaproth, is a mixture of bismuthine in needles, argentite, and galena (Jahresb., 1863, 797, 1864). Klaproth obtained (Beitr., ii. 291) Bi 27, Ag 15, Pb 33, Fe 4·3, Cu 0·9, S 16·3. Sandberger gives an analysis by von Muth, who obtained Bi 8·22, Ag 4·05, Pb 45·30, Fe 0·07, S 9·72, quartz 32·33=99·69; which, after separating the iron as $Fe S^2$, affords for the rest 1 $Bi S^3$, 12 R S. D. Forbes remarks with regard to Klaproth's analysis (Phil. Mag., IV. xxv. 105) that the sulphur is sufficient to make sulphids of the metals, and suggests the same conclusion.

37. DOMEYKITE. Arsenikkupfer (fr. Copiapo) *Zinken*, Pogg., xli. 659, 1837. Arseniure de cuivre *Domeyko*, Ann. d. M., IV. iii. 3, 1843; Cobre Blanco *id.*, Min. 138, 1845. Weisskupfer *Hausm.* Cuivre arsenical *Fr.* Arsenical Copper. Domeykite *Haid.*, Handb., 562, 1845. Condurrite *W. Phillips*, Phil. Mag., ii. 286, 1827.

Reniform and botryoidal; also massive and disseminated.

H.=3—3·5. G.=7—7·50, Portage Lake, Genth. Lustre metallic, but dull on exposure. Color tin-white to steel-gray, with a yellowish to pinchbeck-brown, and, afterward, an iridescent tarnish. Fracture uneven.

Comp.—$\mathrm{Ꞓu}^3\,\mathrm{As}^2$=Arsenic 28·3, copper 71·7=100. Analyses: 1, 2, Domeyko (Ann. d. M., IV. iii. 5); 3, 4, F. Field (J. Ch. Soc., x. 289); 5, D. Forbes (2 J. G. Soc., xvii. 44); 6, 7, F. A. Genth (Am. J. Sci., II. xxxiii. 193); 8, 9, Rammelsberg (Pogg., lxxi. 305); 10, Blythe (J. Ch. Soc., i. 213):

8.	Cornwall, *Condurrite*	18·70	70·51, Fe 0·66 Rammelsberg.
9.	" "	17·84	70·02, gangue 1·07 Rammelsberg.
10.	" "	19·51	60·21, Fe 0·25, S 2·33, Ḣ 2·41, C 1·62, H 0·44, N 0·06, O 13·17=100 Blythe

(A) *Condurrite* is a result of the alteration of other ores. It is black and soft, soiling the fingers. It appears, sometimes, at least, to be a mixture of arsenite of copper with domeykite, and some sulphid of copper. Rammelsberg treated one specimen with muriatic acid, and analyzed the soluble and insoluble portions separately, obtaining

1. Insoluble As 13·89 Cu 12·81 S 2·20 gangue 0·70=29·60
2. Soluble $\overline{\mathrm{A}}$s 3·70 $\dot{\mathrm{C}}$u 62·29 $\dot{\mathrm{H}}$ 5·83=71·82.

The insoluble portion contains, therefore, As 4·16, Cu 13·89, with 10·85 of sulphid of copper, corresponding, the last excluded, to arsenic 23·04, copper 76·96=100.

Von Kobell (J. pr. Ch., xxxix. 204), with the same treatment of another specimen, found the composition of the soluble part, $\overline{\mathrm{A}}$s 8·03, $\dot{\mathrm{C}}$u 79·00, F̶e 3·47, $\dot{\mathrm{H}}$ 9·50=100, and the insoluble consisted of arsenic and some sulphid of copper in grains.

Blythe concludes, as a mean of many analyses, that the arsenid of copper contained in condurrite consists of arsenic 28·85, copper 71·15, which corresponds with the domeykite; and Faraday's analysis (Phil Mag., 1827, 286) leads to the same result, or arsenic 29·88, copper 70·11; but Rammelsberg's analysis gives a larger proportion of copper.

Pyr., etc.—In the open tube fuses and gives a white crystalline sublimate of arsenous acid. B.B. on charcoal arsenical fumes and a malleable metallic globule, which, on treatment with soda, gives a globule of pure copper. Not dissolved in muriatic acid, but soluble in nitric acid.

Obs.—From the Chilian mines of Algodones in Coquimbo, in Illapel, San Antonio in Copiapo, etc.

In N. America, found on the Sheldon location, Portage Lake; and mixed with copper-nickel at Michipicoten Island, in L. Superior.

Condurrite is from the Condurrow mine, near Helstone, and Wheal Druid at Carnbrae, near Redruth, Cornwall.

38. ALGODONITE. *F. Field*, J. Ch. Soc., x. 289, 1857.

In incrustations minutely crystalline. Commonly massive and distinctly granular.

H.=4. G.=7·62, from Chili, Genth. Lustre metallic and bright, but becoming dull on exposure. Color steel-gray to silver-white, the latter on a polished surface. Opaque. Fracture sub-conchoidal, affording a granular surface.

Comp.—Ɵu^6 As^2=Ɵu^3 As=As 16·50, Cu 83·50=100. Analyses: 1, F. Field (l. c.); 2—4, Genth (Am. J. Sci. II. xxxiii. 192):

	As	Cu	Ag	
1. Chili	(⅞) 16·23	83·30	0·31	=99·84 Field.
2. "	(⅜) 16·95	82·42	*tr.*	=99·37 Genth.
3. L. Superior	15·30	84·22	0·32	=99·84 Genth.
4. "	16·72	82·35	0·30 Genth.	

In analysis 3, a little whitneyite was mixed with the ore, and hence the higher percentage of copper (Genth).

Pyr.—The same as with domeykite, but less fusible.

Obs.—In Chili, at the silver mine of Algodones, near Coquimbo, in the Cerro de los Seguas, Department of Rancagua; in the United States, in the Lake Superior region. A transported mass of mixed whitneyite and algodonite, weighing 95—100 lbs., was found on St. Louis R. The color is grayer, and the texture more granular and less malleable, than in whitneyite.

39. WHITNEYITE, *Genth*, Am. J. Sci., II. xxvii. 400, 1859, xxxiii. 191, 1862. Darwinite *D. Forbes*, Phil. Mag., IV. xx. 423, 1860.

Massive. Crystalline; very fine granular.

H.=3·5. G.=8·246—8·471, from Lake Superior, varying probably on account of porosity, Genth; 8·64 from Chili, Forbes. Lustre dull and submetallic on surface of fresh fracture, but strong metallic where scratched or rubbed, but soon tarnishing. Color pale reddish to grayish-white, pale reddish-white on a rubbed surface; becoming yellowish-bronze, brown, and brownish-black on exposure. Sometimes iridescent. Opaque. Malleable

Comp.—$\text{Ȼu}^{9}\,\text{As}^{2}$=Arsenic 11·64, copper 88·36=100. **Analyses**: 1—4, F. A. Genth (l. c.); 5 id. (priv. contrib.); 6, D. Forbes (l. c.):

		As	Cu	Ag & insol.		
1.	Michigan	(⅜) 11·61	88·13	0·40	=100·14	Genth.

6.	Chili	(¼) 11·58	88·14	0·28	=100	Forbes.

Pyr.—Less fusible than algodonite; otherwise as in domeykite.

Obs.—In Houghton Co., Michigan, coated with red copper. A loose mass, weighing about 15 lbs., and consisting partly of algodonite, was found on the Pewabic location, 1 m. from Hancock village, Portage Lake; recently found in place on the Sheldon location, near Houghton, Mich.; stated to occur at the Albion location, about a mile from the Cliff mine, in a vein 4 inches wide; also at the Minnesota mine; also in Sonora (Genth), near La Lagoona, a ranch on the road to Libertad, Gulf of California, 35 m. fr. Saric.

Named after J. D. Whitney.

II. GALENA DIVISION.

[For list of species see page 34.]

40. ARGENTITE. Argentum rude plumbei coloris et Galenæ simile, cultro diffinditur, dentibus compressum dilatatur, *Agric.*, 438, 1529; *Germ.* Glaserz, *Agric.*, Interpr., 463, 1546; *Henckel*, Min., 1734 (proving it a sulphur compound). Silfverglas, Minera argenti vitrea, Argentum sulphure mineralisatum, *Wall.*, 308, 1746; *Sage*, Ann. Ch., ii. 250, 1776 (with earliest anal.) Argentit *Haid.*, Handb., 565, 1845. Argyrit *Glock.*, Syn., 23, 1847.

Isometric. Observed planes O, I, 1, 2, 2-2. Figs. 1 to 11, 23. Cleavage: dodecahedral in traces. Also reticulated, arborescent, and filiform; also amorphous.

H.=2—2·5. G.=7·196—7·365. Lustre metallic. Streak and color blackish lead-gray; streak shining. Opaque. Fracture small sub-conchoidal, uneven. Perfectly sectile.

Comp.—Ag S=Sulphur 12·9, silver 87·1=100, **Analyses**: 1, 2, Klaproth (Beitr., i. 158); 3 Lindaker (Vogl's Min. Joach., 78):

		S	Ag	
1.	Joachimsthal	[15]	85	=100 Klaproth.
2.	Himmelsfürst	[14·7]	85·3	=100 Klaproth.
3.	Joachimsthal	14·46	77·58	Pb 3·68, Cu 1·53, Fe 2·02=99·27 Lind.

Pyr., etc.—In the open tube gives off sulphurous acid. B.B. on charcoal fuses with intumescence in O.F., emitting sulphurous fumes, and yielding a globule of silver.

Obs.—This important ore of silver is found at Freiberg, Annaberg, Joachimsthal of the Erzgebirge; at Schemnitz and Kremnitz in Hungary; in Norway near Kongsberg; in the Altai at the Smeinogorsk mine; in the Urals at the Blagodat mine; in Cornwall; in Bolivia; Peru, Chili Mexico at Guanajuato, Zacatecas, Catorce, San Pedro del Potosi, etc.

Occurs in Nevada, at the Comstock lode, at different mines, along with stephanite, native gold etc.; in the vein at Gold Hill; common in the ores of Reese River; probably the chief ore of silver in the Cortez district; in the Kearsarge district, Silver-Sprout vein.

A mass of sulphid of silver is stated by Troost to have been found in Sparta, Tennessee; occurs with native silver and copper in northern Michigan. [A silver ore not yet analyzed, occurs, according to Jackson, with gray antimony, at Cornish, N. H.]

Alt.—Native silver, at Joachimsthal. Also a mixture called silver-black (Silberschwärze *Germ.*).

40A. **Argentopyrite** (Silberkies). This mineral from Joachimsthal, made a species by v. Waltershausen (Ges. Wiss. Göttingen, 1866, No. 2), is shown by Tschermak (Ber. Ak. Wien, liv. 342) to be a pseudomorph consisting of the minerals argentite, marcasite, pyrrhotite, pyrargyrite. It occurs in small hexagonal crystals, which were probably pyrrhotite originally. Von Waltershausen obtained in his analysis, Sulphur 34·2, iron 39·3, silver 26·5.

40B. **Jalpaite** Breithaupt (B. H. Ztg., xv. 85, 1858).—Jalpaite is a cupriferous silver-glance from Jalpa, Mexico. It is isometric in cleavage, and malleable like ordinary argentite; color blackish lead-gray; G.=6·877—6·890. Composition according to R. Richter (l. c.) S 14·36, Ag 71·51, Cu 13·14, Fe 0·79, affording the formula 3 Ag S + Ɵu S or (¾ Ag + ¼ Ɵu) S.

41. NAUMANNITE. Selensilber *G. Rose*, Pogg., xiv. 471, 1828. Selensilberglanz. Séléniure d'argent *Fr.* Seleniuret of Silver. Naumannit *Haid.*, Handb., 565, 1845.

Isometric. In cubes. Cleavage: cubic, perfect. Also massive, granular, and in thin plates.

H.=2·5. G.=8·0. Lustre metallic, splendent. Color and streak iron-black.

Comp.—(Ag, Pb) Se. Pure, Ag Se=Selenium 26·8, silver 73·2. Analyses: 1, Rose (l. c.); 2, Rammelsberg (2d. Suppl., 127, and Min. Ch., 34):

1. Tilkerode	Selenium [29·53]	Silver 65·56	Lead 4·91=100 Rose.
2. "	" 26·52	" 11·67	" 60·15=98·34 Ramm.

In No. 1, Ag : Pb=13 ; 1, in 2, 1 : 5.

Pyr., etc.—B.B. on charcoal it melts easily in the outer flame; in the inner, with some intumescence. With soda and borax it yields a bead of silver.

Obs.—Occurs at Tilkerode in the Harz. Named after the crystallographer Naumann.

According to Del Rio, another selenid of silver occurs at Tasco in Mexico, crystallized in hexagonal tables. (Beud. Tr., ii. 535.)

42. EUCAIRITE. Eukairit *Berz.*, Afh. vi. 42, 1818. Cuivre sélenié argental *H.* Seleniuret of silver and copper. Selenkupfersilber *Germ.*

Massive and granular; also in black metallic films, staining the calcite in which it is contained.

Soft; easily cut by the knife. Lustre metallic. Color between silver-white and lead-gray. Streak shining.

Comp.—Ɵu Se + Ag Se=(Ɵu, Ag) Se=Selenium 31·6, copper 25·3, silver 43·1=100. Analyses: 1–3, Berzelius (l. c.); 4–6, Nordenskiöld (Bull. Soc. Ch., II. vii. 411):

1. Skrikerum	Selenium 28·54	Copper 25·30	Silver 42·73=96·57.
2. "	" 26·00	" 23·05	" 42·73, gangue 8·90=96·88.

6. "	" [32·22]	" 24·86	" 42·57=100 Nord.

Pyr., etc.—B.B. gives copious fumes of selenium, and on charcoal fuses readily to a gray metallic globule, leaving a bead of selenid of silver. With borax a copper reaction. Dissolves in boiling nitric acid.

Obs.—Occurs in small quantities in the Skrikerum copper mine in Smoaland, Sweden, in a kind of serpentine rock, imbedded in calcite; in Chili at Aguas Blancas, near Copiapo (this variety affording Domeyko (Min., 206) Se 32·2, Cu 28·0, Ag. 39·8), and at the mines of Flamenco, a few leagues north of Trespuntas, in the desert of Atacama. Also a similar ore (Ann. d. M., VI. v. 456, and C. R., lviii. 556) on the east side of the Andes of Chili, in the province of San Juan, where it occurs in a narrow vein (10–12 mm. broad), and has a lead-gray color, tarnishes easily and is partly granular, and partly very imperfectly lamellar; at the Cacheuta mine, in the province of Mendoza, with other selenids.

Named by Berzelius from εὖ, *καιρός*, *opportunely*, because found by him soon after the discovery of the metal selenium.

43. CROOKESITE. *A. E. Nordenskiöld*, Œfv. Ak. Stockh., 1866, Bull. Soc. Ch., II. vii. 413

Massive, compact; no trace of crystallization.

H.:=2·5—3. G.=6·90. Lustre metallic. Color lead-gray. Brittle.

Comp.—(Ꞓu, Tl, Ag) Se=Selenium 33·28. copper 45·76, thallium 17·25, silver 3·71=100 **Analyses:** Nordenskiöld (l. c.):

	Se	Cu	Ag	Fe	Tl

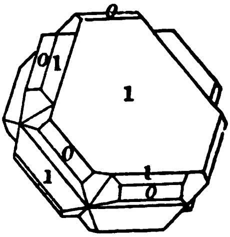
Rossie, N. Y.

72



H.=2·5—2·75. G.=7·25—7·7. Lustre metallic. Color and streak pure lead-gray. Surface of crystals occasionally tarnished. Fracture flat subconchoidal, or even. Frangible.

Comp., Var.—Pb S=Sulphur 13·4, lead 86·6=100. Contains silver, and occasionally selenium (ore fr. Fahlun, Berz.), zinc, cadmium, antimony, copper, as sulphids; besides, also, sometimes native silver and gold; and even platinum has been reported as occurring in a galenite from the Dept. of Charente, France.

Var. 1. *Ordinary.* (*a*) Well crystallized; (*b*) somewhat fibrous and plumose; (*c*) granular coarse or fine; (*d*) crypto-crystalline.

2. *Argentiferous.* All galenite is more or less argentiferous, and no external characters serve to distinguish the kinds that are much so from those that are not.

3. Containing arsenic, or antimony, or an ore of these metals, as impurity. Here belong the *bleischweif*, *targionite*, and *steinmannite*, which appear to be merely impure galenite.

4. Containing an excess of sulphur, through mixture. *Supersulphuretted lead* of Johnston and others (or Johnstonite) is here included. The excess of sulphur is owing to a decomposition of a portion of the mass, setting part of the sulphur free.

Analyses: 1, Thomson (Ed. Phil. J., 1829, 256); 2, 3, Lerch (Ann. Ch. Pharm., xlv. 325):

1. Durham		S 13·02	Pb 85·13	Fe 0·50=98·65	Thomson.	
2. Przibram	G.=7·252	14·41	81·80	Zn 3·59=99·80	L.	Pb S to Zn S as 6 : 1
3. "	G.=7·324	14·18	83·61	2·18=99·97	L.	Pb S to Zn S as 12 : 1

Schwartz found 6·02 p. c. of cadmium in a galena from Altenberg.

The silver present is detected easily by cupellation. The galenite of the Harz affords ·03 to ·05 p. c. of silver; the English ·02 to ·03; that of Leadhills, Scotland, ·03 to ·06; of Monroe, Ct., 3 p. c.; of Roxbury, Ct., assayed by P. Collier, 1·85 p. c. silver; Eaton, N. H., 0·1, C. T. Jackson; Shelburne, N. H., 0·15; of Missouri, ·0012 to ·0027, Litton; Arkansas, 0·03 to ·05, Silliman, Jr.; Middletown, Ct., 0·15 to 0·20 p. c.; Pike's Peak, Colorado, 0·05 to 0·06 p. c.

The following, from Tuscany, contain antimony and silver (E. Bechi, Am. J. Sci., II. xiv. 60):

	S	Pb	Sb	Fe	Cu	Zn	Ag
1. Bottino	12·840	80·700	3·307	1·377	0·440	0·024	0·325= 99·013
2. "	15·245	78·238	4·431	1·828	*tr.*	——	0·485=100·227

4. Argentiera	16·780	72·440	4·308	1·855	4·251	——	0·650=100·284
5. "	15·62	72·90	5·77	1·77	1·11	1·33	0·72 = 99·220

No 5 is the *targionite* of Bechi, occurring in octahedrons with G.=6·932.

The *bleischweif* from Clausthal in the Harz, G.=7·53—7·55, analyzed by Rammelsberg (Min Chem., 49) afforded, Pb S 95·85, Zn S 3·34, Fe S^2 0·54, Sb S^3 0·30=100·03. Schwarz (Ber. Ak. Wien, xxv. 561) found in one specimen of *steinmannite*, Pb S 76·48, with As^2 S^3 9·25, Sb^2 S^3 0·77, Zn S 11·38, Fe S 2·10=99·88; and in another, less lead, only a trace of zinc, very little arsenic, and much antimony; and he concluded that the sulphid of lead was the only constant constituent.

The *supersulphuretted lead* gave Johnston, Pb S 90·38, S 8·71. R. Hofmann found 8·7 p. c. of sulphur in a galenite from New-Sinka, Transylvania, along with 51·30 of sulphate of lead.

Pyr.—In the open tube gives sulphurous fumes. B.B. on charcoal fuses, emits sulphurous fumes, coats the coal yellow, and yields a globule of metallic lead. Soluble in nitric acid.

Obs.—Occurs in beds and veins, both in crystalline and uncrystalline rocks. It is often associated with pyrite, marcasite, blende, chalcopyrite, arsenopyrite, etc., in a gangue of quartz, calcite, barite or fluor, etc.; also with cerussite, anglesite, and other salts of lead, which are frequent results of its alteration. It is also common with gold, and in veins of silver ores. E. J. Chapman remarks that galenite is seldom much argentiferous except when it is associated with mispickel or some other arsenical ore.

At Freiberg in Saxony it occupies veins in gneiss; in Spain, in granite at Linares, and also in Catalonia, Grenada, and elsewhere: at Clausthal and Neudorf in the Harz, and at Przibram in Bohemia, it forms veins in clay slate; in Styria it occurs in the same kind of rock in beds; at Sala in Sweden it forms veins in granular limestone; through the graywacke of Leadhills and the killas of Cornwall, in veins; in mountain limestone in Derbyshire, Cumberland, and the northern districts of England, and also in Bleiberg, and the neighboring localities of Carinthia. In the English mines it is associated with calcite, pearl spar, fluor, barite, witherite, calamine, and blende. Other localities are Joachimsthal, where it is worked principally for the silver; Przibram in Bohemia; in Nertschinsk, East Siberia; in Algeria; near Cape of Good Hope; in Australia; Chili; Bolivia, etc.

Extensive deposits of this ore in the United States exist in Missouri, Illinois, Iowa, and Wisconsin. The ore occurs in stratified limestone, of different periods of the Lower Silurian era, especially the Trenton, associated with blende, smithsonite ("dry-bone" of the miners), calcite, pyrite, and often an ore of copper and cobalt. The mines of Missouri were discovered in 1720, by Francis Renault and Mr. la Motte; they are situated in the counties of Washington, Jefferson, and Madison. Of the Upper Mississippi lead region, five-sixths, says Whitney (Rep. Up. Miss. region, 1862), belong to Wisconsin, and the richest portion is in that part of the State adjoining Illinois and Iowa. The productive lead district is bounded on the west, north, and east by the Mississippi, Wisconsin, and Rock rivers. The occurrence of calc spar in the soil, or sink holes in lines, are considered indications of lead. From a single spot, not exceeding fifty yards square, 1,500 tons of ore have been raised.

Occurs also in *Illinois*, at Cave-in-Rock, associated with fluorite. In *New York*, at Rossie, St

Lawrence Co., in veins from one to three or four feet in width, the crystals often very large (like f. 70, without *i*), with calcite, iron and copper pyrites, and some blende and celestine; near Wurtsboro, Sullivan Co., in a large vein in millstone grit, with blende, iron and copper pyrites, at Ancram, Columbia Co.; in Ulster Co., where often in crystals with the planes *O*, 1, 3-3, *i*-3 or like 70, except that the edges are bevelled. In *Maine*, veins of considerable extent exist at Lubec, where the ore is associated with chalcopyrite and blende; also less extensively at Blue Hill Bay, Bingham, and Parsonsville. In *New Hampshire*, at Eaton, with blende and chalcopyrite; and also at Haverhill, Bath, and Tamworth. In *Vermont*, at Thetford. In *Connecticut*, at Middletown, in a vein in argillite, massive and crystalline. In *Massachusetts*, at Southampton, Leverett, and Sterling. In *Pennsylvania*, at Phenixville and elsewhere. In *Virginia*, at Austin's mines in Wythe Co., Walton's gold mine in Louisa Co., and other places. In *Tennessee*, at Brown's Creek, and at Haysboro, near Nashville, with blende and heavy spar. In *Michigan*, in the region of Chocolate river and elsewhere, and Lake Superior copper districts; on the N. shore of L. Superior, in Neebing on Thunder Bay, and around Black Bay.

In *California*, at many of the gold mines. In *Nevada*, abundant on Walker's river, and at Steamboat Springs, Galena district. In *Arizona*, in the Castle Dome, Eureka, and other districts. In *Colorado*, at Pike's Peak, etc.

Alt.—Minium, anglesite, cerussite, pyromorphite, wulfenite, tetrahedrite, chalcocite, diallogite, quartz, limonite, pyrite, pistomesite (pistopyrite Breith.), calamine, occur as pseudomorphs after galenite, partly from alteration, and partly through removal and substitution. A change to the carbonate (cerussite), with the setting free of sulphur, is the most common.

The specimens regarded as pseudomorphs after pyromorphite, from Bernkastel on the Mosel, Breithaupt makes into a new species (B. H. Ztg., xxi. 99, 1862, xxii. 36, 1863), which he calls *plumbeine*, or one species of his *Sexangulites*, regarding this sulphid of lead as crystallized in hexagonal prisms, and not a pseudomorph. It has G.=6·729—6·87, and *hexagonal* cleavage. He places with it the stalactitic galena of Cornwall, Freiberg, and Przibram.

A galenite occurs in Lebanon Co., Pa., which has an easy *octahedral cleavage*, as first observed by Dr. John Torrey. It is regarded by some as proof of dimorphism of the sulphid of lead, and by others as a result of pseudomorphism after a mineral with octahedral cleavage. See Am. J. Sci., II. xxxv. 126. Dr. Torrey observes that on moderate heating *the cleavage becomes cubic*. In specific gravity it does not differ from ordinary galenite.

Fournetite of Ch. Mène (C. R., li. 463), supposed to be near tetrahedrite, is pronounced by Fournet (C. R., liv. 1096) a mixture of galenite with copper ore.

Artif.—Galenite is sometimes a furnace product. It has been made in crystals by heating oxyd or silicate of lead with vapor of sulphur (Wurtz); also by suspending sulphate of lead in a bag in water saturated with carbonic acid, and in which putrid fermentation is kept up (as by an oyster in the water), there resulting an incrustation of galenite upon the shells (Gages, Brit. Assoc., 206. 1863).

44A. HUASCOLITE *Dana*. (Galena blendosa *Domeyko*, Min., 168, 1860. Sulphid of lead and zinc *D. Forbes*, Phil. Mag., IV. xxv. 110.) The characters are mostly those of galenite. It has a granular or saccharoidal texture, a lead-gray color rather paler than ordinary galenite, but little lustre, and is apparently homogeneous and without any mixture of blende. Domeyko obtained (l. c.) S 19·2, Pb 48·6, Zn 25·6, gangue 3·1; which corresponds nearly to Pb S + 1½ Zn S. It comes from Iugahuas, in the province of Huasco, where it forms large aggregated masses or nodules in the lower part of the vein.

44B. CUPROPLUMBITE Breith. (*Kupferbleispath* of the Germans, *Galena cobriza* Domeyko), from Chili, where it is not rare, appears to be, as Domeyko's name for it and his description implies (Min., 1860, 168), a mere mixture of galenite and chalcocite. The structure, color, and lustre vary from those of galenite to those nearly of chalcocite and covellite: the color a little darker, and passing to iron-gray and indigo-blue; the lustre generally feeble and sometimes almost wanting, and looking, says Domeyko, "as if sulphuret of copper were distributed through it." The specimens contain disseminated ores of copper, and come from a mine in Catemo (Aconcagua). Analyses: 1, Plattner (Pogg., lxi. 671); 2, Field (Am. J. Sci., II. xxvii. 387):

1.	S [15·1]	Pb 64·9	Cu 19·5	Ag 0·5	=100 Plattner.	G.=6·4–6·43
2. Algodoncs	17·00	28·25	53·63		=98·88 Field.	G.=6·10.

Field has named the variety analyzed by him *Alisonite*; it was from Mina Grande, near Coquimbo. According to G. Ulrich, a similar mineral occurs at M'Ivor in Victoria, Australia. Genth suggests that this mineral may have resulted from the alteration of galenite, which is probably true in some cases.

45. CLAUSTHALITE. Selenblei *Zinken*, 1823, Pogg., ii. 415, 1824, iii. 271; H. Rose, ib., ii 415, iii. 281. Seleniuret of Lead. Plomb séleniuré *Fr.* Clausthalie *Beud.*, Tr., ii. 531. Clausthalite.

Kobalt-Bleiglanz [=Cobaltic Galena] *Hausm.*, Nordd. Beitr. B. H., iii. 120. **Kobaltbleierz** *Hausm.*, Handb., 183, 1813; id. *Strom. & Hausm.*, Gött. gel. Anz., 1825, 329. **Selenkobaltblei** *H. Rose*, Pogg., iii. 288, 290. **Tilkerodite** *Haid.*, Handb., 566, 1845.

Isometric. Occurs commonly in fine granular masses; some specimens foliated. Cleavage cubic.

H.=2·5—3. G.=7·6—8·8. Lustre metallic. Color lead-gray, somewhat bluish. Streak darker. Opaque. Fracture granular and shining.

Comp., Var.—Pb Se=Selenium 27·6, lead 72·4=100. Besides (1) the pure selenid of lead, there are others, often arranged as distinct species, which contain cobalt, copper, or mercury, in place of part of the lead, and sometimes a little silver or iron. The proportions of these ingredients vary so much and so irregularly, that the true chemical constitution of the ores, as Rammelsberg states, is yet doubtful. (2) The cobaltic ore (anal. 3), *Tilkerodite* Haid., is here retained as a variety of clausthalite. It affords the formula 6 Pb Se + $Co\ S^3$, according to Rose, who makes the loss mainly selenium; but taking the results as they stand, 6 Pb Se + Co Se.

Analyses: 1, H. Rose (l. c.); 2, Stromeyer (Pogg., ii. 403); 3, H. Rose (Pogg., iii. 288):

	Se	Pb	Co	Fe		
1. *Clausthalite*	27·59	71·81	——	——	=99·40 Rose.	
2. "	28·11	70·98	0·83	——	=99·92 Strom.	G.=7·697
3. *Tilkerodite*	31·42	63·92	3·14	0·45	=98·93 Rose.	

Pyr.—Decrepitates in the closed tube. In the open tube gives selenous fumes and a red sublimate. B.B. on charcoal a strong selenous odor; partially fuses. Coats the coal near the assay at first gray, with a reddish border (selenium), and later yellow (oxyd of lead); when pure entirely volatile; with soda gives a globule of metallic lead. The *tilkerodite* yields a black residue, and gives a cobalt-blue bead with borax.

Obs.—Much resembles a granular galenite; but the faint tinge of blue and the B.B. selenium fumes serve to distinguish it.

Found with the following selenic ores: first by Zinken, near Harzgerode in the Harz with hematite, at Clausthal, Tilkerode, Zorge, and Lehrbach; at Reinsberg, near Freiberg, in Saxony; at the Rio Tinto mines near Seville, Spain; Cacheuta mine, Mendoza, S. A.

46. ZORGITE. Selenblei mit Selenkupfer *H. Rose*, Pogg., ii. 415, 1824. Selenkupferblei, Selenbleikupfer, *Rose*, ib., iii. 293, 294, 296. Seleniuret of Lead and Copper. Zorgite *B. & M.*, 153, 1852. Raphanosmit *v. Kob.*, Taf., 6, 1853.

Massive, granular, like Clausthalite.

H.=2·5. G.=7—7·5. Lustre metallic. Color dark or light lead-gray, sometimes inclining to reddish, and often with a brass-yellow or blue tarnish. Streak darker. Brittle.

Comp.—Pb Se + Cu and Se in varying amounts; and perhaps only a mixture of clausthalite with the other ingredients. Analyses: 1, 2, H. Rose (Pogg., iii. 288); 3, 4, Kersten (ib., xlvi. [illegible]):

	Se	Pb	Cu	Ag	
1. Tilkerode	34·26	47·43	15·15	1·29	F̶e Pb 2·08=100·51 Rose.
2. "	29·96	59.67	7·86	——	Fe Pb 0·44 *undec.* 1·00=99·26 Rose.
3. Glasbach	30·00	53.74	8·02	0·05	F̶e 2·00 S *tr.*, quartz 4·5=98·31 Kerst.
4. "	29·35	63·82	4·00	0·07	Fe S *tr.*, quartz 2·06=99·30 Kerst.

(1) No. 1 is Rose's *Selenbleikupfer*=4 Pb + 4 Cu + 7 Se, or wanting ¼ Se of Pb Se + Cu Se; and (2) No. 2 his *Selenkupferblei*=9 Pb + 4 Cu + 12 Se, which is near 2 Pb Se + Cu Se, the formula of No. 3; (3) No. 4=5 Pb Se + Cu Se. The deficiency of Se in Nos. 1 and 2 may be a result of partial alteration.

Pyr.—Like clausthalite, but yielding a black residue and a globule of copper, with usually, when cupelled, a trace of silver.

Obs.—Occurs under similar circumstances with clausthalite at Tilkerode and Zorge in the Harz; at Glasbach near Gabel in Thuringia, in argillaceous schist with galenite, chalcopyrite, malachite, in a gangue of calcite, siderite, fluorite, and quartz.

47. LEHRBACHITE. Selenblei mit Selenquecksilber *H. Rose*, ii. 418, 1824, iii. 291. Selen-Quecksilberblei *Leonh.*, Handb., 592, 1826. Seleniuret of Lead and Mercury. Lehrbachite *B. & M.*, Min., 153, 1852.

Massive, granular.
G.=7·804—7·876. Color lead-gray, steel-gray, iron-black. Brittle.

Comp.—Pb Se with Hg Se. **Analyses:** 1, Rose (l. c.); 2, 3, Schultz (Ramm. Min. Ch., 1011):

1. Tilkerode Se 24·97 Pb 55·84 Hg 16·94=97·75.
2. " 27·68 61·70 8·33, S 0·8, Fe 0·64=99·15 S., G.=7·089.
3. " 24·41 16·93 55·52, S 1·1=97·96 S., G.=8·104.

Pyr.—In the closed tube gives a lustrous metallic gray sublimate of selenid of mercury; with soda, a sublimate consisting of globules of mercury. In the open tube gives reactions for selenium, and a sublimate of selenate of mercury condensing in drops. On charcoal like clausthalite.

Obs.—From Tilkerode and Lehrbach, in the Harz, like clausthalite.

48. ALTAITE. Tellurblei *G. Rose*, Pogg., xviii. 68, 1830. Tellurid of Lead. Elasmose *Huot*, Min., i. 1841; *O. d'Halloy*, Introd. à la Geol., 1833 (not of Beud. Tr., 1832), etc. Altait *Haid.*, Handb., 556, 1845.

Isometric. Usually massive; rarely in cubes. Cleavage: cubic.
H.=3—3·5. G.=8·159, G. Rose. Lustre metallic. Color tin-white, resembling that of native antimony, with a yellow tarnish. Sectile.

Comp.—Pb Te=Tellurium 38·3, lead 61·7. Analysis by G. Rose (Pogg., xviii. 68) gave silver 1·28 p. c.; and from an imperfect approximative determination of the lead and tellurium Rose assumed them to have the same relation as in hessite, or Tellurium 38·37, lead 60·35.

Pyr.—In the open tube fuses, gives fumes of tellurous acid, forming a white sublimate, which B.B. fuses into colorless drops. On charcoal in R.F. colors the flame bluish, fuses to a globule, coats the coal near the assay with a lustrous metallic ring of tellurid of lead, outside of which it is brownish-yellow, and in O.F. still more yellow. Entirely volatile, except a trace of silver.

Obs.—From Savodinski near Siranovski, in the Altai, with hessite.

Huot says that Beudant in his lectures changed his first use of the name *Elasmose;* and the later use Huot adopts in his Mineralogy, and Omalius d'Halloy in his Introduction to Geology. The confusion thus occasioned, and the unallowable form of the name, are reasons enough for setting it aside altogether, and adopting *Altaite.*

49. BORNITE. Kupferkies pt., Kupfer-Lazul *Henckel*, Pyrit., 1725. Lefverslag, Brun Kopparmalm, Minera Cupri Hepatica, Cuprum sulfure et ferro mineralisatum, *Wall.*, 283, 1747. Cuivre vitreuse violette *Fr. Tri.* Wall., 1753. Koppar-Lazur, Minera Cupri Lazurea, *Cronst.*, 175, 1758. Buntkupfererz *Wern.* Purple Copper Ore *Kirw.* Variegated Copper Ore. Cuivre pyriteux hepatique, *H.* Phillipsite *Beud.*, ii., Tr., ii. 411, 1832. Pyrites erubescens *Dana*, Min., 408, 1837; Poikilopyrites *Glock.*, Grundr., 328, 1839. Bornit *Haid.*, Handb., 562, 1845. Poikilit *Breith.* Erubescite *Dana*, Min., 510, 1850. Cobre abigarrado, Cobre panaceo, *Domeyko.*

Isometric. Observed planes *O*, *I*, 1, 2-2. Figs. 1, 2, 3, 11, 14. Cleavage: octahedral in traces. Twins: f. 50. Massive, structure granular or compact.
H.=3. G.=4·4—5·5. Lustre metallic. Color between copper-red and pinchbeck-brown; speedily tarnishes. Streak pale grayish-black, slightly shining. Fracture small conchoidal, uneven. Brittle.

Comp., Var.—(Ꞓu, Fe) S, the proportion of Ꞓu to Fe varying; and sometimes (there being an excess of sulphur above the ratio of unity) united to Fe S^2 (pyrite), either as an impurity or a chemical compound; at times also mixed with chalcopyrite. As it is a result of the alteration of other ores, occurring only sparingly at great depths in veins, such compounds, or mixtures, are not improbable.

(1) In anal. 1, 5, 6, $\text{Ꞓu} : \text{Fe} = 4 : 1$ nearly, whence the special formula $(\frac{4}{5}\,\text{Ꞓu} + \frac{1}{5}\,\text{Fe})\,\text{S}$=Sulphur 22·11, copper 70·13, Fe 7·76=100.

(2). In anal. 3, 4, 17, 18, $\text{Ꞓu} : \text{Fe} = 2 : 1$ nearly, and hence $(\frac{2}{3}\,\text{Ꞓu} + \frac{1}{3}\,\text{Fe})\,\text{S}$=Sulphur 23·7, copper 62·5, Fe 13·8=100.

(3). In the other analyses $\text{Fe}\,\text{S}^2$ is apparently present. (*a*). Anal. 2, 16, 19, 20, 21, 22 approximate more or less, in the ratio of sulphur to the metals, to 15 : 13, whence the formula $11\,(\text{Ꞓu}, \text{Fe})\,\text{S} + 2\,\text{Fe}\,\text{S}^2$ ($=4\frac{1}{2}\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3$ Ramm.)=S 26·00, Cu 61·87, Fe 12·13. (*b*). Anal. 7 and 13 correspond to $6\,(\text{Ꞓu}, \text{Fe})\,\text{S} + \text{Fe}\,\text{S}^2$ ($=5\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3$ Ramm.). (*c*). Anal. 8, 9, 10, 12, 15, correspond to $4\,(\text{Ꞓu}, \text{Fe})\,\text{S} + \text{Fe}\,\text{S}^2$ ($=3\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3$)=S 28·04, Cu 55·60, Fe 16·36=100. (*d*). Anal. 24=$10\,(\text{Ꞓu}, \text{Fe})\,\text{S} + \text{Fe}\,\text{S}^2$ ($=9\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3$ Ramm.). Rammelsberg writes for No. 5, $10\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3 = 11\,(\text{Ꞓu}, \text{Fe})\,\text{S} + \text{Fe}\,\text{S}^2$; and for No. 6, $8\,\text{Ꞓu}\,\text{S} + \text{Fe}^2\,\text{S}^3 = 9\,\text{Ꞓu}\,\text{S} + \text{Fe}\,\text{S}^2$.

In anal. 25, the proportion of copper is unusually small; $\text{Ꞓu} : \text{Fe} = 3 : 2$; formula $3\,\text{Ꞓu}\,\text{S} + \text{Fe}\,\text{S} + \text{Fe}\,\text{S}^2$ ($=\frac{3}{4}\,\text{Ꞓu} + \frac{1}{4}\,\text{Fe}$) $\text{S} + \frac{1}{4}\,\text{Fe}\,\text{S}^2$. But Mène observes that the ore is not pure, and that after separating the impurity, or what is so regarded, it corresponds to $\text{Ꞓu}\,\text{S} + \text{Fe}\,\text{S}^2$.

The presence of the ordinary sulphid of iron $\text{Fe}\,\text{S}^2$ appears to be far more probable than that of the uncertain $\text{Fe}^2\,\text{S}^3$, as stated on page 33.

Analyses: 1, 2, Berthier (Ann. d. M., III. iii. 48, vii. 540, 556); 3, Phillips (Ann. Phil., 1822, 297); 4, Brandes (Schw. Pyr., etc.—In the closed tube gives a faint sublimate of sulphur. In the open tube yields sulphurous acid, but gives no sublimate. B.B. on charcoal fuses in R.F. to a brittle magnetic globule. The roasted mineral gives with the fluxes the reactions of iron and copper, and with soda a metallic globule. Soluble in nitric acid with separation of sulphur.

Obs.—Occurs with other copper ores, and is a valuable ore of copper. Crystalline varieties are found in Cornwall, and mostly in the mines of Tincroft and Dolcoath near Redruth, where it is called by the miners "horse-flesh ore." Other foreign localities of massive varieties are at Ross Island in Killarney, in Ireland; at Mount Catini, Tuscany; in cupriferous shale in the Mansfeld district, Germany; and in Norway, Siberia, Silesia, and Hungary.

It is the principal copper ore at some Chilian mines, especially those of Tamaya and Sapos; also common in Peru, Bolivia, and Mexico. At the copper mine in Bristol, Conn., it is abundant, and often in fine crystallizations (f. 1, 3, 4, and 14 with planes *O*). At Cheshire, it is met with in cubes, along with barite, malachite, and chalcocite. Found massive at Mahoopeny, near Wilkesbarre, Penn., and in other parts of the same State, in cupriferous shale, associated in small quantities with vitreous copper; also in granite at Chesterfield, Mass.; also in New Jersey. A common ore in Canada, at the Acton and other mines, along a belt of 15–20 m., between L. Memphremagog and Quebec.

Named after von Born, a distinguished mineralogist of the last century. The name Phillipsite has a prior use for another species.

50. BERZELIANITE. Selenkupfer *Berz.*, Afh., vi. 42, 1818. Selenid of copper; Seleniuret of Copper. Cuivre sélénié *Fr.* Berzeline *Beud.*, Tr., ii. 534, 1832. Berzelianite *Dana*, Min., 509, 1850.

In thin dendritic crusts. Soft. Lustre metallic. Color silver-white. Streak shining.

Comp.—Ɵu Se=Selenium 38·4, copper 61·6=100. Analysis by Berzelius (l. c.):

Selenium 40	Copper 64.

Pyr.—In the open tube gives a red sublimate of selenium, with white crystals of selenous acid. B.B. on charcoal selenous fumes, and with soda yields a globule of copper.

Obs.—Occurs at Skrikerum in Sweden, and also near Lehrbach in the Harz.

Beudant gave the name *Berzeline* to this species, which, as it has another earlier application in the science, is given to another form above.

51. CASTILLITE. Castillit *Ramm.*, ZS. G., xviii. 213.

Massive. Distinctly foliated.

H.=3. G.=5·186–5·241. Lustre metallic. Color and tarnish as in bornite.

Comp.—4½ (Ɵu, Zn, Pb, Ag) S+Fe S^3 with Ɵu : Zn : Pb : Ag=30 : 7 : 2½ : 1). Analysis : Rammelsberg (l. c.):

S	Cu	Zn	Pb	Ag	Fe
25·65	41·11	12·09	10·04	4·64	6·49=100·02

Rammelsberg writes the formula $(Cu\ Ag)^2$ S+2 (Cu, Pb, Zn, Fe) S.

Pyr., etc.—B.B. fuses rather difficultly, and changes to a slag colored red by copper. In nitric acid dissolves with the separation of sulphur and sulphate of lead, and gives a blue solution.

Obs.—From Guanasevi in Mexico, where it was considered an argentiferous bornite. It is near bornite in constitution, as observed by Rammelsberg.

52. ALABANDITE. Schwarze Blende (fr. Transylvania) *Müller v. Reichenstein*, Phys. Arb. Fr. in Wien, i. 2nd Quart., 86, 1784; *Bindheim*, Schrift. Ges. Fr., Berl. v. 452, 1784 (making it comp. of Mn, S, Fe, Ag). Schwarzerz *Klapr.*, Beitr., iii. 35, 1802. Braunsteinkies *Leonh.*, Tab., 70, 1806. Brunsteinblende [=Manganblende] *Blumenbach*, Handb., i. 707, 1807. Manganglanz *Karst.*, Tab., 72, 1808. Manganèse sulfuré, *H.*, Tab., iii. 1809. Sulphuret of Manganese. Schwefel-Mangan *Germ.* Alabandine *Beud.*, Tr., ii. 399, 1832. Blumenbachit *Breith.*, B. H. Ztg., xxii. 193, 1866.

Isometric. In cubes and octahedrons. Cleavage: cubic perfect. Twins: simple, with composition-face octahedral; also cruciform, made of five combined octahedrons. Usually granularly massive.

H.=3·5–4. G.=3·95–4·04. 4·036, Mexico. Lustre submetallic. Color iron-black, tarnished brown on exposure. Streak green. Fracture uneven.

Comp.—MnS=Sulphur 36·7, manganese 63·3=100. Analyses: 1, Arfvedson (Ak. H. Stockh. 1822); 2, Bergemann (Jahrb. Min., 1857, 394):

1. Transylvania	Sulphur 37·9	Manganese 62·1=100	Arfvedson.
2. Mexico	" 36·81	" 62·98=99·79	Bergemann.

Earlier analyses by Klaproth, Vauquelin, and Del Rio give erroneous results, the first two finding it mainly Mn, with 11 to 15 S.

Pyr.—Unchanged in the closed tube. In the open tube sulphurous fumes. Roasted on charcoal, the assay is converted into oxyd, which, with the fluxes, gives the reactions of manganese. Soluble in dilute nitric acid, with evolution of sulphuretted hydrogen.

Obs.—Manganblende occurs in veins in the gold mines of Nagyag, Kapnik, and Offenbanya, in Transylvania, associated with tellurium, carbonate of manganese, and quartz; at Gersdorf, near Freiberg, a variety containing a trace of arsenic; in Mexico, at the mine Preciosa in Puebla, with tetrahedrite.

With regard to the cruciform twins of five octahedrons, Schrauf, who describes them, observes that 5 times the tetrahedral angle 70½ is nearly 360°.

53. **SYEPOORITE.** Sulphuret of Cobalt *Middleton*, Phil. Mag., III. xviii. 352, 1846. Syepoorite *J. Nicol*, Min., 458, 1849. Kobaltsulfuret pt., Schwefel Kobalt pt., Kobaltkies pt., Graukobalterz, *Germ.*

Massive, disseminated in grains or veins.
G.=5·45. Color steel-gray, inclining to yellow.

Comp.—Co S=Sulphur 35·2, cobalt 64·8=100. Analysis by Middleton (l. c.):

Sulphur 35·36 Cobalt 64·64=100.

Obs.—From Syepoor, near Rajpootanah in North-west India, where it occurs in ancient schists with pyrrhotite. It is employed by the Indian jewelers to give a rose color to gold.

54. **PENTLANDITE.** Eisen-Nickelkies *Scheerer*, Pogg., lviii. 316, 1843. Sulphuret of Iron and Nickel. Pentlandite *Dufr.*, Min., ii. 549, 1856. Nicopyrite *Shep.*, Min., 307, 1857.

Isometric. Cleavage octahedral. Massive, granular.
H.=3·5—4. G.=4·6. Color light bronze-yellow. Streak light bronze-brown. Not magnetic.

Comp.—$(\frac{1}{3}\mathrm{Ni}+\frac{2}{3}\mathrm{Fe})\,\mathrm{S}$ = Sulphur 36·0, iron 41·9, nickel 22·1=100. Analysis: Scheerer (Pogg., lviii. 315):

	S	Fe	Ni	Cu
1.	36·45	42·70	18·35	1·16=98·66
2.	36·64	40·21	21·07	1·78=99·70

Excluding the copper as chalcopyrite, No. 1 gives S 37·02, Fe 43·73, Ni 19·25; No. 2, S 36·86, Fe 40·86, Ni 22·28. Rivot found (Dufr. Min., l. c.), for the ore from Craigmuir in Argyleshire, S 35·8, Fe 54·8, Ni 7·6, quartz 1·4=99·6.

Pyr.—In the open tube sulphurous fumes. The powdered mineral roasted B.B. on charcoal gives with the fluxes reactions for nickel and iron.

Obs.—Occurs with chalcopyrite in a hornblende rock near Lillehammer in Southern Norway, slightly mixed with magnetite at Craigmuir, 9 m. from Inverary, in Argyleshire, Scotland, in gneiss; also 2 m. from Inverary, both extensively mined; at Wheal Jane in Kenwyn, Cornwall. The ore is valuable for the extraction of nickel.

Named after Mr. Pentland.

55. **GRÜNAUITE** Nickelwismuthglanz *v. Kob.*, J. pr. Ch., vi. 332, 1835. Bismuth Nickel Grünauite *Nicol.*, Min. 458, 1849. Saynit *v. Kob.*, Taf., 13, 1853.

Isometric. Figs. 2, 6, 7. Cleavage octahedral.
H.=4·5. G.=5·13. Lustre metallic. Color light steel-gray to silver-white, often yellowish or grayish through tarnish. Streak dark gray. Brittle.

Comp.—Analyses: 1, Kobell (l. c.). 2, 3, Schnabel (Ramm., 4th Suppl., 164):

	S	Bi	Ni	Fe	Co	Cu	Pb	
1.	38·46	14·11	40·65	3·48	0·28	1·68	1·58	=100·24 **Kobell.**
2.	31·99	10·49	22·03	5·55	11·24	11·59	7·11	=100 Schnabel.
3.	33·10	10·41	22·78	6·06	11·73	11·56	4·36	=100 Schnabel.

The sulphur is to the metals present as 4½ : 3. No probable formula has been deduced.

Pyr., etc.—Fuses to a gray, brittle, magnetic globule, coloring the charcoal greenish-yellow. Dissolves in nitric acid, excepting the sulphur.

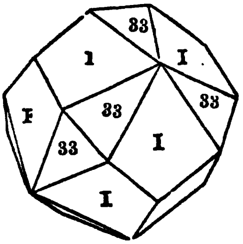
Obs.—Found at Grünau, in Sayn Altenkirchen, with quartz and chalcopyrite.

56. SPHALERITE or BLENDE. Galena inanis, *Germ.* Blende, *Agric.*, Interpr., 465, 1546. Bläude, Pseudo-galena, Zincum S, As, et Fe mineralisatum, *Wall.*, Min., 248, 1747. Zincum cum Fe, S mineralisatum *Bergm.*, Sciagr., 1782. Sulphuret of zinc. Zinc sulfuré *Fr.* Zinc Blende. Sphalerit *Glock.*, Syn., 17, 1847. Black-Jack *Engl. Miners.*

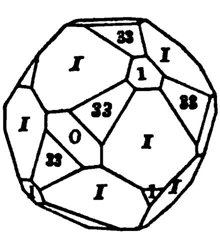
Cleiophane *Nuttal.* Marmatite (fr. Marmato) *Boussingault*, Pogg., xvii. 399, 1829. Przibramite *Huot*, Min., 298, 1841. Marasmolite *Shep.*, Am. J. Sci., II. xii. 210, 1851. Christophit *Breith.*, B. H. Ztg., xxii. 27. Rahtite *Shep.*, Am. J. Sci., II. xli. 209, 1866.

Isometric: tetrahedral, Observed planes, *O*; *I*; 1; 2; i-$\frac{3}{2}$, i-2; 2-2, 3-3, 4-4, 5-5. Figs. 3, 29 to 33; also 73, 74. Cleavage: dodecahedral, highly perfect. Twins: composition-face 1, as in f. 75; also 76, of which 73 is the simple form. Also botryoidal, and other imitative shapes; sometimes fibrous and radiated; also massive, compact.

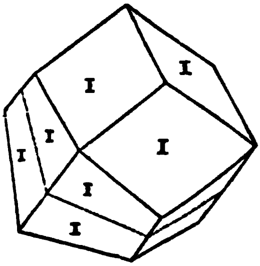
73



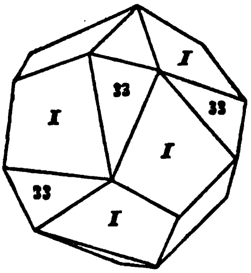
74



75



76



H.=3·5—4. G.=3·9—4·2. 4·063, white, New Jersey. Lustre resinous to adamantine. Color brown, yellow, black, red, green; white or yellow when pure. Streak white—reddish-brown. Transparent—translucent. Fracture conchoidal. Brittle.

Comp., Var.—Zn S=Sulphur 33, zinc 67=100. But often having part of the zinc replaced by iron, and sometimes by cadmium.

Var. 1. *Ordinary.* Containing little or no iron; colors white to yellowish-brown, sometimes black; G.=3·9—4·1. The pure white blende of Franklin, N. J., is the *cleiophane* (anal. 5).

2. *Ferriferous; Marmatite.* Containing 10 p. c. or more of iron; dark-brown to black; G.=3·9—4·2. The proportion of sulphid of iron to sulphid of zinc varies from 1 : 5 to 1 : 2, and the last ratio is that of the *christophite* of Breithaupt (l. c.), a brilliant-black blende from St. Christophe mine, at Breitenbrunn, near Johanngeorgenstadt, having G.=3·91—3·923 (l. c.).

3. *Cadmiferous; Przibramite.* The amount of cadmium present in any blende thus far analysed is less than 5 per cent.

Each of the above varieties may occur (*a*) in crystals; (*b*) firm, fibrous, or columnar, at times radiated or plumose; (*c*) cleavable, massive, or foliated; (*d*) granular, or compact massive.

The *brass-ore* (*Messingerz* Germ.) of early mineralogists is a mixture of blende and chalcopyrite. Shepard's *marasmolite* (l. c.) is a partially decomposed blende containing some free sulphur.

Analyses: 1, Arfvedson (Ac. H. Stockh., 1822, 438, Pogg., i. 62); 2, Löwe (Pogg., xxxviii. 161); 3, Kersten (Pogg., lxiii. 132); 4, C. Kuhlemann (ZS. nat. Ver. Halle, viii. 499); 5, T. H. Henry (Phil. Mag., IV. i. 23); 6, J. L. Smith (Am. J. Sci., II. xx. 250); 7, 8, 9, Jackson (G. Rep. N. Hampshire, 208); 10, Scheerer (Pogg., lxv. 300); 11, 12, Bechi (Am. J. Sci., II. xiv. 61); 13, Scheerer (B. H. Ztg., xix., No. 15); 14, Heinichen (B. H. Ztg., xxii. 27); 15, Lecanu (J. de Pharm., ix. 457); 16, 17, 18, Berthier (Ann. d. M., ix. 419); 19, 20, Boussingault (Pogg., xvii. 399):

20 " "	76·8	23·2=100 Boussingault.

The *marmatite* of anal. 19 affords the formula $3\,ZnS+FeS$=77 Zn S and 23 FeS; of anal. 12, $5\,ZnS+2\,FeS$; another, of brown color, from near Burbach in Siegen, afforded Schnabel (Pogg., cv. 144) $5\,ZnS+FeS$; Breithaupt's *christophite*=$2\,ZnS+FeS$.

Pyr., etc.—In the open tube sulphurous fumes, and generally changes color. B.B. on charcoal, in R.F., some varieties give at first a reddish-brown coating of oxyd of cadmium, and later a coating of oxyd of zinc, which is yellow while hot and white after cooling. With cobalt solution the zinc coating gives a green color when heated in O.F. Most varieties, after roasting, give with borax a reaction for iron. With soda on charcoal in R.F. a strong green zinc flame. Difficultly fusible.

Dissolves in muriatic acid, during which sulphuretted hydrogen is disengaged. Some specimens phosphoresce when struck with a steel or by friction.

Obs.—Occurs in both crystalline and sedimentary rocks, and is usually associated with galena; also with barite, chalcopyrite, fluorite, siderite, and frequently in silver mines.

Derbyshire, Cumberland, and Cornwall, afford different varieties; also Transylvania; Hungary; the Harz; Sahla in Sweden; Ratieborzitz in Bohemia; many Saxon localities. Splendid crystals are found in Binnenthal. A variety having a divergent fibrous structure and presenting botryoidal forms is met with in Cornwall; at Raibel; and at Geroldseck in Baden.

Abounds with the lead ore of Missouri, Wisconsin, Iowa, and Illinois. In *N. York*, Sullivan Co., near Wurtzboro', it constitutes a large part of a lead vein in millstone grit, and is occasionally in octahedrons; in St. Lawrence Co., brown blende occurs at Cooper's falls, in a vein of carbonate of lime; at Mineral Point with galena, and in Fowler, on the farm of Mr. Belmont, in a vein with iron and copper pyrites traversing serpentine; at the Ancram lead mine in Columbia Co., of yellow and brown colors; in limestone at Lockport and other places, in honey and wax-yellow crystals often transparent; with galena on Flat Creek, two miles south-west of Spraker's Basin. In *Mass.*, at Sterling of a cherry-red color, with galena; also yellowish-brown at the Southampton lead mines; at Hatfield, with galena. In *N. Hamp.*, at the Eaton lead mine; at Warren, a large vein of black blende. In *Maine*, at the Lubec lead mines; also at Bingham, Dexter, and Parsonsfield. In *Conn.*, yellowish-green at Brookfield; at Berlin, of a yellow color; brownish-black at Roxbury, and yellowish-brown at Lane's mine, Monroe. In *N. Jersey*, a *white* variety (*cleiophane* of Nuttall) at Franklin. In *Penn.*, at the Wheatley and Perkiomen lead mines, in handsome crystallizations; near Friedensville, Lehigh Co., a *white* waxy var. In *Virginia*, at Walton's gold mine, Louisa Co., and more abundantly at Austin's lead mines, Wythe Co., where it occurs crystallized, or in radiated crystallizations. In *Michigan*, at Prince vein, Lake Superior, abundant In *Illinois*, near Rosiclare, with galenite and calcite; at Marsden's diggings, near Galena, in stalactites, some 6 in. or more through, and covered with cryst. pyrite, and galenite. In *Wisconsin*, at Mineral Point, in fine crystals, and many of large size (3 in. through, or so), altered to smithsonite. In *Tennessee*, at Haysboro', near Nashville.

Named *blende* because, while often resembling galena, it yielded no lead, the word in German meaning *blind* or *deceiving*. *Sphalerite* is from σφαλερός, *treacherous*.

Alt.—Blende by oxydation changes to zinc vitriol. Calamine ($\dot{Z}n^3\ddot{S}i+1\frac{1}{2}\dot{H}$), smithsonite ($\dot{Z}n\ddot{C}$), and limonite occur as pseudomorphs. The sulphate is decomposed by bi-carbonate of lime, producing smithsonite; and the alkaline silicates in solution, acting on the sulphate or carbonate, afford silicate of zinc.

Artif.—Blende may be made in crystals from a solution of sulphate containing some putrifying animal matter; in an experiment by Gages, using oysters for the animal matter, the shells were turned partly into carbonate of zinc and selenite, and some blende incrusted them. Also may be made by subjecting heated oxyd or silicate of zinc to vapors of sulphur.

Rahtite of Shepard (l. c.) is a wholly uncrystalline blende, with G.=4·128, containing iron and copper, and probably a mere mixture of blende and other minerals. Shepard says that it occurs "in the upper decomposed portion of the Ducktown copper lode, associated with melaconite and various mixtures of chalcopyrite, redruthite," etc. The specimen analyzed by Mr. Tyler for Prof. Shepard was iron-black, while Shepard says that the mineral is "dark lead-gray, with a tinge of blue, not unlike some of the ores of antimony." Tyler obtained (l. c.) for the composition of his specimen, S 33·36, Zn 47·86, Fe 6·18, Cu 14·00, giving approximately 10 S, 7 Zn, 1 Fe, 2 Cu, and equivalent to 7 Zn S + Fe S^2 + Ꞓu S, or 7 of blende, with 1 pyrite and 1 chalcocite (redruthite). Since Ꞓu (not Cu) replaces Fe and the related metals in the sulphids, the formula cannot be (Zn, Fe, Cu) S, or that of a cupreous blende.

57. VOLTZITE. Voltzine *Fournet*, Ann. d. M., III. iii. 519, 1833. Oxysulphuret of Zinc. Leber blende *Breith.*, J. pr. Ch., xv. 1838, B. H. Ztg., xxii. 26. Voltzit *Ramm.*, Handw., 260, 1841.

In implanted spherical globules; structure thin curved lamellar.

H.=4—4·5. G.=3·66—3·81. Lustre vitreous to greasy; or pearly on a cleavage surface. Color dirty rose-red, yellowish, brownish. Opaque or subtranslucent.

Var.—G.=3·66 fr. Rosières, Fournet; 3·691 fr. Geyer; 3·711 fr. Marienberg; 3·777 fr. Cornwall; 3·804 fr. Johanngeorgenstadt.

Comp.—4 Zn S + Zn O=Sulphid of zinc 82·73, oxyd of zinc 17·27=100. Analyses: 1, Fournet (l. c.); 2, Lindaker (Vogl's Min. Joach., 175):

1. Rosières	Zn S 82·92	Zn O 15·34	$\dot{F}e$ 1·84	Resinous subst. *tr.*=100·10	Fournet.
2. Joachimsthal	82·75	17·25=100			Lindaker.

Pyr., etc.—B.B. like blende. In muriatic acid affords fumes of sulphuretted hydrogen.

Obs.—Occurs at Rosières, near Pont Gibaud, in Puy de Dôme; Elias mine near Joachimsthal, with galenite, blende, native bismuth, etc.; near Marienberg (the *leberblende*); Hochmuth near Geyer; Cornwall, probably at Redruth; at Bernkastel on the Mosel, in pseudomorphs after quartz.

Named after the French mining engineer, Voltz.

The supposed artificial voltzite from the Freiberg smelting-works has been shown to be blende.

58. HESSITE. Tellursilber *G. Rose*, Pogg., xviii. 64, 1830. Savodinskite *Huot*, Min., i. 187 1841. Telluric Silver. Hessit *Fröbel*, Grundz. Syst. Kryst., 49, 1843.

Orthorhombic, and resembling chalcocite, Kenngott, Peters. Occurring planes *O*, *I*, $i\text{-}\bar{\imath}$, $i\text{-}\breve{\imath}$, $m\text{-}\breve{\imath}$, $i\text{-}\bar{n}$, and others. Cleavage indistinct. Massive; compact or fine-grained; rarely coarse-granular.

H.=2—3·5. G.=8·3—8·6. Lustre metallic. Color between lead-gray and steel-gray. Sectile. Fracture even.

Comp.—Ag Te=Tellurium 37·2, silver 62·8=100. Silver sometimes replaced in part by gold. Analyses: 1, 2, G. Rose (Pogg., xviii. 64); 3, Petz (ib., lvii. 470); 4, Rammelsberg (4th Suppl. 220):

3. Nagyag	G.=8·31–8·45	[37·76]	61·55,	Au 0·69, Fe, Pb, S, *tr.*=100 Petz.
4. Retzbanya		27·96	54·67	Foreign substances 15·25=97·88 Ramm.

Pyr.—In the open tube a faint white sublimate of tellurous acid, which B.B. fuses to colorless globules. On charcoal fuses to a black globule; this treated in R.F. presents on cooling white dendritic points of silver on its surface; with soda gives a globule of silver.

Obs.—Occurs in the Savodinski mine, about 10 versts from the rich silver mine of Zirianovski, in the Altai, in Siberia, in a talcose rock, with pyrite, black blende, and chalcopyrite. Specimens in the museum of Barnaul, on the Ob, are a cubic foot in size. Also found at Nagyag in Transylvania, and at Retzbanya in Hungary; Stanislaus mine, Calaveras Co., Cal.

Kenngott examined crystals from Nagyag, and Peters, from Retzbanya. Hess made the Altai mineral rhombohedral, which Kokscharof does not sustain.

58A. PETZITE. (Tellursilber *Petz*, Pogg., lvii. 470; Tellurgoldsilber *Hausm.*, Handb., 1847. Petzit *Haid.*, Handb., 1845.) Differs from hessite in gold replacing much of the silver. H.=2·5. G.=8·72–8·83, Petz; 9–9·4, Küstel. Color between steel-gray and iron-black, sometimes with pavonine tarnish. Streak iron-black. Brittle. Composition Au Te+4½ Ag Te, Petz; Au Te+3 Ag Te, Genth. Analyses: 1, Petz (l. c.); 2–4, Genth (Am. J. Sci., II. xlv. 310); 5, Küstel (ib., B. H. Ztg., 1866, 128):

1. Nagyag	Te [34·98]	Ag 46·76	Au 18·26, Fe, Pb, S *tr.*=100 Petz.
2. Stanislaus mine	(?) [32·23]	42·14	25·63=100 Genth.
3. Golden Rule mine	32·68	41·86	25·60=100·14 Genth.
4. " "	[34·16]	40·87	24·97=100 Genth.
5. Stanislaus mine	35·40?	40·60	24·80=100·80 Küstel.

Occurs at the localities stated, with other ores of tellurium.

59. DALEMINZITE. Daleminzit *Breith.*, B. H. Ztg., xxi. 98, 1862, xxii. 44, 1863.

Orthorhombic, and isomorphous with chalcocite: $I \wedge I = 116°$. Occurring planes O, I, i-ĭ, 2-2̆, 1-$\frac{1}{2}$.

H.=2–2·5. G.=7·044–7·049. Physical characters like those of argentite.

Comp.—Ag S, or same as for argentite, it being the same chemical compound under an orthorhombic form.

Pyr.—Same as for argentite.

Obs.—From the Himmelfahrt mine near Freiberg. . Much resembles stephanite.

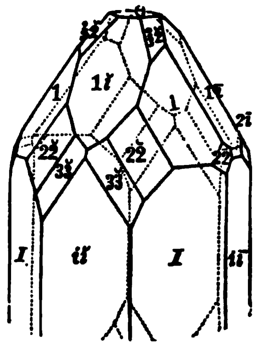
Named from Dalminzien, the ancient name of Freiberg.

Akanthite is also orthorhombic sulphid of silver, but of very different angles.

60. ACANTHITE. Akanthit *Kenng.*, Pogg., xcv. 462, 1855.

Orthorhombic. $I \wedge I = 110° 54'$; $O \wedge 1\text{-}\bar{i} = 124° 42'$; $a : b : c = 1{\cdot}4442 : 1 : 1{\cdot}4523$. Observed planes: as in f. 77, with also vertical i-2̄, i-2̆; domes, $\frac{1}{8}$-ī?, $\frac{2}{3}$-ī?, $\frac{5}{6}$-ī?, $\frac{5}{4}$-ī, 2-ī, 8-ĭ?; octahedral, $\frac{1}{3}$, $\frac{5}{4}$; $\frac{5}{8}$-5̆?; $\frac{1}{2}$-2; $\frac{5}{4}$-$\frac{5}{3}$; $\frac{8}{3}$-8̆; 2-6̆; $\frac{5}{3}$-5̆; $\frac{4}{3}$-4̆; 20-$\frac{5}{3}$?; 4-2̆, $\frac{2}{3}$-2̆, 1-2̆, $\frac{1}{2}$-ĭ, $\frac{15}{8}$-$\frac{15}{4}$? (Dauber). $O \wedge 1\text{-}\breve{i} = 135° 10'$; $O \wedge 1 = 119° 42'$; $O \wedge \frac{2}{3}\text{-}\breve{2} = 140° 40'$, $i\text{-}\breve{i} \wedge 2\text{-}\breve{2} = 138° 33'$, $i\text{-}\breve{i} \wedge I = 124° 33'$, $1 \wedge 1$, over 1-ĭ, $= 88° 3'$ (obs.) $1 \wedge 1\text{-}\bar{i} = 150° 31'$ (obs.) $1 \wedge I = 140° 18'$, $1\text{-}\bar{i} \wedge i\text{-}\bar{i} = 145° 18'$, $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, over i-ī, $= 110° 36'$. Twins: composition parallel to 1-ī. Crystals usually slender-pointed prisms. Cleavage indistinct.

77



Freiberg.

H.=2·5 or under. G.=7·16–7·33; 7·16–7·236, from Freiberg; 7·188–7·326 from Joachimsthal. Lustre metallic. Color iron-black or like argentite. Fracture uneven, giving a shining surface. Sectile.

Comp.—Ag S, or like argentite. P. Weselsky obtained (J. pr. Ch., lxxxi. 487) from a Freiberg specimen 86·71 silver, 12·70 sulphur; from a Joachimsthal specimen, 87·4 silver.

Pyr.—Same as for argentite.

Obs.—At Joachimsthal, with pyrite, argentite, and calcite, usually on quartz; also at the Himmelfürst mine, near Freiberg in Saxony, along with argentite and stephanite. The crystals are parallel with those of stromeyerite when 1-ī is made *I*; in that case *I* ∧ *I*=110° 36′, and *I*-ĭ ∧ 1-ĭ =89° 40′; while in stromeyerite these angles are 119° 35′ and *i*-ĭ ∧ 1-ĭ=91° 44′; and twins are compounded parallel to *I* in each. On cryst., see H. Dauber, Ber. Ak. Wien, xxxix. 685. The prisms 1-ī, and *I*, correspond nearly in angle to the twining form ⅔-ĭ of chalcocite.

The ore analyzed by W. J. Taylor, and referred by him to stromeyerite, may belong to acanthite, as suggested by Kenngott; but this can be made certain only by ascertaining its crystalline form.

Pyr., etc.—Yields nothing volatile in the closed tube. In the open tube gives off sulphurous fumes. B.B. on charcoal melts to a globule, which boils with spirting; with soda is reduced to metallic copper. Soluble in nitric acid.

Obs.—Cornwall affords splendid crystals where it occurs in veins and beds with other ores of copper, and especially near St. Just. It occurs also at Fassnetburn in Haddingtonshire, in Ayrshire, and in Fair Island, Scotland. The compact and massive varieties occur in Siberia, Hesse, Saxony, the Bannat, etc.; Mt. Catini mines in Tuscany; Mexico, Peru, Bolivia, Chili. Near Angina, Tuscany, a crystal has been obtained, weighing half a pound.

In the United States, compact varieties occur in the red sandstone formation at Simsbury and Cheshire, Conn.; also at Schuyler's mines, N. J. Bristol, Conn., affords large and brilliant crystals, f. 79–81; fig. 80, a crystal, with its striæ and irregularities, compounded by two different methods. Another crystal has a small octahedral plane situated obliquely upon the intersection of 1, ½, and adjoining the brachydiagonal section, which is probably the plane ⅔-2. 2-ĭ ∧ 2-ĭ in the Bristol crystals=125° 43′. In Virginia, in the United States copper mine district, Blue Ridge, Orange Co. Between Newmarket and Taneytown, Maryland, east of the Monocacey, with chalcopyrite. In Arizona, near La Paz; in N. W. Sonora. In Nevada, in Washoe, Humboldt, Churchill and Nye Cos.

The *Argent en epis* or *Cuivre spiciforme* of Haüy, which is merely vegetable matter impregnated with this ore, occurs at Frankenberg in Hessia, and also Mahoopeny, Penn.

Under the name *Cupreine*, Breithaupt separates the larger part of the specimens, referred to chalcocite, on the ground alleged that they are *hexagonal* instead of orthorhombic, and have a lower specific gravity. He gives for the angle between the base and a pyramidal face 117° 53′ approximately, and G.=5·5—5·586 of the mineral from 12 different localities. He cites Scheerer's two analyses above of the Tellemark mineral. Other localities mentioned are Kongsberg in Norway, near Freiberg, Sadisdorf, Deutsch-Neudorf, in Saxony; Schmiedeberg in Silesia; Hettstedt and Sangerhausen in Thuringia; near Siegen; Mt. Catini in Tuscany; Bosgolovsk in Siberia; Kargalinsk Steppes in Orenberg; Cornwall; Eleonora and Ulrique in Mexico; West Coast of Africa. Breithaupt is certainly in error with regard to the Cornwall mineral, as the measurements of Phillips and others, and recently of Maskelyne (in a letter to the author), conclusively prove; and probably in error throughout.

Beudant's name, *chalcosine*, has priority. We change the termination *ine*, which ought to be out of the science, and substitute *c* for *s*. *Chalcite* (χαλκιτις in Greek), Aristotle's name for the common ore of Cyprus, cannot be employed in modern mineralogy, because it has the same pronunciation with *calcite*. But with the added syllable, used above, this objection does not hold. Moreover, the word thus altered does not imply an identity of the species with that of Cyprus, about which there is yet much doubt.

Alt.—Occurs altered to chalcopyrite, bornite, covellite, melaconite.

Specimens are often penetrated with the covellite, or indigo-copper, resulting from the alteration. (A) *Digenite* of Breithaupt (l. c.) is probably a mineral of this kind. Plattner obtained B.B., 70·2 of copper and 0·24 of silver, whence the formula $\text{Ꞓu S}+2\ \text{Ꞓu S}^2$, making it a compound of 1 chalcocite + 2 covellite. Localities mentioned are Sangerhausen in Thuringia; Szaska in Transylvania; in the Government of Orenburg; Platten in Bohemia; Angola, W. Coast of Africa; Chili, with cuproplumbite.

(B) *Carmenite* of Hahn (l. c.), from Carmen island, in the Gulf of California, approaches digenite. It is an impure chalcocite, containing visibly, as the author finds after personal examination, much covellite. Hahn analyzed the mass by first separating into two parts, one soluble in muriatic acid, and the other not; and the former was then analyzed, and the composition obtained given as that of carmenite; it was S 26·22, Sb 0·97, Cu 71·30, Fe 1·37, Ag 0·05, gangue 0·77=100·68, corresponding to 1 chalcocite + 1 covellite.

(C) HARRISITE of Shepard (Rep. on Canton Mine, cited in Am. J. Sci., II. xxii. 256 and Pratt, Am. J. Sci. II. xxiii. 409), from Canton mine, Georgia, and later found at the Polk Co. copper mines in East Tennessee, is chalcocite with the cleavage of galena, and, as Genth has proved, is pseudomorphous after galena. Genth's many analyses of the Tennessee mineral (Am. J. Sci. II. xxxiii. 194) show a variation in composition from that of chalcocite to that of a mixture with 2 p. c. of galena. Unaltered galena has been observed within crystals of harrisite both at the Georgia and Tennessee localities. Its color is dark lead-gray and bluish-black. As Genth observes, it is related to the so-called *cuproplumbite* (p. 42).

Artif.—The double sulphate of copper and iron, in carbonated water containing putrescible animal matter, afforded Gages malachite, selenite, and some chalcocite.

62. STROMEYERITE. Silberkupferglanz *Hausm. & Strom.*, Gel. Anz. Gött., ii. 1249, 1816. Argent et cuivre sulfuré *Bournon*, Cat., 212, 1817. Sulphuret of Silver and Copper. Argentiferous Sulphuret of Copper. Cuivre sulfuré argentifère *Fr.* Stromeyerine *Beud.*, Tr., ii. 410, 1832. Stromeyerite *Shep.*, ii. 211, 1835.

Orthorhombic: isomorphous with chalcocite. $I \wedge I = 119° \ 35'$. Observed planes O, $i\text{-}\breve{i}$, $\frac{1}{3}\text{-}\breve{i}$, $\frac{1}{4}$; $O \wedge \frac{1}{4} = 154° \ 16'$, $O \wedge \frac{1}{3}\text{-}\breve{i} = 155° \ 7'$. Also massive, compact.

H.=2·5—3. G.=6·2—6·3. Lustre metallic. Color dark steel-gray. Streak shining. Fracture subconchoidal.

Comp.—(Ag Ꞓu) S, or Ag S + Ꞓu S=Sulphur 15·8, silver 53·1, copper 31·1=100. **Analyses:** 1, W. J. Taylor (Proc. Ac. Philad., Nov., 1859); 2, Stromeyer (Schw. J., xix. 325); 3, Sander (Pogg., xl. 313); 4—7, Domeyko (Ann. d. M., IV. iii. 9); 8, 9, P. Collier (private contrib.):

	S	Ag	Cu	Fe
1. Copiapo	16·35	69·59	11·12	2·86=99·92 Taylor.
2. Schlangenberg, Siberia	15·782	52·272	30·478	0·333=98·865 Stromeyer.
3. Rudelstadt, Silesia	15·92	52·71	30·95	0·24=99·82 Sander.
4. S. Pedro, Chili	17·83	28·79	53·38	——=100 Domeyko.
5. Catemo, "	19·93	24·04	53·94	2·09=100 Domeyko.
6. " "	20·53	16·58	60 58	2·31=100 Domeyko.
7. " "	21·41	12·08	63·98	2·53=100 Domeyko.
8. Arizona	19·44	14·05	64·02	0·48, Hg 1·30=99·29 Collier.
9. "	19·41	7·42	72·73	0·33=99·89 Collier.

Domeyko's analyses indicate a large proportion of the copper sulphid, No. 4 containing, along with Ag S, as Rammelsberg shows (Min. Chem., 54), 9 Ꞓu S; 5, 6 Ꞓu S; 6, 4 Ꞓu S; 7, 3 Ꞓu S. Taylor's analysis corresponds to (Ag, Ꞓu, Fe) S.

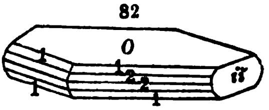
Pyr., etc.—Fuses, but gives no sublimate in the closed tube. In the open tube sulphurous fumes. B.B. on charcoal in O.F. fuses to a semi-malleable globule, which, treated with the fluxes, reacts strongly for copper, and cupelled with lead gives a silver globule. Soluble in nitric acid.

Obs.—Found associated with chalcopyrite at Schlangenberg, near Kolyvan in Siberia; at Rudelstadt, Silesia; also in Chili; at Combavalla in Peru; at Heintzelman mine in Arizona.

Named after Stromeyer, by whom the mineral was first analyzed and established.

63. STERNBERGITE. *Haid.*, Trans. Roy. Soc., Ed., 1827, and Brewst. J., vii 242.

82



Orthorhombic. $I \wedge I = 119° \ 30'$, $O \wedge 1\text{-}\bar{i} = 124° \ 49'$, B. & M.; $a : b : c = 1{\cdot}4379 : 1 : 1{\cdot}7145$. $O \wedge 1 = 121°$, $O \wedge 2 = 106° \ 43'$, $O \wedge 2\text{-}\breve{i} = 120° \ 48'$. Striæ of O macrodiagonal, of sides horizontal. Cleavage: basal highly eminent. Commonly in implanted crystals, forming rose-like or fan-like aggregations. Sometimes compound parallel to I.

H.=1—1·5. G.=4·215. Lustre of O brightly metallic. Color pinchbeck-brown, occasionally a violet-blue tarnish on 1 and 2. Streak black. Opaque. Thin laminæ flexible; may be smoothed down by the nail when bent, like tin foil. Leaves traces on paper like plumbago.

Comp.—Ag S + 3 Fe S + Fe S^2=4 ($\frac{1}{4}$ Ag + $\frac{3}{4}$ Fe) S + Fe S^2=Sulphur 30·4, silver 34·2, iron 35·4 =100. Ratio of sulphur, iron, and silver more exactly 6 : 4 : 1. Analysis by Zippe (Pogg., xxvii. 690):

Sulphur 30·0 Silver 33·2 Iron 36·0=99·2.

Pyr., etc.—In the open tube sulphurous fumes. B.B. on charcoal gives off sulphur and fuses to a magnetic globule, the surface of which shows separated metallic silver. The washed min eral, treated with the fluxes, gives reaction for iron; on charcoal yields a globule of metallic silver Soluble in aqua-regia with separation of sulphur and chlorid of sliver.

Obs.—Occurs with ores of silver, particularly pyrargyrite and stephanite, at Joachimsthal in Bohemia, and Johanngeorgenstadt in Saxony. Named after Count Casper Sternberg of Prague.

The *Flexible silver ore* (*Argent sulfuré flexible* Bourn., *Biegsamer Silberglanz*) from Himmelsfürst mine, near Freiberg, is referred here. According to Brooke & Miller the figure by Phillips is a distorted figure of argentite.

The angles of sternbergite, above given, are from very perfect crystals in Mr. Brooke's collection, which were formerly in the possession of Count Bournon (B. & M., p. 180). The plane 2-ĭ is on the edge of $O \wedge i$-ĭ; and besides this, there is another 10-ĭ, represented by these authors, with also the macrodome 6-ĭ, and the pyramid 2-2.

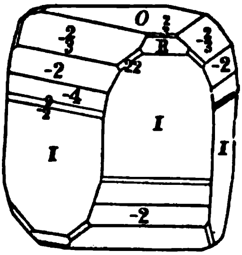
64. CINNABAR. Κιννάβαρις (fr. Spain) *Theophr.* Ἄμμιον *Dioscor.* Minium *Vitruv.*, *Plin.* Minium nativum, *Germ.* Bergzinober, *Agric.*, Interpr., 466, 1546. Cinnabar; Sulphuret of Mercury. Zinnober, Schwefelquecksilber, Merkur-Blende, *Germ.*

Rhombohedral. $R \wedge R = 92° 36'$, $R \wedge O = 127° 6'$; $a = 1{\cdot}1448$. Observed planes: rhombohedrons, $\frac{1}{8}$, $\frac{1}{4}$, $\frac{3}{8}$, $\frac{2}{5}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{4}{5}$, R, $\frac{5}{4}$, $\frac{4}{3}$, $\frac{16}{9}$, 2, $\frac{32}{9}$, 4, $\frac{9}{2}$, $\frac{16}{3}$, 8, $-\frac{8}{5}$, -4, -2, $-\frac{16}{9}$, $-R$, $-\frac{2}{3}$, $-\frac{1}{2}$, $-\frac{2}{5}$, $-\frac{1}{3}$, $-\frac{1}{4}$; pyramids, 22, 62; scalenohedron $\frac{1}{3}^{5}$; and also O, I. Also granular, massive; sometimes forming superficial coatings.

$O \wedge \frac{1}{2} = 146° 32'$
$O \wedge \frac{2}{3} = 138\ 36$
$O \wedge \frac{4}{5} = 133\ 24$
$O \wedge 2 = 110\ 43$
$O \wedge 2 = 71\ 48$

$\frac{4}{5} \wedge \frac{4}{5} = 101° 58'$
$\frac{2}{3} \wedge \frac{2}{3} = 110\ \ 6$
$O \wedge I = 90$
$I \wedge I = 120$

83



Cleavage: I, very perfect. Twins: composition-face O.

H.=2—2.5. G.=8·998, a cleavable variety from Neumarktel. Lustre adamantine, inclining to metallic when dark colored, and to dull in friable varieties. Color cochineal-red, often inclining to brownish-red and lead-gray. Streak scarlet, subtransparent, opaque. Fracture subconchoidal, uneven. Sectile. Polarization circular. Ordinary refraction 2·854 extraordinary 3·201, Descl.

Var.—1. *Ordinary:* either (*a*) *crystallized;* (*b*) *massive,* granular, or compact, bright red to reddish-brown in color; (*c*) *earthy* and bright red.

2. *Hepatic* (Quecksilberlebererz and Quecksilberbranderz, *Germ.*, Inflammable cinnabar), of a liver-brown color, with sometimes a brownish streak, occasionally slaty in structure, though commonly granular or compact. Cinnabar mixed with an organic substance called *idrialine* (q. v.) occurs at Idria.

The *corallinerz* of Idria is a curved lamellar variety of hepatic cinnabar.

Comp.—Hg S (or $Hg^2 S^2$)=Sulphur 13·8, quicksilver 86·2=100. Sometimes impure from clay, oxyd of iron, bitumen. Analyses: 1, 2, Klaproth (Beitr., iv. 14), 3, John (John's Ch. Unt., i. 252); 4, 5, Schnabel (Ramm., 4th Suppl., 269); 6, A. Bealey (J. Ch. Soc., iv.); 7, Klaproth (Beitr., iv. 24):

	S	Hg
1. Neumarktel	14·25	85·00=99·25 Klaproth.
2. Japan	14·75	84·50=99·25 Klaproth.
3. "	17·5	78·4, $\overline{\text{Fe}}$ 1·7, $\ddot{\overline{\text{Al}}}$ 0·7, $\dot{\text{Ca}}$ 1·3, $\ddot{\overline{\text{Mn}}}$ 0·2=100 John.
4. Westphalia	13·67	86·79=100·46 Schnabel.
5. Wetzlar	18·78	84·55, gangue 1·02=99·35 Schnabel.
6. California	11·38	69·36, $\overline{\text{Fe}}$ 1·23, $\dot{\text{Ca}}$ 1·40, $\ddot{\overline{\text{Al}}}$ 0·61, $\dot{\text{Mg}}$ 0·49, $\ddot{\text{Si}}$ 14·30 Bealey.
7. Idria, *hepatic*	13·75	81·80, $\overline{\text{Fe}}$ 0·2, $\ddot{\overline{\text{Al}}}$ 0·55, Cu 0·02, $\ddot{\text{Si}}$ 0·65, $\dot{\text{O}}$ 3·3=99·27 Klaproth.

Pyr.—In the closed tube a black sublimate. Carefully heated in the open tube gives sulphurous fumes and metallic mercury, condensing in minute globules on the cold walls of the tube B.B. on charcoal wholly volatile if pure.

Obs.—Cinnabar occurs in beds in slate rocks and shales, and rarely in granite or porphyry. I has been observed in veins, with ores of iron. The Idria mines are in the Carboniferous formation; those of New Almaden, California, in partially altered Cretaceous or Tertiary beds.

Good crystals occur in the coal formations of Moschellandsberg and Wolfstein in the Palatinate; also in Japan, Mexico, and Brazil. The most important European beds of this ore are at Almaden in Spain, and at Idria in Carniola, where it is usually massive. It occurs at Reichenau in Upper Carinthia; in beds traversing gneiss at Dunbrawa in Transylvania; in graywacke at Windisch Kappel in Carinthia; at Neumarktel in Carniola; at Ripa in Tuscany; at Schemnitz in Hungary in the Urals and Altai; in China abundantly, and in Japan; San Onofre and elsewhere in Mexico; at Huanca Velica in Southern Peru, abundant; in the Provinces of Coquimbo; Copiapo in Chili; forming extensive mines in California, in the coast ranges at different points from Clear lake in the north (near which there is a vein in a bed of sulphur) to San Luis Obispo in the south, the principal mines in which region are at New Almaden and the vicinity, in Santa Clara Co., about 60 m. S.S.E. of San Francisco. Also in Idaho, in limestone, abundant.

This ore is the source of the mercury of commerce, from which it is obtained by sublimation. When pure it is identical with the manufactured *vermilion* of commerce.

The above figure is from an elaborate paper by Schabus, Ber. Ak. Wien, vi. 63.

The name Cinnabar is supposed to come from India, where it is applied to the red resin, dragon's blood. The native cinnabar of Theophrastus is true cinnabar; he speaks of its affording quicksilver. The Latin name of cinnabar, *minium*, is now given to *red lead*, a substance which was early used for adulterating cinnabar, and so got at last the name. It has been said (King on Precious Stones) that the word *mine* (miniera, *Ital.*) and *mineral* come from the Latin for quicksilver mine, *miniaria* (Fodina miniaria).

65. **TIEMANNITE.** Selenquecksilber *Marx*, Schw. J. liv. 223, 1828. Selenid of Mercury Selenmercur, Tiemannit, *Naumann*, Min., 425, 1855.

Massive; compact granular. Cleavage none.

H.=2·5. G. = 7·1—7·37, Clausthal; 7·274, fr. Tilkerode. Lustre metallic. Color steel-gray to blackish lead-gray.

Comp.—Selenid of mercury. Perhaps Hg Se=Selenium 28·4, mercury 71·6=100; but the analyses correspond mostly to Hg^6 Se^5=Selenium 24·8, mercury 75·2=100. Anal. 4 gives Hg^8 Se^{10}. Analyses: 1, 2, Kerl (B. H. Ztg., 1852); 3, Rammelsberg (Pogg., lxxxviii. 39); 4, Schultz (Ramm. Min. Ch., 1010):

	Se	S	Hg
1. Zorge	21·27	0·36	65·52, quartz 10·23=99·57 Kerl.
2. "	24·05	0·12	72·26, " 2·86=99·74 Kerl.
3. "	25·5	——	74·5=100 (quartz excluded) Ramm.
4. Tilkerode	23·61	0·70	74·02=98·33 Schultz.

Pyr.— Decrepitates in the closed tube, and, when pure, entirely sublimes, giving a black sublimate, with the upper edge reddish-brown; with soda a sublimate of metallic mercury. In the open tube emits the odor of selenium, and forms a black to reddish-brown sublimate, with a border of white selenate of mercury, the latter sometimes fusing into drops. On charcoal volatilizes, coloring the outer flame azure-blue, and giving a lustrous metallic coating.

Obs.—Occurs with chalcopyrite near Zorge in the Harz; at Tilkerode; near Clausthal; in California, in the vicinity of Clear lake. Named after the discoverer, Tiemann.

A. ONOFRITE of Haidinger (*Selenschwefelquecksilber* H. Rose, Merkurglanz Breith., Char., 1832), from San Onofre, Mexico, first made known by Del Rio, is either a compound or mixture of selenid and sulphid of mercury. H. Rose obtained (Pogg.. xlvi. 315, 1839) Se 6·49, S 10·30, Hg 81·63=98·12, corresponding to Hg Se+4 Hg S. It is a fine granular ore, of a dark lead gray color, shining when rubbed. G.=5·56, Del Rio; powder soils.

66. **MILLERITE.** Haarkies (as a var. of Schwefelkies) *Wern.*, Bergm. J., 383, 1789; (fr. Johanng.) *Hoffmann*, id., 175, 1791. Fer sulfuré capillaire (as a var. of Pyrite) *H.*, Tr., iv. 1801. Capillary Pyrites. Gediegen Nickel *Klapr.*, Beitr., v. 231, 1810. Schwefelnickel *Berz.*; *Arfvedson*, Ac. H. Stockh., 1822, 427. Nickelkies *Germ.* Sulphuret of Nickel. Nickel sulfuré *Fr.* Harkise *Beud.*, Tr., ii. 400, 1832. Capillose *Chapman*, Min., 185, 1843. Millerit *Haid.*, Handb., 561, 1845. Trichopyrit *Glock.*, Syn., 43, 1847.

Rhombohedral. $R \wedge R=144° \; 8'$, Miller. $a=0·32955$. Observed planes: rhombohedral R, -1, $\frac{1}{2}$, $-\frac{1}{2}$, -3; prismatic I, i-2, i-$\frac{3}{2}$; $R \wedge I=110° \; 50'$, $I \wedge 3=138° \; 47'$, $\frac{1}{2} \wedge \frac{1}{2}=161° \; 22'$. $O \wedge R=159° \; 10'$.

Cleavage: rhombohedral, perfect. Usual in capillary crystals. Rarely in columnar tufted coatings, partly semi-globular and radiated.

H.=3—3·5. G.= 4·6—5·65; 5·65 fr. Saalfeld, Ramm.; 4·601, fr. Joachimsthal, Kenngott. Lustre metallic. Color brass yellow, inclining to bronze-yellow, with often a gray iridescent tarnish. Streak bright. Brittle.

Comp.—Ni S=Sulphur 35·1, nickel 64·9=100. Analyses: 1, Arfvedson (Ac. H. Stockh., 1822, 427); 2, Rammelsberg (1st Suppl., 67); 3, Genth (Am. J. Sci., II. xxxiii. 195):

	S	Ni	Co	Fe	Cu
1.	34·26	64·35	——	——	——=98·61 Arfvedson.
2. Saalfeld	35·79	61·34	——	1·73	1·14=100 Ramm.
3. Gap mine, Pa.	35·14	63·08	0·58	0·40	0·87, gangue 0·28=100·35 G.

A partly altered millerite afforded Genth (l. c.) S 33·60, Ni, Co 59·96, Fe 1·32, Cu 4·63, gangue 0·54=100·05.

Pyr., etc.—In the open tube sulphurous fumes. B.B. on charcoal fuses to a globule. When roasted, gives with borax and salt of phosphorus a violet bead in O.F., becoming gray in R.F. from reduced metallic nickel. On charcoal in R.F. the roasted mineral gives a coherent metallic mass, attractable by the magnet. Most varieties also show traces of copper, cobalt, and iron with the fluxes.

Obs.—Occurs in capillary crystals, in the cavities and among crystals of other minerals. Found at Joachimsthal in Bohemia; Johanngeorgenstadt; Przibram; Riecheldorf; Andreasburg; Himmelfahrt mine near Freiberg; Marienberg in Saxony; Cornwall, and other places. Near Merthyr Tydvil, at Dowlais, it is found in regular crystals, occupying cavities in nodules of spathic iron.

Occurs at the Sterling mine, Antwerp, N. Y., in capillary crystals with spathic iron; the largest crystal yet observed was about a fifth of a line in diameter, and in some cases crystals of spathic iron are transfixed by the needles of millerite (Am. J. Sci. II. ix. 287); in Lancaster Co., Pa., at Gap mine, with pyrrhotite, where it occurs in coatings of a radiated fibrous structure, from a line to a third of an inch thick, often with a velvety surface of crystals, or tufts of radiated needles.

The *capillary pyrites* (*Haarkies*) of Werner was true millerite, from Johanngeorgenstadt, according to Hoffman (Min., iv. 168, 1817). But capillary pyrite and marcasite have sometimes gone by the same name.

67. TROILITE. Pyrrhotite pt. Protosulphid of iron. Sulphid of iron of Meteorites. Troilit *Haid.*, Ber. Ak. Wien, xlvii. 283, 1863.

Resembles pyrrhotite. Observed only massive.

H.=4·0. G.=4·75—4·82; 4·787, fr. Seelasgen, Ramm.; 4·817, fr. Sevier Co., Ramm.; 4·75, fr. Knoxville, Smith. Color tomback-brown. Streak black.

Comp.—Fe S (or $Fe^2 S^2$)=Sulphur 36·36, iron 63·64=100. It thus differs from pyrrhotite in being a true protosulphid. Analyses: 1, J. L. Smith (Am. J. Sci., II. xix. 156); 2, Rammelsberg (Pogg., lxxiv. 62); 3, 4, id. (ib., cxxi. 365):

	S	Fe	Ni	Cu
1. Knoxville, Tenn.	35·67	62·38	0·32	*tr.*, Ši 0·56, Ċu 0·08=98·91 Smith.
2. Seelasgen	37·16	62·84	——	—=100[a] Ramm.

4 " "	36·64	61·80	1·56[b]	—=100 Ramm.

[a] Excluding impurities. [b] With some cobalt.

Pyr., etc.—Same as for pyrrhotite.

Obs.—Almost all iron meteorites contain this sulphid of iron in nodules disseminated more or less sparingly through the mass.

Named after Dominico Troili, who, in 1766, described a meteorite that fell that year at Albareto in Modena, and which contains this species. The meteorite resembles much that of Weston, Conn., in general appearance

68. PYRRHOTITE. Vattenkies, Pyrites fusca, Minera hepatica, pt., *Wall.*, Min., 20J, 212, 1747. Pyrites en prismes hexagonales *Forst.*, Cat., 1772; *Bourn.* de Lisle's Crist., iii. 243, 1783 Magnetischer-Kies *Wern.*, Bergm. J., 383, 1789. Magnetic Pyrites *Kirwan*, 1796. Hexagonal. $O \wedge 1 = 135° 8'$; $a = 0{\cdot}862$. Observed planes: O, I, $\frac{1}{2}$, 1, 1-2, 2-2, i-2.

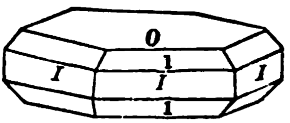
$O \wedge 1 = 90°$. $O \wedge 2\text{-}2 = 119° 53'$. $1 \wedge 1 = 138° 48'$.
$O \wedge 2 = 116\ 28'$. $2 \wedge 2 = 126\ 52'$. $I \wedge I = 120$.

84



Cleavage: O, perfect; I, less so. Commonly massive and amorphous; structure granular. H.=3·5—4·5. G.=4·4—4·68. Lustre metallic. Color between bronze-yellow and copper-red, and subject to speedy tarnish. Streak dark grayish-black. Brittle. Magnetic, being attractable in fine powder by a magnet, even when not affecting an ordinary needle.

Var.—1. *Ordinary.* G. fr. Kongsberg, 4·584 Kenngott; fr. Bodenmais, 4·546 Schaffgotsch; fr. Harzburg, 4·580 Ramm.; fr. Xalastoc, Mexico, 4·564 Ramm.; fr. Trumbull, Ct., 4·640 Ramm.

2. *Niccoliferous.* G. of Klefva, 4·674 Berz; of Hilsen, 4·577 Ramm; of Gap mine 4·543 Ramm.

Comp.—(1) Mostly $Fe^7 S^8 = 6\ Fe\ S + Fe\ S^2$ = Sulphur 39·5, iron 60·5 = 100; but varying to $Fe^8 S^9 = 7\ Fe\ S + Fe\ S^2$, $Fe^9 S^{10} = 8\ Fe\ S + Fe\ S^2$, $Fe^{10} S^{11} = 9\ Fe\ S + Fe\ S^2$. The species is isomorphous with Cd S (greenockite), and Frankenheim wrote the formula Fe S; yet no native pyrrhotite, except that of meteorites (*troilite*), gives this composition. Berzelius found that on heating pyrite it was reduced to $Fe^7 S^8$, and not to Fe S. Rammelsberg obtained in the same way $Fe^7 S^8$, and the other ratios of pyrrhotite.

Analyses: 1, Stromeyer (Gilb. Ann., xviii. 183, 209); 2, 3, Plattner (Pogg., xlvii. 369); 4, 5, Berthier (Ann. d. M., III. xi. 499); 6, H. Rose (Pogg., xlvii.); 7, Schaffgotsch (Pogg., l. 533); 8, Stromeyer (l. c.):

Strecker found nickel in a hexagonal pyrrhotite from Snarum in Norway (B. H. Ztg., xvii. 304).

Pyr., etc.—Unchanged in the closed tube. In the open tube gives sulphurous acid. On charcoal in R.F. fuses to a black magnetic mass; in O.F. is converted into red oxyd, which with fluxes gives only an iron reaction when pure, but many varieties yield small amounts of nickel and cobalt. Decomposed by muriatic acid, with evolution of sulphuretted hydrogen.

Obs.—Occurs at Kongsberg, Modum, Snarum Hilsen, in Norway; Klefva in Sweden; Andreasberg and Treseburg, Harz; Bodenmais in Bavaria; Breitenbrunn, Fahlun, Joachimsthal, N. Tagilsk; Minas Geraes in Brazil, in large tabular crystals; the lavas of Vesuvius; Cornwall; Appin in Argyleshire.

In N. America, in Vermont, at Stafford, Corinth, and Shrewsbury; in many parts of Massachusetts; in Connecticut, in Trumbull with topaz, in Monroe, and elsewhere; in N. York, 1¼ m. N. of Port Henry, Essex Co.; near Natural Bridge in Diana, Lewis Co.; at O'Neil mine and elsewhere in Orange Co. In N. Jersey, Morris Co., at Hurdstown, cleavable massive. In Pennsylvania, at the Gap mine, Lancaster Co., niccoliferous. In Tennessee, at Ducktown mines, abundant. In Canada, in large veins at St. Jerome, etc.

The niccoliferous pyrrhotite is the ore that affords the most of the nickel of commerce. At the Camden nickel works (N. Jersey) this ore (from the Gap mine) is the principal one used, but along with niccoliferous pyrite and some millerite. Prior to 1864, the whole amount of pure nickel made in the country was not over 100,000 lbs. Since then, up to May, 1867, the Camden works have turned out 105,000 lbs.; and now they produce at the rate of 150,000 lbs. a year (letter from J. Wharton, Esq.).

Named from πυῤῥότης, *reddish*.

Alt.—Occurs altered to pyrite (G. Rose, ZS. G., x. 98); also to limonite and siderite.

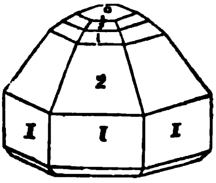
(A) **KRŒBERITE** *D. Forbes* (Phil. Mag., IV. xxix. 9, 1865). Krœberite is a strongly magnetic pyrite, in copper-colored crystals, not yet analyzed, which Forbes says "appears to be principally a subsulphid of iron." The reasons for this opinion are not stated. Named after P. Krœber. It was from between La Paz and Yungas, on the eastern slope of the Andes.

69. GREENOCKITE. Greenockite *Jameson*, Ed. N. Phil. J., xxviii. 390, 1840. Sulphuret of Cadmium *Connel*, ib., 392. Cadmium-blende. Cadmium sulfuré *Fr.*

Hexagonal; hemihedral, with the opposite extremes dissimilar. $O \wedge 1 = 136° 24'$; $a = 0{\cdot}8247$. Observed planes as in the annexed figure, with also 4 and i-2.

$O \wedge \frac{1}{2} = 154° 32'$ $I \wedge 1 = 133° 36'$ $1 \wedge 1$, pyr., $= 139° 39'$
$O \wedge 2 = 117\ 42$ $I \wedge 2 = 152\ 18$ $2 \wedge 2$, " $= 127\ 26$

84A



Cleavage: I, distinct; O, imperfect.

H.=3–3·5. G.=4·8, Brooke; 4·9–4·999, Breithaupt; 4·5, the artificial, Söchting. Lustre adamantine. Color honey-yellow; citron-yellow; orange-yellow—veined parallel with the axis; bronze-yellow. Streak-powder between orange-yellow and brick-red. Nearly transparent. Strong double refraction. Not thermoelectric, Breithaupt.

Comp.—Cd S (or Cd^3S^3)=Sulphur 22·3, cadmium 77·7. Analysis by Connel (loc. cit.): Sulphur 22·56, and cadmium 77·30=99·86.

Pyr., etc.—In the closed tube assumes a carmine-red color while hot, fading to the original yellow on cooling. In the open tube gives sulphurous acid. B.B. on charcoal, either alone or with soda, gives in R.F. a reddish-brown coating. Soluble in muriatic acid, affording sulphuretted hydrogen.

Obs.—Occurs in short hexagonal crystals at Bishoptown, in Renfrewshire, Scotland, in a porphyritic trap and amygdaloid, associated with prehnite; also at Przibram in Bohemia, on blende; at the Ueberoth zinc mine, near Friedensville, Lehigh Co., Pa.

This species is related in form to niccolite and breithauptite. It has been found as a furnace product (Ann. Ch. Pharm., lxxxvii. 34, and Halle Zeitschr., i. 346, 1853).

Named after Lord Greenock (later Earl Cathcart). The first crystal was found near 60 years since by Mr. Brown of Lanfyne, and was taken by him for blende. It was over half an inch across.

70. WURTZITE. *C. Friedel*, C. R., liii. 983, 1861. Spiauterit *Breith.*, B. H. Ztg., xxi. 98, 1862 xxv. 193.

Hexagonal. Isomorphous with greenockite. $O \wedge 1 = 129°$ (approximately) Occurring form a quartzoid, with occasionally planes of the cor responding hexagonal prism; the latter planes horizontally striated Cleavage: basal and prismatic.

H.=3·5–4. G.=3·98. Lustre vitreous. Color brownish-black. Streak brown.

Comp.—Zn S, or perhaps more correctly $Zn^2 S^2$. Analysis by C. Friedel (l. c.):

S	Zn	Fe	Pb	Sb	Cu
32·6	55·6	8·0	2·7	0·2	*tr.*=99·1.

The lead and antimony are from the gangue.

Pyr.—Same as for sphalerite or blende.

Obs.—From a silver-mine near Oruro in Bolivia. According to Breithaupt (l. c.) a radiated blende from Przibram (his *spiauterite*) is hexagonal; also that from Albergaria Velha in Portugal; from Quesbesita, Peru, in tabular crystals grouped and forming a crust, some of the crystals ½ inch across.

Wurtzite and sphalerite are the same compound under distinct crystalline forms—a case of dimorphism.

Named after the French chemist, Adolphe Wurtz.

Artif.—May be made in crystals by a long and high heating of amorphous blende (C. R., lxii. 999); or better by subliming the blende in a current of sulphurous acid, long, transparent, colorless hexagonal prisms having been thus formed (ib., lxiii. 188).

71. NICCOLITE. Kupfernickel [=False Copper, it resembling but not yielding copper] *Hiärne*, Anledn. Malm og Berg., 76, 1694. Cuprum Nicolai [mistaken trl. of Kupf.] *J. Woodward*, Foss., 1728. 8. Sangerhausen	54·89	43·21	0·54	——	——	——	1·35=99·99 Grunow.

An ore from Balen in the Pyrenees afforded Berthier As 33·0, Sb 27·8, Ni 33·0, Fe 1·4, S 2·8, quartz 2·0=100, in which a large part of the arsenic is replaced by antimony.

Pyr., etc.—In the closed tube a faint white crystalline sublimate of arsenous acid. In the open tube arsenous acid, with a trace of sulphurous acid, the assay becoming yellowish-green. On charcoal gives arsenical fumes and fuses to a globule, which, treated with borax glass, affords, by successive oxydation, reactions for iron, cobalt, and nickel. Soluble in nitromuriatic acid.

Obs.—Accompanies cobalt, silver, and copper in the Saxon mines of Annaberg, Schneeberg, etc.; also in Thuringia, Hesse, and Styria, and at Allemont in Dauphiny; occasionally in Cornwall, as at Pengelly and Wheal Chance; formerly at the Hilderstone Hills, Scotland; at Chanarcillo, near Copiapo, and at Huasco, Chili; abundant at Mina de la Rioja, Oriocha, in the Argentine Provinces.

Found at Chatham, Conn., in gneiss, associated with smaltite.

This is an important ore of nickel.

Named from the contained metal. The name of the species should be formed from the Latin word for nickel, *niccolum*, proposed by Cronstedt, and hence should be written *niccoline*, or better *niccolite*, in place of Beudant's *nickeline*. *Nickeline* and *nickeliferous* are not more proper words than would be *copperine* and *copperiferous*.

72. BREITHAUPTITE. Antimonnickel *Stromeyer & Hausm.*, Gel. Anz. Gött., 2001, 1833. Antimonial Nickel; Antimoniet of Nickel. Hartmannite *Chapman*, Min., 1843. Breithauptit *Haid.*, Handb., 559, 1845.

Hexagonal. $O \wedge 1 = 135° 15'$; $a = 0·8585$. Observed planes: O, $\frac{1}{2}$, $\frac{3}{2}$, I. $O \wedge \frac{1}{2} = 153° 38'$, $O \wedge \frac{3}{2} = 123° 55'$. In thin hexagonal plates. Also arborescent and disseminated.

H.=5·5. G.=7·541 Breithaupt. Lustre metallic, splendent. Color in the fresh fracture light copper-red, inclining strongly to violet. Streak reddish-brown. Opaque. Fracture uneven—small subconchoidal. Brittle.

Comp.—Ni Sb (or $Ni^2 Sb^2$)=Antimony 67·4, nickel 32·6=100. Analyses: 1, 2, Stromeyer (Pogg., xxxi. 134):

1.	Sb 63·734	Ni 28·946	Fe 0·866	Galena 6·437=99·983
2.	59·706	27·054	0·842	12·357=99·959

Pyr.—In the open tube white antimonial fumes. On charcoal fuses in R.F., gives off antimonial vapors, and coats the coal white; if lead is present a yellow coating near the assay; treated with soda the odor of arsenic may be distinguished in most specimens.

Obs.—Found in the Harz at Andreasberg, with calcite, galenite, and smaltine. Has been observed as a furnace product, crystallized.

Named after the Saxon mineralogist, Breithaupt.

73. KANEITE. Arseniuret of Manganese *Kane*, Q. J. Sci., II. vi. 382. Kaneit *Haid.*, Handb. 559, 1845.

In botryoidal masses, also amorphous; structure foliated or granular. H. above 5? stated as hard. G.=5·55. Lustre metallic. Color grayish-white, with a black tarnish. Opaque. Fracture uneven. Brittle.

Analysis by Kane (l. c.): Manganese 45·5, arsenic 51·8, and a trace of iron=97·3, corresponding to Mn As=Manganese 42·4, arsenic 57·6=100.

B.B. burns with a blue flame, and falls to powder; at a higher temperature the arsenic evaporates, and covers the charcoal with a white powder. Dissolves in aqua regia, without leaving any residue.

It is supposed to be from Saxony, and was first observed by R. J. Kane, of Dublin, attached to a mass of galenite.

74. SCHREIBERSITE. Schreibersit *Haid.*, Haid. Ber., iii. 69, 1847.

In steel-gray folia and grains. Folia flexible.
H.=6·5 G.=7·01—7·22. Magnetic.

Comp.—Analyses: 1, Patera (Haid. Ber., l. c., and Am. J. Sci., II. viii. 439); 2, Fisher (Am. J Sci., II. xix. 157); 3, 4, 5, J. L. Smith (ib., xix. 157):

5. "	14·86	56·53	28·12	"	0·28, Cu *tr.*, " " " Smith.

Obs.—Found only in meteoric iron.

The *schreibersite* of *Shepard* (Am. J. Sci., II. ii.), from a meteorite, is supposed to be a "sesqui-sulphuret of chromium." The name has been changed to *shepardite* by Haidinger. It is not contained in Shepard's recent list of meteoric minerals, in ibid., xliii. 28.

III. PYRITE DIVISION.

[See for list of species, page 34].

75. PYRITE. Σπῖνος *Theophr.* Πυρίτης pt. *Dioscor.*, E. cxlii. Pyrites pt. *Plin.*, xxxvi., 30 Pyrites pt., *Arab.* Marchasita, *Germ.* Kis, *Agric.*, 334, 431, 467, 1529, 1546. Pyrites pt. Schoharie.

common. Cubic faces often striated, with striations of adjoining faces at right angles, and due to oscillatory combination of the cube and pyritohedron the striæ having the direction of the edges between *O* and *i*-2 in f. 46

Crystals sometimes acicular through elongation of cubic and other forms. Cleavage: cubic and octahedral, more or less distinct. Twins: 1, composition-face *I*; this composition either (*a*) single, or (*b*) repeated parallel to each *I*, producing thus forms like f. 90, consisting of combined pyritohedrons, also a cube, having striations on each face parallel to its sides and meeting at an angle in the diagonals. 2, C.-face *O*, fig. 89. Also reniform, globular, stalactitic, with a crystalline surface; sometimes radiated subfibrous. Also amorphous.

H.=6—6·5. G.=4·83—5·2; 5·185, polished crystals, Zepharovich. Lustre metallic, splendent to glistening. Color a pale brass-yellow, nearly uniform. Streak greenish or brownish-black. Opaque. Fracture conchoidal, uneven. Brittle. Strikes fire with steel.

Comp., Var.—$Fe\ S^2$=Sulphur 53·3, iron 46·7=100. Nickel, cobalt, and thallium, and also copper, sometimes replace a little of the iron, or else occur as mixtures; and gold is sometimes present, distributed invisibly through it. Thallium occurs in traces in much pyrite, it showing its presence often in the chimneys of furnaces where pyrite, or ores containing it, are roasted.

Var. 1. *Ordinary.* (*a*) In distinct crystals; (*b*) nodular, or concretionary, often radiated within; (*c*) stalactitic; (*d*) amorphous.

2. *Niccoliferous.* Schnabel found 0·168 of nickel in a kind from a silver mine near Eckerhagen. A pyrite from the Kearney ore-bed, Gouverneur, N. Y., is similar; it is pale bronze in color, and radiated botryoidal; H.=5·5; G.=4·863 (Am. J. Sci., II. xv. 444).

3. *Cobaltiferous.* Specimens from Cornwall, Lebanon Co., Pa. (f. 88), afforded J. M. Blake 2 p. c. of cobalt. Fig. 88, by Mr. Blake, represents the planes about an angle of the cube, one of which, 2-½, has not been before observed in pyrite, though known in cobaltite (p. 71). The crystals are much distorted.

4. *Cupriferous.* A variety from Cornwall, Lebanon Co., Pa., gave J. C. Booth (Dana's Min., 1854, 55) 2·39 p. c. of copper, affording the formula $(Fe, Cu)\ S^2$. The analysis gave S 53·37, Fe 44·47, Cu 2·39. It tarnishes readily, assuming the bluish tarnish of steel.

5. *Stanniferous; Ballesterosite* Schulz & Paillette (Bull. G. Fr., II. vii., 16). A kind in cubes, containing tin and zinc, occurring in argillite, 6 m. S. of Ribadeo, in Galicia. Named after Lopez Ballesteros.

6. *Auriferous.* Containing native gold. See under GOLD. The pyrite of most gold regions is auriferous. The fact is not apparent in any of the external characters.

7. *Argentiferous.* From Hungary.

8. *Thalliferous.* The pyrite of the Rammelsberg mine, near Goslar, Prussia, is especially rich in thallium; and also that of Saalfeld. Thallium occurs in the furnaces of the Bethlehem (Pa.) iron works, which W. T. Roepper attributes to the pyrite of the Pennsylvania coal used.

Pyr., etc.—In the closed tube a sublimate of sulphur and a magnetic residue. B.B. on charcoal gives off sulphur, burning with a blue flame, leaving a residue which reacts like pyrrhotite. Insoluble in muriatic acid, but decomposed by nitric acid.

Obs.—Pyrite occurs abundantly in rocks of all ages, from the oldest crystalline to the most recent alluvial deposits. It usually occurs in small cubes, but often modified as above described; also in irregular spheroidal nodules and in veins, in clay slate, argillaceous sandstones, the coal formation, etc. Cubes of gigantic dimensions have been found in some of the Cornish mines; pentagonal dodecahedrons and other forms occur on the island of Elba, sometimes five to six inches in diameter. Large octahedral crystals are found at Persberg in Sweden. Magnificent crystals come from Peru; also from Traversella in Piedmont, twins of which locality are figured by Q. Sella, one of them a large pyritohedron (f. 47) with a small converse pyritohedron (f. 48) astride of each of the six cubic edges. Alston-Moor, Derbyshire, Fahlun in Sweden, Kongsberg in Norway, are well-known localities. The clay at Münden in Hanover, and the chalk at Lewes in Surrey, have afforded some remarkable compound crystals. It has also been met with in the Vesuvian lavas in small irregular crystals.

In *Maine*, at Corinna, Peru, Waterville, and Farmington, in crystals; at Bingham (saw mills), Brooksville, and Jewell's Id., massive. In *N. Hampshire*, at Unity, massive. In *Mass.*, at Heath, in cryst.; at Hawley and Hubbardston, massive. In *Vermont*, at Shoreham, in limestone, crystals abundant; Hartford, in cubes 2–4 in. In *Conn.*, at Lane's mine, Monroe, in octahedrons; Orange and Milford, in cubes in chlorite slate; Middletown lead mine, sometimes acicular, and also scattered over quartz, like f. 89; at Stafford, in mica slate; massive at Colchester, Ashford, Tolland, Stafford, and Union. In *N. York*, at Rossie, fine crystals (f. 85, 87) occur at the lead mine in green shale; at Schoharie, a mile west of the court-house, in single and compound crystals, often highly polished and abundant; in interesting crystals at Johnsburgh and Chester, Warren Co.; in gneiss near Yonkers; in Orange Co., at Warwick and Deerpark; in Jefferson Co., in Champion and near Oxbow on the banks of Vrooman's lake, in modified octahedrons (f. 7); massive in Franklin, Putnam, and Orange Cos., etc. In *Pennsylvania*, in crystals at Little Britain, Lancaster Co.; at Chester, Delaware Co.; in Carbon and York Cos.; at Knauertown, Chester Co.; in Cornwall, Lebanon Co., in lustrous cubo-octahedrons, and with an elegant steel tarnish, sometimes an inch through; at Pottstown, near French Creek, in large yellow octahedrons. In *Wisconsin*, near Mineral Point. In *Illinois*, near Galena, at Marsden's Diggings, in stalactites of great beauty with a surface of crystals. In *N. Car.*, near Greensboro', Guilford Co., in crystals. Auriferous pyrite is common at the mines of Colorado, and many of those of California, as well as in Virginia and the States south.

In *Canada*, 2 miles N. W. of Brockville, a cobaltiferous var., in the Laurentian; on the river Assumption, seignory of Daillebout, and at Escott, a niccoliferous var., containing also some cobalt.

This species affords the greater part of the sulphate of iron and sulphuric acid of commerce, and also a considerable portion of the sulphur and alum. The auriferous variety is worked for gold in many gold regions.

The name *pyrite* is derived from πῦρ, *fire*, and alludes to the sparks from friction. Pliny mentions several things as included under the name (xxxvi. 30): (1) a stone used for grindstones; (2) a kind which so readily fires punk or sulphur that he distinguishes it as *pyrites vivus*, and which may have been flint or a related variety of quartz, as has been supposed, but more probably was *emery*, since he describes it as the heaviest of all; (3) a kind resembling brass or copper: (4) a porous stone, perhaps a sandstone or buhrstone. The brassy kind was in all probability our pyrite. But with it were confounded copper pyrites (chalcopyrite), besides marcasite and pyrrhotite, although these three kinds of pyrites fail of the scintillations. In fact, Dioscorides calls pyrite an ore of copper, yet in the next sentence admits that some kinds contain no copper; and moreover, he states that the mineral gives sparks. This confounding of iron and copper pyrites is apparent also in the descriptions of the vitriols (sulphates of iron and copper) by Pliny and other ancient writers, and equally so in the mineralogy of the world for more than fifteen centuries after Pliny, as is even now apparent in the principal languages of Europe. *Kupferwasser* (copper-water) of the Germans being the copperas of the English and couperose of the French. It is quite probable that *copperas* and *couperose* are in fact corruptions of the German word, instead of derivatives from *cuprosa* or *cuprirosa*, as usually stated, for the Latin *u* would not have become *ou* in French.

Under the name *marcasite* or *marchasite*, of Spanish or Arabic origin, the older mineralogists, Henckel, Wallerius, Linnæus, etc., included distinctively crystallized pyrite, the cubic preëminently; the nodular and other varieties being called *pyrites*, and the less yellow or brownish and softer kinds, *wasserkies*, this last including our *marcasite* and *pyrrhotite*, and some *true pyrite*. Werner first made *pyrrhotite* a distinct species.

Alt.—Pyrite readily changes to a sulphate of iron by oxydation, some sulphur being set free. Also to limonite on its surface, and afterward throughout, by the action of a solution of bicarbonate of lime carrying off the sulphuric acid as change proceeds, and from limonite to red oxyd of iron. Green vitriol, limonite, göthite, hematite, quartz, graphite, ochreous clay, occur as pseudomorphs after pyrite.

Artif.—May be made by the slow reduction of sulphate of sesquioxyd of iron in presence of some carbonate.

76. HAUERITE. Hauerit *Haid.*, Nat. Abh. Wien, i. 101, 107, 4to, 1847.

Isometric; pyritohedral, figs. 2, 7, 6, 8, 44 (*O*, 3-$\frac{3}{2}$), 41 (*O*, *i*-3); the octahedral form most common. Cleavage: cubic imperfect. Crystals sometimes globularly clustered.

H.=4. G.=3·463, v. Hauer. Lustre metallic-adamantine. Color reddish-brown, brownish-black. Streak brownish-red.

Comp.—$Mn\,S^2$=Sulphur 53·7, manganese 46·3=100. Analysis by Patera (l. c., Pogg., lxx. 148):

S 53·64   Mn 42·97   Fe 1·30 $\ddot{Si}$ 1·20=99·11.

Pyr.—In the closed tube a sublimate of sulphur; in the open tube sulphurous acid, and becomes green. On charcoal gives sulphur; the roasted mineral reacts for manganese with the fluxes.

Obs.—From Kalinka, Hungary, in clay with gypsum and sulphur, in a region something like a solfatara, trachytic, and other eruptive rocks decomposing and adding to the clay, and the sulphur given off at the same time making depositions of sulphur and sulphids. One crystal found measures 1½ inches through.

77. CUBANITE. Cuban *Breith.*, Pogg., lix. 325, 1843. Cubanite *Chapman.*

Isometric. Massive. Cleavage cubic, and rather more distinct than in ordinary pyrites, Breith. Color between bronze and brass-yellow. Streak dark reddish-bronze, black. H.=4. G.=4·026—4·042 Br.; 4·169 Booth; 4·18 Smith.

Comp.—2 Fe, 1 Cu, 4 S=4 Fe, 1 Ɵu, 8 S=Ɵu S+Fe S+3 Fe S^2=2 *pyrite*+1 *chalcopyrite.* Cu S +$Fe^2 S^3$, Booth, which is the same with the preceding in its atomic proportions.

Analyses: 1, Eastwick (communicated by J. C. Booth); 2, Magee (ib.); 3, Stevens (ib.); 4, Scheidauer (Pogg., lxiv. 280); 5, J. L. Smith (Am. J. Sci., II. xviii. 381):

	S	Cu	Fe	S̈i
1.	39·01	19·80	38·01	2·30=99·12 Eastwick.
2.	39·35	21·05	38·80	1·90=101·10 Magee.
3.	39·05	20·12	38·29	2·85=100·81 Stevens.
4.	34·78	22·96	42·51	Pb *tr.*=100·25 Scheidauer.
5.	39·57	18·28	37·10	S̈i F̶e 4·23=99·13 Smith.

Breithaupt obtained in repeated trials 19 per cent. of copper. Smith in two other incomplete analyses found sulphur 39·20, 39·30, and copper 19·10, 19·00.

Pyr.—In the closed tube a sulphur sublimate; in the open, sulphurous acid. B.B. on charcoal gives sulphur fumes and fuses to a magnetic globule. The roasted ore reacts for copper and iron with the fluxes; with soda on charcoal gives a globule of metallic iron with copper.

Obs.—From Barracanao. Cuba.

78. CHALCOPYRITE. ? Χαλκίτις (fr. Cyprus) *Aristotle.* ? Χαλκίτις, Πυρίτης pt., *Dioscor.*, ? Chalcitis pt., Pyrites pt., *Plin.* Pyrites ærosus pt., Pyrites aureo colore, *Germ.* Geelkis o. Tetragonal; tetrahedral. $O \wedge 1\text{-}i = 135° \ 25'$; $a = 0{\cdot}98556$. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}3$; octahedral or tetrahedral, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, 1, $\frac{3}{2}$, 2, $1\text{-}i$, $\frac{3}{2}\text{-}i$, $2\text{-}i$; other planes, $\frac{1}{2}\text{-}3$, 5-5.

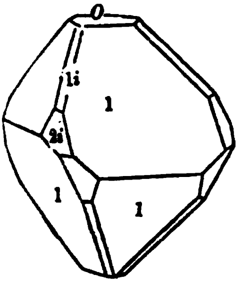
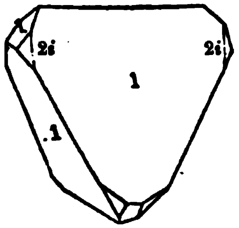
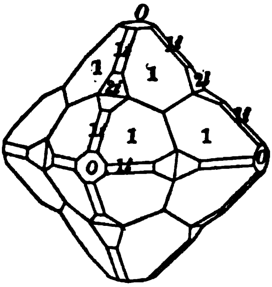
91



92



93



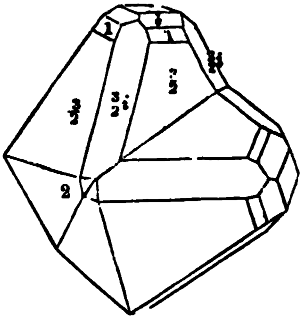
$O \wedge \frac{1}{2} = 145° \ 8'$
$O \wedge 1 = 125 \ 40$
$O \wedge 2 = 109 \ 44$

$O \wedge 2\text{-}i = 116° \ 54'$
$O \wedge \frac{3}{2}\text{-}i = 124 \ \ 5$
$1 \wedge 1$, pyr., $= 109 \ 53$

$2 \wedge 2$, pyr., $= 96° \ 33'$
$\frac{3}{2} \wedge \frac{3}{2}$, pyr., $= 100 \ 44$
$1 \wedge 1$, f. 92, $= 71 \ 20$ and $70 \ 7$

Cleavage: 2-*i* sometimes distinct; *O*, indistinct. Twins: composition-face (1) 1-*i*, f. 93, 94; in 93 repeated parallel to 4 terminal edges of a pyramid; also similar to fig. 39, through combinations of sphenoids; (2) the plane 1, similar to f. 50, also similar to f. 62, p. 21, but with the interpenetrating tetrahedrons of the forms in fig. 92; also somewhat similar to fig. 119, under tetrahedrite. Often massive and impalpable.

94



H.=3·5–4. G.=4·1–4·3. Lustre metallic. Color brass-yellow; subject to tarnish, and often iridescent. Streak greenish-black—a little shining. Opaque. Fracture conchoidal, uneven.

Comp.—A sulphid of copper and iron, containing 2 of copper, 2 of iron, and 4 of sulphur=Sulphur 34·9, copper 34·6, iron 30·5=100. Formula $\text{Ɵu}\,S + Fe\,S + Fe\,S^2 = 2\,(\frac{1}{2}\,\text{Ɵu} + \frac{1}{2}Fe)\,S + Fe\,S^2$, usually written $\text{Ɵu}\,S + Fe^2\,S^3$, the objection to which has already been mentioned (p. 33) Some analyses give other proportions; but probably from mixture with pyrita. These are indefinite mixtures of the two, and with the increase of the latter the color becomes paler.

This species, although tetragonal, is very closely isomorphous with pyrite, the variation from the cubic form being slight, the vertical axis being 0·98556 instead of 1.

Analyses: 1, H. Rose (Gilb., lxxii. 185); 2, Hartwall (Leonh. Handb., 646); 3, 4, E. Bechi (Am. J. Sci., II. xiv. 161); 5, D. Forbes (Ed. N. Phil. J., l. 278); 6, J. L. Smith (Am. J. Sci., II. xx. 249); 7, Joy (Lyc. N. H. N. York, viii. 125):

1. Sayn	S 35·87	Cu 34·40	Fe 30·47	quartz 0·27	=100·01	Rose.

6. Phenixville	36·10	32·85	29·93	Pb 0·35	=99·23	Smith.
7. Ellenville	36·65	32·43	31·25	" 0·30, $\ddot{S}i$ 0·20	=100·83	Joy.

Traces of selenium have been noticed by Kersten in an ore from Reinsberg near Freiberg; and that from Rammelsberg near Goslar must contain the same, it being one of the furnace products (Rammelsberg, Min. Chem., 120). Thallium is also present in some kinds, and more frequently present in this ore than in pyrite.

Other analyses: Malaguti and Durocher (Ann. des M., IV. xvii. 229).

Pyr., etc.—In the closed tube decrepitates, and gives a sulphur sublimate; in other reactions like cubanite. Dissolves in nitric acid, excepting the sulphur, and forms a green solution; ammonia in excess changes the green color to a deep blue.

Obs.—Chalcopyrite is the principal ore of copper at the Cornwall mines, and 10,000 to 12,000 tons of pure copper are smelted annually from 150,000 to 160,000 tons of ore. It is there associated with tin ore, galenite, bornite, chalcocite, tetrahedrite, and blende. The copper beds of Fahlun in Sweden, are composed principally of this ore, which occurs in large masses, surrounded by a coating of serpentine, and imbedded in gneiss. At Rammelsberg, near Goslar in the Harz, it forms a bed in argillaceous schist, and is associated with pyrite, galenite, blende, and minute portions of silver and gold. The Kurprinz mine at Freiberg affords well-defined crystals. It occurs also in the Bannat, Hungary, and Thuringia; in Scotland in Kirkcudbrightshire, Perthshire and elsewhere; in Tuscany (analyses 3, 4); in South Australia; in fine crystals at Cerro Blanco, near Copiapo, Chili.

In *Maine*, at the Lubec lead mines; at Dexter. In *N. Hamp.*, at Franconia, in gneiss; at Unity, on the estate of Jas. Neal; Warren, on Davis's farm; at Eaton, 2 m. N.E of Atkins's tavern; Lyme, E. of E. Village; Haverhill, etc. In *Vermont*, at Stafford, Corinth, Waterbury, Shrewsbury. In *Mass.*, at the Southampton lead mines; at Turner's falls on the Connecticut, near Deerfield, and at Hatfield and Sterling. In *Connecticut*, at Bristol and Middlotown, sometimes in crystals. In *New York*, at the Ancram lead mine; five miles from Rossie, beyond De Long's mills at the Rossie lead mines, in crystals; in crystals and massive near Wurtzboro', Sullivan Co.; very large crystals and massive at Ellenville, Ulster Co. In *Pennsylvania*, at Phenixville; at Pottstown, Chester Co. (Elizabeth mine). In *Maryland*, in the Catoctin mts.; between New market and Taneytown; near Finksbury, Carroll Co., abundant (Patapsco and other mines), with bornite, carrollite, and malachite. In *Virginia*, at the Phenix copper mines, Fauquier Co., and the Walton gold mine, Louisa Co. In *N. Carolina*, near Greensboro', abundant massive (Fenress or North Carolina, and Macculloch mines), along with spathic iron in a quartz gangue. In *Tennessee*, 30 miles from Cleveland, in Polk Co. (Hiwassee mines), with black copper and pyrites.

In *Cal.*, in different mines along a belt between Mariposa Co. and Del Norte Co., on west side of, and parallel to, the chief gold belt; occurring massive in Calaveras Co., at Union, Keystone, Empire, Napoleon, Campo Seco, and Lancha Plana mines, and in crystals on Domingo Creek; in Mariposa Co., at the La Victoire and Haskell claims, and on the Chowchillas river; in Amador Co., at the Newton mine; in El Dorado Co., at the Cosumnes, Hope Valley, Bunker Hill, El Dorado, Excelsior mines; in Plumas Co., at the Genesee and Cosmopolitan mines.

In *Canada*, in Perth and near Sherbrooke; extensively mined at Bruce mines, on Lake Huron

The Cornwall chalcopyrite is not a rich ore; what is picked for sale at Redruth rarely yielding 12, generally only 7 or 8, and occasionally but 3 or 4 per cent. of metal. Its richness may in general be judged of by the color; if of a fine yellow hue, and readily yielding to the hammer, it may be considered a good ore; but if hard, and pale-yellow, it is poor from admixture with pyrite.

Readily distinguished from pyrite, which it somewhat resembles, by its inferior hardness; it may be cut by the knife, while pyrite will strike fire with steel. The effects of nitric acid are also different. Differs from gold in being brittle, on which account it cannot be cut off in slices, like the latter metal; and, moreover, gold is not attacked by nitric acid.

Occurs as a furnace product near Goslar.

Alt.—Changes on exposure with moisture, especially if heated, to a sulphate. Malachite, covellite, chrysocolla, black copper, chalcocite, and oxyd of iron, are other forms into which it is sometimes altered.

Named from χαλκός, *brass*, and *pyrites*, by Henckel, who observes in his Pyritology (1725) that chalcopyrite is a good distinctive name for the ore. Aristotle calls the copper ore of Cyprus *chalcitis*; and Dioscorides uses the same word; but what ore was intended is doubtful. There is no question that copper-pyrites was included by Greek and Latin authors under the name *pyrites* (q. v., p. 64).

79. BARNHARDTITE. Genth, Am. J. Sci., II. xix. 17, 1855, xxviii. 248.

Compact massive.

H.=3·5. G.=4·521. Lustre metallic. Color bronze-yellow. Streak grayish-black, slightly shining. Fracture conchoidal, uneven. Brittle. Tarnishes easily, giving pavonine tints, or becoming pinchbeck-brown.

Comp.—$2\,\text{Ɵu}\,S+Fe\,S+Fe\,S^2$=1 chalcopyrite+1 chalcocite=Sulphur 30·5, copper 48·2, iron 21·3. **Analyses**: 1–3, W. J. Taylor, F. A. Genth, and P. Keyser (l. c.); 4, Genth (priv. contrib.):

	S	Fe	Cu	
1. Barnhardt's Land	29·40	22·23	47·61, Ag *tr.*	Taylor.
2. Pioneer Mills	29·76	22·41	46·69	Genth.
3. " "	30·50	21·08	48·40	Keyser.
4. Bill Williams' Fork	28·96	20·44	50·41	Genth.

In another ore from Barnhardt's land, Taylor found (l. c.) S 32·9, Fe 28·4, Cu 40·2, corresponding to $8\,S+4\,Fe+2\tfrac{1}{2}\,\text{Ɵu}$.

Pyr., etc.—B.B. gives sulphurous fumes, and fuses easily to a magnetic globule. With borax reactions for copper and iron.

Obs.—Occurs in N. Carolina with other copper ores, at Dan Barnhardt's land, Pioneer Mills, Phenix mine, and Vanderburg mine, in Cabarrus Co.; also near Charlotte, Mecklenburg Co.; at Bill Williams' Fork, in California, with chalcopyrite, etc.

It may be a chalcopyrite, partly altered to copper-glance (chalcocite), as would be inferred from Dr. Genth's later observations.

(A) HOMICHLIN Breithaupt (B. H. Ztg., xvii. 385, 424, 1858, xviii. 65, 321) is closely related to the preceding, and may be chalcopyrite partly altered to bornite. Occurs in tetragonal octahedral crystals, but mostly massive; H.=4—5, G.=4·472—4·480; color more bronze-like than in chalcopyrite; streak black.

Analysis by Richter (l. c., xviii. 321): S 30·21, Fe 25·81, Cu 43·76=$3\,\text{Ɵu}\,S+2\,Fe\,S+Fe^2\,S^3$, or $3\,\text{Ɵu}\,S+3\,Fe\,S+Fe\,S^2$, corresponding to 1 of *chalcopyrite*, 2 of *chalcocite*, and 2 of *pyrrhotite*, or to 1 of chalcopyrite and 2 of bornite.

Occurs with malachite and other copper ores at Plauen in Voigtland; also said to occur, by Breithaupt, in Bavaria, Duchies of Hesse and Nassau, Silesia, the Harz, at Rheinbreitenbach on the Rhine, in Algeria, in Chili at Remolinos and Tocopilla, and in Japan.

Ducktownite is a blackish copper ore from Ducktown, Tenn., named by Shepard, who found in it 30·76 iron, 26·04 copper, with 43·20 of *undetermined*. G. J. Brush has shown that it is not homogeneous, and only a mixture, grains of pyrite being visible through the mass, and also a softer gray mineral, which is probably chalcocite See Rep. on Mt. Pisgah Copper Mine, N. Haven, 1859, and Am. J. Sci., II. xxviii. 129, 1859.

80. **STANNITE.** Geschwefeltes Zinn (fr. Cornwall) *Klapr.*, Schriften Nat. Fr. Berlin, vii. 169, 1787, Beitr., ii. 257, 1797, v. 228, 1810. Zinkies *Wern.*, Bergm. J., 1789, 385, 397. Tin Pyrites *Kirw.*, ii. 300, 1796. Sulphuret of Tin; Bell Metal Ore. Etain sulfuré *Fr.* Stannine *Beud.*, Tr., ii. 416, 1832.

Prboably tetragonal, and hemihedral like chalcopyrite, Kenngott. Cleavage: parallel to the faces of the cube and dodecahedron indistinct. Commonly massive, granular, and disseminated.

H.=4. G.=4·3–4·522; 4·506, fr. Zinnwald, Rammelsberg. Lustre metallic. Streak blackish. Color steel-gray to iron-black, the former when pure; sometimes a bluish tarnish; often yellowish from the presence of chalcopyrite. Opaque. Fracture uneven. Brittle.

Comp.—2 (Cu, Fe, Zn) S + Sn S^2, which, the ratio of Cu, Fe, Zn, being 2 : 1 : 1, corresponds to, Sulphur 29·6, tin 27·2, copper 29·3, iron 6·5, zinc 7·5=100. The ratio between the sulphur of the two terms is 1 : 1, as in chalcopyrite. Analyses: 1, Klaproth (Breitr., v. 228); 2, Kudernatsch (Pogg., xxxix. 146); 3, Johnston (Rep. G. Cornwall, etc., 1839); 4, Mallet (Am. J. Sci., II xvii. 33); 5, Rammelsberg (Pogg., lxxxviii. 607):

	S	Sn	Cu	Fe	Zn
1. Wheal Rock	30·5	26·5	30·0	12·0	——=99·0 Klaproth.
2. "	29·64	25·55	29·39	12·44	1·77, gangue 1·02=99·81 Kud.
3. St. Michael's Mt.	29·929	31·618	23·549	4·791	10·113=100 Johnston.
4. "	29·46	26·85	29·18	6·73	7·26, gangue 0·16=99·64 Mal.
5. Zinnwald	29·05	25·65	29·38	6·24	9·68=100 Rammelsberg.

Pyr., etc.—In the closed tube decrepitates, and gives a faint sublimate; in the open tube sulphurous acid, and a sublimate of oxyd of tin quite near the assay. B.B. on charcoal fuses to a globule, which in O.F. gives off sulphur, and coats the coal with white oxyd of tin; the roasted mineral treated with borax gives reactions for iron and copper.

Decomposed by nitric acid, affording a blue solution, with separation of sulphur and oxyd of tin.

Obs.—Formerly found at Wheal Rock, Cornwall, and at Carn Brea, where it constituted a considerable vein, and was accompanied by pyrite, blende, and other minerals; more recently in considerable quantity in granite at St. Michael's Mount, where it is sold as an ore of copper; also at Stenna Gwynn, St. Stevens, and at Wheal Primrose, Wheal Scorrier, and occasionally at Botallack mine, St. Just; also at the Cronebane mine, Co. Wicklow, in Ireland; Zinnwald, in the Erzgebirge, with blende and galenite. It frequently has the appearance of bronze or bell metal, and hence the name *bell-metal ore.*

81. **LINNÆITE.** Kobolt med Jern och Svafelsyra (fr. Bastnaes) *G. Brandt*, Ak. H. Stockh., 119, 1746. Kobalt med förvswafladt Järn, Cobaltum Ferro Sulphurato mineralisatum, *Cronst.*, 213, 1758. Cobaltum pyriticosum *Linn.*, 1768; *de Born*, Lithoph., i. 144, 1772. Mine de Cobalt sulfureuse *de Lisle*, iii. 134, 1783. Kobalt-Glanz pt. *Wern.*, *Kirwan*, *etc.* Svafelbunden Kobolt *Hisinger*, Afh., iii. 316, 1810. Kobaltkies *Hausm.*, Handb., 158, 1813. Schwefelkobalt. Sulphuret of Cobalt; Cobalt Pyrites. Cobalt sulfuré *Fr.* Koboldine *Beud.*, Tr., ii. 417, 1832. Linneit *Haid.*, Handb., 560, 1845. Kobaltnickelkies [not Kobaltkies] *Ramm.*; Siegenite (fr Müsen) *Dana*, Min., 687, 1850.

Isometric. Figs. 2, 6, 7. Cleavage: cubic, imperfect. Twins: composition-face octahedral. Also massive, granular to compact.

H.=5·5. G.=4·8–5. Lustre metallic. Color pale steel-gray, tarnishing copper-red. Streak blackish-gray. Fracture uneven or subconchoidal.

Comp., Var.—2 Co S + Co S^2=Sulphur 42·0, cobalt 58·0=100; but having the cobalt replaced partly by nickel or copper.

Var. 1. *Cupriferous;* LINNÆITE Haid. (l. c.). Ore from Bastnaes. The copper has been attributed to mixed chalcopyrite; but, in view of the composition of carrollite, this is probably not true of all of it. The name *linnæite*, after Linnæus, was given distinctively by Haidinger to the *Bastnaes* mineral (l. c.).

2. *Niccoliferous; Nickel-Linnæite* SIEGENITE Dana (l. c.). Ore from Müsen, near Siegen and elsewhere. The specimens from Müsen afforded Rammelsberg, in his recent analysis (No. 5), 14·60 of nickel; and he shows that the earlier analyses are erroneous, owing to the fact that a method of separating nickel and cobalt completely was not known when the analyses were made.

Analyses. 1, Hisinger (Afhandl., iii. 319); 2, Wernekink (Schw. J., xxxix. 306, and Leonh. ZS. f. Min., 1826); 3, Schnabel (Ramm., 4th Suppl., 117); 4, Ebbinghaus (ib.); 5, Rammelsberg (J. pr. Ch., lxxxvi. 340); 6–8, Genth (Am. J. Sci., II. xxiii. 419):

6. Mineral Hill, *Sieg.*	39·70*	25·69	29·56	1·96	2·23, Insol. 0·45=99·59 Genth.
7. " *Sieg.*	41·15	[50·76]		3·20	3·68, Insol. 1·26=100 Genth. [Genth.
8. Missouri, *Sieg.*	41·54	21·34	30·53	3·37	——, Pb 0·39, Cu, Sb *tr.*, Insol. 1·07=98·24

Pyr., etc.—The variety from Müsen gives, in the closed tube, a sulphur sublimate; in the open tube, sulphurous fumes, with a faint sublimate of arsenous acid. B.B. on charcoal gives arsenical and sulphurous odors, and fuses to a magnetic globule. The roasted mineral gives with the fluxes reactions for nickel, cobalt, and iron. Soluble in nitric acid, with separation of sulphur.

Obs.—In gneiss, with chalcopyrite, at Bastnaes, near Riddarhyttan, Sweden; at Müsen, near Siegen, in Prussia, with heavy spar and spathic iron; at Siegen (*siegenite*), in octahedrons; at Mine la Motte, in Missouri, mostly massive, sometimes octahedral and cubo-octahedral crystals; and at Mineral Hill, in Maryland, in a vein in chlorite slate, with chalcopyrite, bornite, blende, pyrite, etc.

Alt.—Occurs altered to yellow earthy cobalt so-called (*gelb Erdkobalt*), which is a mixture of erythrite and pitticite.

82. CARROLLITE. *Faber*, Am. J. Sci., II. xiii. 418, 1852.

Isometric. Rarely in octahedrons. Massive. Fracture subconchoidal or uneven.

H.=5·5. G.= 4·85, Smith and Brush. Lustre metallic. Color light steel-gray, with a faint reddish hue.

Comp.—Cu S + Co^2 S^3: or its equivalent Ɵu S + Co S + Co S^2 (obtained by doubling the number of atoms), which may be written 2 ($\frac{1}{2}$ Ɵu + $\frac{1}{2}$ Co) S + 3 Co S^2: analogous to Cuban. Analyses 1–3, Smith and Brush (Am. J. Sci., II. xvi. 367); 4, Genth (ib., xxiii. 418):

	S	Co	Ni	Fe	Cu	As

4. "	41·71	38·70	1·70	0·46	17·55,	quartz 0·07=100·19 G.

Faber obtained in an incorrect analysis (l. c.) S 27·04, Co 28·50, Ni 1·50, Fe 5·31, Cu 32·99, As 1·81, silica 2·15=99·30.

Pyr.—Like siegenite, except that the roasted mineral reacts for copper with the fluxes.

Obs.—In Carroll Co., Maryland, at Patapsco mine, near Finksburg; and also at Springfield mine, associated and mixed with chalcopyrite and chalcocite.

This species may prove to be identical with the Bastnaes linnæite or true linnæite), on a new analysis of the latter, both being cupriferous.

83. SMALTITE. ? Cobaltum cineraceum *Agric.*, 459, 1529. Koboltmalm, Koboltglantz, Minera Cobalti cinerea, Cobaltum arsenico mineralisatum, pt. (Cobaltite here included), *Wall.*, 231 1747. ? Cobaltum Ferro et Arsenico mineralisatum, Glants-Cobalt (fr. Schneeberg), *Cronst.*, 212 1758. Mine de Cobalt grise *De Lisle*, Crist., 333, 1772; Mine de Cobalt arsenicale *De Lisle*, iii 123, 1783. Weisser Speisskobold, Grauer Speisskobold, *Wern.* Gray Cobalt ore *Kirw.*, 1796 Tin-white cobalt. Speiskobalt *Hausm.*, Handb., 155, 1813. Smaltine *Beud.*, Tr., ii. 584, 1852.

Isometric. Observed planes: *O*, 1, 2-2, *I*, also an undetermined tetrahexahedron. Figures 1, 2, 5, 6, 8, 9. Cleavage: octahedral, distinct. Cubic, in traces. Also massive and in reticulated and other imitative shapes.

H.=5·5—6. G.=6·4 to 7·2. Lustre metallic. Color tin-white, inclining, when massive, to steel-gray, sometimes iridescent, or grayish from tarnish. Streak grayish-black. Fracture granular and uneven. Brittle.

Comp., Var.—For typical kind (Co, Fe, Ni) As^2= (if Co, Fe, and Ni be present in equal parts) Arsenic 72·1, cobalt 9·4, nickel 9·5, iron 9·0=100. It is probable that nickel is never wholly absent, although not detected in some of the earlier analyses; and in some kinds it is the principal metal. The varieties based on the proportions of cobalt, nickel, and iron, are the following:

Var. 1. *Cobaltic*; SMALTINE. Contains little nickel or iron.

2. *Niccoliferous*; CHLOANTHITE *Breith.* (B. H. Ztg., iv. 1845; Weissnickelkies pt., Weissnickelerz, Arsenik-Nickel, *Germ.*; White Nickel; Rammelsbergit *Haid.*, Handb., 560, 1845; Chathamite *Shep.*, Am. J. Sci., xlvii. 351, 1844). Contains much nickel, the cobalt simetimes nearly wanting.

3. *Ferriferous*; SAFFLORITE *Breith.* (Grauer Speiskobold *Wern.*; Eisenkobalterz *Hausm.*; Eisenkobaltkies *v. Kob.*). Contains over 10 p. c. of iron with cobalt, or with cobalt and nickel.

But the atomic proportion of arsenic and other elements often varies much from the normal above stated, and without correspondence with the three groups just pointed out. These variations lead to the following groups, as distinguished by Rammelsberg, which, however, blend more or less with one another:

A. Composition $R\,As^2$, with R=Co, Fe, and some Ni. Includes some of Nos. 1, 2, and 3, above.

B. $R\,As^2$, with R=Ni, Fe, and some Co. Includes most *chloanthite*, No. 2. Anal. 6 to 12.

C. $R\,As+R\,As^2$. Anal. 13 to 15. Includes some of Nos. 2 and 3.

D. $R\,As^3+2\,R\,As^2$. Anal. 16 to 21. Includes some of 1 and 2. In this last the arsenic constitutes 73—76 p. c., and the mineral approximates to *Skutterudite*.

Analyses: Series A. 1, Varrentrapp (Pogg., xlviii. 505); 2, Hofmann (Pogg., xxv. 485); 3, Kobell (Grundz. Min., 300); 4, Klauer (Ramm., 5th Suppl., 225); 5, Lange (Ramm., Min. Ch., 24).—Series B. 6, Booth (Am. J. Sci., xxix. 241); 7, Rammelsberg (J. pr. Ch., lv. 486); 8, 9, id. (1st Suppl., 15); 10, F. Marian (Vogl's Min. Joach., 158); 11, C. U. Shepard (Am. J. 21. Joachimsthal	74·52	11·72	1·81	5·26	1·00, S 1·81=99·72 Marian.

J. L. Smith found over 8 p. c. of copper in a smaltine from Atacama, his analysis affording (Gilliss's Exped., ii. 102) As 70·85, Co 24·18, Ni 1·23, Fe 4·05, Cu 8·41, S 0·08=100·75.

Pyr., etc.—In the closed tube gives a sublimate of metallic arsenic; in the open tube a white sublimate of arsenous acid, and sometimes traces of sulphurous acid. B.B. on charcoal gives an arsenical odor, and fuses to a globule, which, treated with successive portions of borax-glass, affords reactions for iron, cobalt, and nickel.

Obs.—Usually occurs in veins, accompanying ores of cobalt or nickel, and ores of silver and copper; also, in some instances, with niccolite and arsenopyrite; often having a coating of annabergite.

Occurs with silver and copper at Freiberg, Annaberg, and particularly Schneeberg in Saxony; at Joachimsthal in Bohemia, the reticulated varieties are frequently found imbedded in calc spar, and also at Wheal Sparnon in Cornwall; at Riechelsdorf in Hesse, in veins in the copper schist; at Tunaberg in Sweden; Allemont in Dauphiné; at the silver mines of Tres Puntas and others in Chili, but only in small quantities. Also in crystals at Mine La Motte, Missouri. See analyses above for the varieties at these localities.

At Chatham, Conn., the chloanthite (chathamite) occurs in mica slate, associated generally with arsenopyrite and sometimes with niccolite.

This species and the cobaltite were confounded by the mineralogists of last century; and although right chemical distinctions were early indicated by those of Sweden, doubts continued until the analyses by John and Stromeyer in 1811 and 1817. Romé de Lisle brought out and figured correctly the crystallographic distinctions in 1772 and 1783; but the value of his determinations were not generally appreciated.

Alt.—Occurs altered to erythrite (arsenate of cobalt), a change due to the oxydation of the arsenic and cobalt on exposure to moisture.

84. SKUTTERUDITE. Tesseral-Kies, Hartkobaltkies, *Breith.*, Pogg., ix. 115, 1827. Arsenikkobaltkies *Scheerer*, Pogg., xlii. 546, 1837. Hartkobalterz *Hausm.*, Handb., 69, 1847. Skutterudit *Haid.*, Handb., 560, 1845. Modumite *Nicol*, Min., 457, 1849.

Isometric. Observed planes *O*, *I*, 1, 2, $\frac{3}{2}$, 2-2, *i*-3, 2-$\frac{3}{2}$. Figs. 1, 2, 3, 10. Cleavage: cubic, distinct; *I*, in traces. Also massive granular.

H.=6. G.=6·74–6·84. Lustre bright metallic. Color between tin-white and pale lead-gray, sometimes iridescent.

Comp.—$Co\,As^3$=Arsenic 79·2, cobalt 20·8=100. Analyses: 1, Scheerer (l. c.); 2, 3, Wöhler (Pogg., xliii. 591):

1. Skutterud	As 77·84	Co 20·01	Fe 1·51	S 0·69=100·05 Scheerer.
2. " *cryst.*	79·2	18·5		1·3=99·0 Wöhler.
3. " *mass.*	79·0	19·5		1·4=99·9 Wöhler.

Pyr.—Reactions like those of smaltite, but gives a more copious sublimate of metallic arsenic in the closed tube.

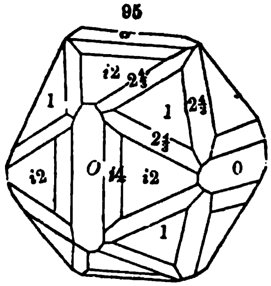
Obs.—From Skutterud, near Modum, in Norway, in a hornblendic gangue in gneiss, with sphene and cobaltite, and the crystals sometimes implanted on those of cobaltite.

85. COBALTITE. Cobaltum cum ferro sulfurato et arsenicato mineralisatum, Glants-Kobolt pt. (fr. Tunaberg), *Cronst.*, 213, 1758. Mine de Cobalt blanche *de Lisle*, Crist., 334, 1772. Mine de Cobalt arsenico-sulfureuse *de Lisle*, Crist., iii. 129, 1783. Glanz-Kobold *Wern.* Kobalt-Glanz *Germ.* Cobalt gris pt. *H.* Glance Cobalt; Bright-White Cobalt. Glanzkobaltkies *Glock.*, Grundr., 1831. Cobaltine *Beud.*, Tr. ii. 450, 1832.

Isometric; pyritohedral. Observed planes, as in the annexed figure;

f. 46, 47. Cleavage: cubic, perfect. Planes *O* striated. Also massive, granular or compact.

95



H.=5·5. G.=6—6·3. Lustre metallic. Color silver-white, inclined to red; also steel-gray, with a violet tinge, or grayish-black when containing much iron. Streak grayish-black. Fracture uneven and lamellar. Brittle.

Comp., Var.—$\mathrm{Co\,S^2+Co\,As^2}$, or $\mathrm{Co\,(S,\,As)^2}$=Sulphur 19·3, arsenic 45·2, cobalt 35·5=100. The cobalt is sometimes largely replaced by iron, and sparingly by copper.

Var. 1. *Ordinary.* Contains little iron. Anal. 1—6.

2. *Ferriferous*; FERROCOBALTITE (Stahlkobalt *Ramm.*, 4th Suppl., 116, 5th Suppl., 148, 1853; Ferrocobaltine *Dana*, Min., 58, 1854). Contains much iron (anal. 7—9); from the Hamberg mine, Siegen

Analyses: 1, Stromeyer (Schw. J., xix. 336); 2, Schnabel (Ramm., 3d Suppl., 65); 3, Huberdt (Ramm., 4th Suppl., 116); 4, Patera (ib.); 5, Ebbinghaus (ib.); 6, 7, Schnabel (ib.); 8, Schnabel (ib., 5th Suppl., 149); 9, Heidingsfeld (ib.):

The analyses of supposed cobaltite by Patera and Huberdt are given under ALLOCLASITE.

Pyr., etc.—Unaltered in the closed tube. In the open tube, gives sulphurous fumes, and a crystalline sublimate of arsenous acid. B.B. on charcoal gives off sulphur and arsenic, and fuses to a magnetic globule; with borax a cobalt-blue color. Soluble in warm nitric acid, separating arsenous acid and sulphur.

Obs.—Occurs at Tunaberg, Riddarhyttan, and Hokansbö, in Sweden, in large, splendid, well-defined crystals; also at Skutterud in Norway. Other localities are at Querbach in Silesia, Siegen in Westphalia, and Botallack mine, near St. Just, in Cornwall. The most productive mines are those of Vena in Sweden, where it occurs in mica slate; these mines were first opened in 1809.

This species and smaltite afford the greater part of the smalt of commerce. It is also employed in porcelain painting.

86. GERSDORFFITE. Niccolum Ferro et Cobalto Arsenicatis et Sulphuratis mineralisatum, Kupfernickel, pt. (*white* var. fr. Loos), *Cronst.*, 218, 1758, Ak. H. Stockh., 1751, 1754. [The species later taken for Kupfernickel and Cobalt ore, until 1818.] Nickelglanz, Weisses Nickelerz, *Pfaff*, Schw. J., xxii. 260, 1818; *Berz.*, Ak. H. Stockh., 1820. Sulfo-arséniure de nickel *Beud.*, 1824 Nickelarsenikglanz, Nickelarsenikkies, Arseniknickelglanz, *Germ.* Nickel Glance. Disomose *Beud.*, Tr., ii. 448, 1832. Tombazite pt. *Breith.*, J. pr. Ch., xv. 330, 1838. Gersdorffit (fr. Schladming) pt. *Löwe*, Pogg., lv. 503, 1842. Amoibit pt. *v. Kob.*, J. pr. Ch., xxxiii. 402, 1844.

Isometric; pyritohedral. Observed planes *O*, 1, *i*-2. Figs. 2, 6, 7, 46. Cleavage: cubic, rather perfect. Also lamellar and granular massive.

H.=5·5. G.=5·6—6·9. Lustre metallic. Color silver-white—steel-gray, often tarnished gray or grayish-black. Streak grayish-black. Fracture uneven.

Comp., Var.—Normal, $\mathrm{Ni\,S^2+Ni\,As^2}$, or $\mathrm{Ni\,(S,\,As)^2}$=Arsenic 45·5, sulphur 19·4, nickel 35·1=100. But the composition varies in atomic proportions rather widely, and the species is not yet fully understood.

Var. 1. *Normal.* Having the above composition.

2. Löwe's *gersdorffite* (No. 10) affords 1 [$Ni\,S^2+Ni\,As^2$] + ½ niccolite (p. 60), corresponding to At. ratio for As, S, Ni, 3 : 2 : 3. Löwe deduced 4 : 3 : 4, the formula from which would differ only in the last member being ⅓ niccolite. Anal. 9 falls in with this formula.

3. Von Kobell's *amoibite* (anal. 17) afforded him, 4 As + 3 S + 4 Ni = Arsenic 47·4, sulphur 15·2, nickel 37·4. 4 As + 3 S + 4½ Ni is nearer the analysis. The mineral occurs at Lichtenberg in the Fichtelgebirge in light steel-gray octahedrons, having H. = 4.

4. H. = 4. Pless's analyses (Nos. 12–14), and also Bogen's of the ore of Siegen (No. 15), correspond to 2 $Ni\,S+Ni\,As^2$. This ore may be named *plessite*.

5. *Dobschauite*. Anal. 18 corresponds to At. ratio for As, S, (Ni, Fe, Co), 2 : 1 : 2, giving the formula 1 [$R\,S^2+R\,As^2$] + 2 niccolite.

Analyses: 1, Berzelius (l. c.); 2, Rammelsberg (Pogg., lxviii. 511); 3, 4, Schnabel (Verh. Ver. Bonn, viii. 307, Ramm. Min.-Ch., 65); 5, Bergemann (J. pr. Ch., lxxv. 244); 6, Döbereiner (Schw. J., xxvi. 270); 7, Rammelsberg (Handw., ii. 14); 8, Heidingsfeld (Ramm., 5th Suppl. 174); 9–11, Löwe (Ramm., 2d Suppl., 102, Pogg., lv. 503); 12–14, Pless (Ann. Ch. Pharm., li. 250); 15, Bogen (B. H. ^{a} with some Cu. ^{b} by loss. ^{c} with some Co.

Pyr., etc.—In the closed tube decrepitates, and gives a yellowish-brown sublimate of sulphid of arsenic. In the open tube yields sulphurous fumes, and a white sublimate of arsenous acid. B.B. on charcoal gives sulphurous and garlic odors and fuses to a globule, which, with borax-glass gives at first an iron reaction, and, by treatment with fresh portions of the flux, cobalt and nickel are successively oxydized.

Decomposed by nitric acid, forming a green solution, with separation of sulphur and arsenous acid.

Obs.—Occurs at Loos in Helsingland, Sweden; in the Albertine mine, near Harzgerode in the Harz, with chalcopyrite, galenite, calcite, fluor-spar, and quartz; at Schladming in Styria; Kamsdorf in Lower Thuringia; Haueisen, near Lobenstein, Voigtland; at the quicksilver mine (anal. 4) and at Pfingstweise (anal. 5), near Ems. Also found as an incrustation of cubes, with planes 1 and 2-2, on decomposed galenite and blende, at Phenixville, Pa.

87. ULLMANNITE. Nickelspiesglaserz (fr. Siegen) *Ullmann* (his discov. in 1803), Syst.-Tab., 166, 379, 1814. Nickelspiessglanzerz *Hausm.*, Handb., 192, 1813. 5 Harzgerode	2·65	50·84	17·38	29·43, Fe 1·83=102·13 Ramm.

Pyr., etc.—In the closed tube gives a faint white sublimate. In the open tube sulphurous and antimonous fumes, the latter condensing on the walls of the tube as a white non-volatile sublimate. B.B. on charcoal fuses to a globule, boils, and emits antimonous vapors, which coat the coal white: treated with borax-glass reacts like gersdorffite. Some varieties contain arsenic. Decomposed by nitric acid, forming a green solution, with separation of sulphur and antimonous acid.

Obs.—Occurs in the Duchy of Nassau, in the mines of Freusburg, with galenite and chalcopyrite; in Siegen, Prussia; at Harzgerode and Lobenstein.

Rammelsberg calls an ore from the Harz *bournonit-nickelglanz*. It occurs in cubes; H.=4·5 G.=5·635—5·706. Analysis (Pogg., lxxvii. 254):

As	Sb	S	Ni	Co	Pb	Cu	Fe
28·00	19·53	16·86	27·04	1·60	5·13	1·33	0·51=100

It comes from Wolfsberg in the Harz.

88. CORYNITE. Korynit *v. Zepharovich*, Ber. Ak. Wien, li. 117, 1865.

Isometric. In octahedrons, with convex faces. Also in globular groups. H.=4·5—5. G.=5·994; 5·95—6·029, v. Z. Lustre metallic. Color silver-white, inclined to steel-gray on fresh fracture; streak black. Opaque. Fracture uneven.

Comp.—$Ni\ S^2 + Ni\ (As, Sb)^2$, or like ullmannite, and differing in that the arsenic present exceeds in amount the antimony. Analysis: v. Payer (l. c.):

As	Sb	S	Ni	Fe
37·83	13·45	17·19	28·86	1·98=99·31

Pyr., etc.—In the open tube affords sulphurous acid and a crystalline white sublimate. In the mattrass also finally a narrow yellowish-red and a broader yellow zone. B.B. on charcoal fuses easily at surface, yielding fumes of sulphurous acid and antimony. With borax-glass reactions of iron, cobalt, and finally nickel, with an arsenical odor.

Obs.—From Olsa, in Carinthia, with bournonite; crystals about 2½ mm. through.

Named from Κορύνη, *a club*.

89. LAURITE. Laurit *Wöhler*, Ann. Ch. Pharm., cxxxix. 116.

Isometric. In small octahedrons, with faces of the cube, and 2-2, *i*-2. Cleavage: octahedral distinct.

H. above 7. G.=6·99, v. Waltershausen. Lustre metallic, bright. Color dark iron-black; powder dark-gray. Brittle.

Comp.—Sulphid of osmium and ruthenium. Perhaps $12\ Ru^2 S^3 + Os\ S^4$, or $Ru\ S^2\ [+\tfrac{1}{16} Ru^4 Os]$ =Sulphur 32·12, Ru 62·88, Os 5·00=100. Analysis: Wöhler (l. c.):

S 31·79 [Os 3·03] Ru 65·18=100

The osmium was determined by the loss, and the ruthenium was not wholly pure from it, the amount used for analysis having been but 0·3145 grain.

Pyr., etc.—Heated it decrepitates. B.B. infusible, giving first sulphurous and then osmic acid fumes. Not acted upon by aqua regia, or by heating with bisulphate of potash.

Obs.—From the platinum washings of Borneo. Found among fine-grained platinum which had been brought from Borneo.

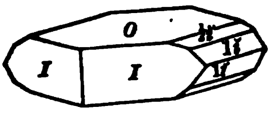
Observed planes.

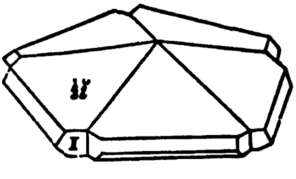
Cleavage: I rather perfect; $1\text{-}\bar{i}$ in traces. Twins: plane of composition I, sometimes consisting of five individuals, united by the acute lateral angle (f. 97); also others with composition parallel to $1\text{-}\bar{i}$. Also globular, reniform, and other imitative shapes—structure straight columnar; often massive, columnar, or granular.

H.=6–6·5. G.=4·678–4·847. Lustre metallic. Color pale bronze-yellow, sometimes inclined to green or gray. Streak grayish or brownish-black. Fracture uneven. Brittle.

96



97



Comp., Var.—Fe S^2, like pyrite.

The varieties that have been recognized depend mainly on state of crystallization.

1. *Radiated* (*Strahlkies*): Radiated; also the simple crystals.
2. *Cockscomb P.* (*Kammkies*): Aggregations of flattened crystals into crest-like forms.
3. *Spear P.* (*Speerkies*): Twin crystals, with reëntering angles a little like the head of a spear in form.
4. *Capillary* (*Haarkies*): In capillary crystallizations.
5. *Hepatic P.* (*Leberkies* and *Pyrites fuscus* pt.): The massive of dull colors, being named from ἧπαρ, *liver*; but including, among the older mineralogists especially, brown specimens of any pyrite, altered more or less to limonite.
6. *Cellular P.* (*Zellkies*): In cellular specimens, formed by the incrustation of the crystals of other minerals that have disappeared; partly pyrite.
7. *Arsenical*: Nearly white in color (in part *kyrosite* Breith., and *weisskupfererz*); contains a trace of arsenic.

Analyses: 1, Hatchett (Phil. Trans., 325, 1804); 2, 3, Berzelius (Schw. J., xxvii. 37): 4, Scheidhauer (Pogg., lxiv. 282); 5, Trapp (B. H. Ztg., xxiii. 55):

	Fe	S
1.	46·4	53·6=100 Hatchett.
2.	45·66	54·34=100 Berzelius.
3. *Spear P.*	45·07	52·35, Mn 0·70, $\ddot{S}i$ 0·80=99·92 Berzelius.
4. *Kyrosite*	45·60	53·05, Cu 1·41, As 0·93=100·99 Scheidhauer.
5. Münsterthal, Baden	46·93	51·95=98·88 Trapp.

Pyr.—Like pyrite. Very liable to decomposition; more so than pyrite.

The *kyrosite* Breith., called also *weisskupfererz*, Char., 1823, 111, 246, and *arsenid of copper*, is from the Mine Briccius, near Annaberg. A Chilian *weisskupfererz* contains, according to Plattner (Breith., in Pogg., lviii. 281), 12·9 p. c. of copper, besides iron and sulphur, but no arsenic. Another so called, from Schneeberg, is, according to v. Kobell (J. pr. Ch., lxxi. 159), impure marcasite. *Weisskupfererz* (also called *weisskupfer* and *weisserz*) occurs as the name of a species in all the mineralogical works of last century, from Henckel's Pyrotology, in 1725, where it is called a whitish copper ore, and placed near tetrahedrite; and the light color, from Henckel down, is attributed to the presence of arsenic. It has finally been run out as mostly impure marcasite; and the domeykite and related species (p. 36) are now the only true white copper.

Obs.—The spear variety occurs abundantly in the plastic clay of the brown coal formation at Littwitz and Altsattell, near Carlsbad in Bohemia, and is extensively mined for its sulphur and the manufacture of the sulphate of iron. The radiated variety occurs at the same place; also at Joachimsthal, and in several parts of Saxony. The cockscomb variety occurs with galenite and fluor-spar in Derbyshire; crystals near Castleton in Derbyshire; near Alston Moor in Cumberland; near Tavistock in Devonshire; and radiated at East Wheal Rose and elsewhere in Cornwall.

At Warwick, N. Y., it occurs in simple and compound crystals, in granite, with zircon. Hustis's farm, in Phillipstown, N. Y., affords small crystals, referred by Beck to this species, occurring in magnesian limestone. Massive fibrous varieties abound throughout the mica slate of New England, particularly at Cummington, Mass., where it is associated with cummingtonite and garnet. Occurs at Lane's mine, in Monroe, Conn., and in the topaz and fluor vein in Trumbull; also in gneiss at East Haddam; at Haverhill, N. H., with common pyrite. In Canada in Neebing, a few miles east of the Kamanistiquia R.

Marcasite is employed in the manufacture of sulphur, sulphuric acid, and sulphate of iron, though less frequently than pyrite. Its color is considerably paler than that of ordinary pyrite.

The word *marcasite*, of Arabic or Moorish origin (and variously used by old writers), was the name of common crystallized pyrite among miners and mineralogists in later centuries, until near the close of the last. It was first given to this species by Haidinger in 1845.

The species is probably recognized by Agricola under the name *wasserkies* and *lebererz*; and also under the same by Cronstedt; and it is *Wasserkies* of Hausmann in both editions of his great work. This name, wasserkies (pyrites aquosus, as Cronstedt translates it), is little applicable; yet may have arisen from the greater tendency of the mineral to become moist and alter to vitriol than pyrite—if it be not an early corruption, as Agricola seems to think (see above), of *Weisserkies* (white iron pyrites). It appears to have been used also for easily decomposable pyrite; and *pyrrhotite* was also included under its other name, *pyrites fuscus*. The rhombic crystallization is mentioned by de Lisle; but Hauy long afterward considered it only an irregularity of common iron pyrites. *Marcasite* is made by Breithaupt (J. pr. Ch., iv. 257, 1835) a generic name for the various species of pyrites.

LONCHIDITE *Breit. & Plattn.*, Pogg., lxxvii. 135 (Kausimkies, Br. Char., 254, 1832). This mineral appears to be a mixture of marcasite and mispickel. Breithaupt gives for it the angles 104° 20′ for $I \wedge I$, and 100° 36′ for the brachydome. H.=6·5. G.=4·925—5. Color tin-white, sometimes greenish or grayish; streak black. Analysis by Plattner (loc. cit.), S 49·61, As 4·40, Fe 44·23, Co 0·35, Cu 0·75, Pb 0·20=99·54, equivalent to 24 of marcasite ($Fe\,S^2$) and 1 of $Fe\,As^2$. From Freiberg, Schneeberg, and Cornwall.

Alt.—Limonite and pyrite occur as pseudomorphs after marcasite.

91. LÖLLINGITE. Prismatic Arsenical Pyrites (communic. by Mohs) pt. *Jameson*, iii. 272, 1820. Axotomer Arsenik-Kies pt. *Mohs*, Grundr., 525, 1823. Arsenikalkies, Arsenikeisen, Arseneisen. pt., *Germ.* Leucopyrite pt. *Shep.*, Min., ii. 9, 1835. Arsenosiderit pt. *Glock.*, Grundr., 321, 1839. Mohsine pt. *Chapman*, 1843. Löllingit pt. *Haid.*, Handb., 559, 1845. Sätersbergit *Kenng.*, Min., 111, 1853. Leucopyrite *Dana*, Min., 1868.

Orthorhombic. Form like that of arsenopyrite, and probably the same in angles with that of löllingite. Also massive.

H.=5–5·5. G.=6·8–8·71; 6·80 from Andreasberg, Illing; 7·09, from Fossum, Scheerer; 7·28 from Breitenbrunn, Behncke; 8·67–8·71 from Schladming, Weidenbusch. Lustre metallic. Color between silver-white and steel-gray. Streak grayish-black. Fracture uneven. Brittle.

Comp.—Fe As^2=Arsenic 72·8, iron 27·2=100; or (Fe, Ni, Co) As^2. **Analyses**; 1, 2, Scheerer (Pogg., xlix. 536, l. 153); 3, Weidenbusch (Rose's Kryst. Ch., 54); 4, Behncke (Pogg., xcviii. 187); 5, Illing (ZS. nat. Ver. Halle, 1854, 339):

	As	S	Fe
1. Fossum, Norway	70·09	1·33	27·39=98·81 Scheerer.
2. " "	70·22	1·28	28·14=99·64 Scheerer.
3. Schladming	72·18	0·70	26·48=99·36 Weid.
4. Breitenbrunn	69·85	1·10	27·41, Sb 1·05=99·41 Behncke.
5. Andreasberg	70·59	1·65	28·67=100·91 Illing.

Pyr.—In the closed tube gives a sublimate of metallic arsenic; in the open tube a white sublimate of arsenous acid, with traces of sulphurous fumes. B.B. on charcoal gives the odor of arsenic; in O.F. a white coating of arsenous acid, and in R.F. a magnetic globule. With the fluxes the roasted mineral reacts only for iron.

Obs.—Occurs with copper nickel at Schladming; at Ehrenfriedersdorf, in Saxony; at Sätersberg, near Fossum, in Norway.

A crystal of arsenical iron, weighing two or three ounces, was found in Bedford Co., Penn., but it is not known under what circumstances; and in Randolph Co., N. C., a mass of nearly two pounds weight. Whether these were leucopyrite or lölingite is uncertain. Also found at Paris, Maine.

The name leucopyrite is derived from λευκός, *white*, and *pyrites*; it was given by Shepard in 1835.

92. **RAMMELSBERGITE.** Weissnickelkies *Hoffm.*, Pogg., xxv. 491, 1832. Rammelsbergite *Dana*, Min., 61, 1854. [Not Rammelsbergite (Syn. of Chloanthite) *Haid.*, Handb., 1845.]

Orthorhombic; $I \wedge I$=123°–124°?

H.=5·25–5·75. G.=7·099–7·188 Breith. Slightly ductile. Otherwise like the preceding.

Comp.—Ni As^2, like chloanthite=Arsenic 71·7, nickel 28·3=100. **Analysis**: 1, Hoffmann (l. c.):

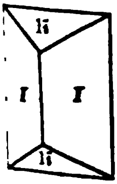
	As	Ni	Bi	Cu	S
Schneeberg	71·30	28·14	2·19	1·50	0·14=102·27

Pyr.—In the closed tube gives a sublimate of metallic arsenic; other reactions the same as with niccolite (p. 60).

Obs.—Occurs at Schneeberg and at Riechelsdorf. It was first separated from the isometric white nickel by Breithaupt.

93. **LEUCOPYRITE.** Syn. same as for LÖLLINGITE (p. 76), with also Glanzarsenikkies *Breith.*, J. pr. Ch., iv. 260, 261, 1835. Mohsine pt. *Chapman*, Pract. Min., 138, 1843. Löllingit pt. *Haid.*, 1845. Geierite (fr. Geyer) *Breith.*, B. H. Ztg., xxv. 167, 1866. Löllingite *Dana*, Min., 1868.

97A



Orthorhombic. Form like that of mispickel, $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}$=122° Rose, 122° 20′ Breith. Cleavage: rather perfect in one direction. Also massive.

H.=5–5·5. G.=6·24–7·3; 6·246 from Geyer; 7·00–7·228 from Reichenstein. In other physical characters like leucopyrite.

Comp.—Fe As+Fe As^2=Arsenic 66·8, iron 33·2=100. **Analyses**: 1, Meyer (Pogg., l. 154); 2, Karsten (Eisenhütt., ii. 19); 3, Weidenbusch (Rose's Kryst. Chem., 54); 4, Behncke (Pogg., xcviii. 187); 5, Hofmann (Pogg., xv. 485):

	As	S	Fe
1. Reichenstein	68·14	1·63	30·24, gangue 3·55=98·56 Meyer.
2. "	65·88	1·77	32·35=100 Karsten.
3. "	65·61	1·09	31·51, gangue 1·04=99·25 Weid.
4. Geyer	58·94	6·07	32·92, Sb 1·37=99·30 B.
5. Reichenstein	65·99	1·94	28·06, gangue 2·17=98·16 Hofmann.

The last analysis affords a composition intermediate between those of leucopyrite and löllingite. The 4th is between this species and mispickel, and has been called *geyerite*. It is tin-white, with black streak. G.=6·321—6·246 Behncke, 6 550 Breith.

Pyr.—Same as for leucopyrite.

Obs.—At Reichenstein in Silesia, in serpentine, with arsenopyrite; at Geyer in Saxony, in crystals, having distinctly the form of arsenopyrite, and massive, mixed with quartz; at Löling, near Huttenberg in Carinthia, in siderite, along with bismuth and scorodite.

Named by Chapman after Mohs, by whom the mineral was first described, and who mentions Löling as the first locality at which it was found; but as *mohsite* was previously given to a variety of menaccanite, Haidinger's name is here adopted.

94. ARSENOPYRITE, or MISPICKEL. ? Lapis subrutilus atque non fere aliter ac argenti spuma splendens et friabilis, *Germ.* Mistpuckel, *Agric.*, Interpr., 465, 1546. Pyrites candidus. Cleavage: *I* rather distinct; *O*, faint traces. Twins: composition-face *I*, and 1-ī. Also columnar, straight, and divergent; granular, or compact

H.=5·5—6. G.=6·0—6·4; 6·269, Franconia, Kenngott. Lustre metallic. Color silver-white, inclining to steel-gray. Streak dark grayish-black. Fracture uneven. Brittle.

Comp., Var.—$FeS^2+FeAs^2=Fe(As,S)^2$=Arsenic 46·0, sulphur 19·6, iron 34·4=100. Part of the iron sometimes replaced by cobalt.

Var. 1. *Ordinary*. Containing little or no cobalt.

Breithaupt makes *I* ∧ *I*=111° 1′ and 1-ī ∧ 1-ī=120° 52′ for cryst. fr. Dalarne, Sweden (his *dalarnite*) and G.=5·66—5·69; 111° 27′ for id. fr. Freiberg, Chemnitz, Munzig, Villarica, Brazil, Riesengebirge, Zinnwald, Altenberg, with G.=5·839—6·053; 112° 4′ and 120° 30′, for id. fr. Thalheim near Stolberg in the Erzgebirge, Schlackenwald, Cornwall, with G.=6·155—6·221 (*giÿlkies* and *thalheimite*, Breith.). For M. of Mt. Sorata, G.=6·255 D. Forbes.

2. *Cobaltic: Danaite*. Containing 4 to 10 p. c. of cobalt, and giving the formula $(Co,Fe)(As,S)^2$. *I* ∧ *I* in cryst. fr. Franconia, N. H., 112° 1′—112°, 1-ī ∧ 1-ī=121° 30′, 1-ĭ ∧ 1-ĭ=100° 15′, Teschemacher; *I* ∧ *I*=112° 33′, 1-ī ∧ 1-ī=121° 20′, 1-ĭ ∧ 1-ĭ=99° 54′, Kenngott. In cryst. from Skutterud, *I* ∧ *I*=111° 40′—112° 2′, 1-ī ∧ 1-ī=121° 30′, Scheerer. *Vermontite* and *akontite* are cobaltiferous (Breith.). The vermontite is supposed to be from Vermont [Franconia?]; it gave him *I* ∧ *I*=111° 38′, and G.=6·207. The akontite is from Hokansbö and Vena, in Sweden, and gave *I* ∧ *I*=110° 29′, with G.=6·008 and 6·059. For D. from Mt. Sorata, fibrous, G.=6·94, granular 5·86, D Forbes. The *danaite* was named after J. Freeman Dana, who first made known the Franconia locality.

3. *Niccoliferous*. Containing nickel.

4. *Argentiferous*. Containing a little silver, and occurring in acicular crystals (Weisserz pt. *Wern.*; Fer arsenical argentifère *H.* From Braünsdorf, in Saxony.

Jordan has analyzed arsenopyrite from near Andreasberg (J. pr. Chem., x. 436) and obtained As 55·000, S 8·344, Fe 36·437, Ag 0·011=99·792, giving nearly the formula $2FeS+3FeAs^2$=Arsenic 56·7, sulphur 8·0, iron 35·2=100. Jordan made out 3 As, S, 3 Fe, which requires arsenic 52·9, sulphur 7·5 iron 39·6=100.

Bentsch obtained from an ore from the coal formation of Merseburg (ZS. Ver. Halle, vii. 372) As 38·23, S 21·70 Fe 35·97, $\ddot{Si}$ 3·27, $\dot{Mg}$, $\dot{Ca}$ *trace*=99·17; G.=5·36—5·66; giving the formula

$2\,Fe\,As^2+3\,Fe\,S^2$. Analysis 11, by Behncke, corresponds to 7 Fe, 6 S, 6 As. The discrepancy in these cases may be owing to impurities.

Pyr., etc.—In the closed tube at first gives a red sublimate of sulphid of arsenic, then a black lustrous sublimate of metallic arsenic. In the open tube gives sulphurous fumes and a white sublimate of arsenous acid. B.B. on charcoal reacts like leucopyrite. The varieties containing cobalt give a blue color with borax-glass when fused in O.F. with successive portions of flux until all the iron is oxydized. Gives fire with steel, emitting an alliaceous odor. Decomposed by nitric acid with separation of arsenous acid and sulphur.

Obs.—Found principally in crystalline rocks, and its usual mineral associates are ores of silver, lead, and tin, pyrite, chalcopyrite, and blende. Occurs also in serpentine.

Abundant at Freiberg and Munzig, where it occurs in veins; at Reichenstein in Silesia, in serpentine; in beds at Breitenbrunn and Raschau, Andreasberg, and Joachimsthal; at Tunaberg in Sweden; at Skutterud in Norway; at Wheal-Mawdlin and Unity, Cornwall, and at other localities; in Devonshire at the Tamar mines.

In *New Hampshire*, in fine crystallizations in gneiss, at Franconia (*danaite*) associated with chalcopyrite; also at Jackson, and at Haverhill. In *Maine*, at Blue Hill, Corinna; Newfield (Bond's mountain), and Thomaston (Owl's head). In *Vermont*, at Brookfield, Waterbury, and Stockbridge. In *Mass.*, at Worcester and Sterling. In *Conn.*, at Chatham, with smaltite and niccolite, at Monroe with wolfram and pyrite; at Derby in an old mine, associated with quartz; at Mine Hill, Roxbury, in fine crystals with siderite. In *New Jersey*, at Franklin. In *N. York*, massive, in Lewis, ten miles south of Keeseville, Essex Co., with hornblende; in crystals and massive, near Edenville, on Hopkins's farm, and elsewhere in Orange Co., with scorodite, iron sinter, and thin scales of gypsum; also in fine crystals at two localities a few rods apart, four or five miles north-west of Carmel, near Brown's serpentine quarry in Kent, Putnam Co. In *California*, Nevada Co., Grass valley, at the Betsey mine, and also at Meadow lake, with gold, the *danaite* in crystals sometimes penetrated by gold. In S. America, in the San Baldomero mine of Mt. Sorata in Bolivia, both the mispickel and danaite, the former having crystallized out of the latter and the most abundant ore: also both at Inquisivi in Bolivia; also, *niccoliferous* var., between La Paz and Yungas in Bolivia (anal. by Krœber).

Alt.—Pseudomorphs consisting of pyrite.

94A. PLINIAN.—Plinian *Breith.*, Pogg., lxix. 430, 1846, B. H. Ztg., xxv. 168, 1866. Var. of Mispickel *G. Rose*, Pogg., lxxvi. 84. Monoclinic, according to Breithaupt, who figures the planes, *P* (1-ĭ), *M* (ĭ-ĭ), *I*, with *h* between *P* and *I*, and *o* below *I*, in the same zone with *P*, *h*, *I*. $I \wedge I=61°\ 30'$, *P* to vertical axis $51°\ 36'=P \wedge M$, $P \wedge h=146°\ 0'$, $M \wedge h=134°\ 20'$, $o \wedge h=115°\ 55'$, $o \wedge ĭ=117°\ 33'$, $o \wedge M=103°\ 15'$, $h \wedge h=119°\ 0'$, *P* on edge $hh=161°\ 12'$, *M* on edge $hh=114°\ 12'$. Cleavage: *P* and *M* distinct. Also massive.

H.=5·5—6. G.=6·272—6·292, fr. St. Gothard; 6·299—6·307. fr. Ehrenfried. Lustre metallic. Color tin-white; streak black.

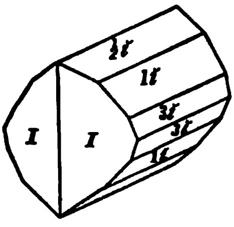
Composition: $Fe\,S^2+Fe\,As^2$, or $Fe\,(S, As)^2$, like arsenopyrite. Analysis by Plattner (Pogg., lxix. 430): As 45·46, S 20·07, Fe 34·46=99·99.

From Ehrenfriedersdorf in crystals, also from St. Gothard, according to Breithaupt.

95. GLAUCODOT. Glaucodot *Breith. & Plattn.*, Pogg., lxvii. 127, 1849.

Orthorhombic. $I \wedge I=112°\ 36'$; form like that of arsenopyrite. Cleavage: basal perfect; prismatic less so. Also massive.

101



H.=5. G.=5·975—6·003. Lustre metallic. Color grayish tin-white. Streak black.

Comp.—$(Co, Fe)\,S^2+(Co, Fe)\,As^2$, with Co to Fe as 2 : 1 (or $(Co, Fe)\,(S, As)^2$)=Sulphur 19·4, arsenic 45·5, cobalt 23·8, iron 11·3=100. Analysis: Plattner (l. c.):

	As	S	Co[a]	Fe	
Chili	43·20	20·21	24·77	11·90	100·08 Plattner.

[a] With trace of nickel.

Pyr.—In the closed tube gives a faint sublimate of arsenous acid. In the open tube sulphurous fumes and a sublimate of arsenous acid. B.B. on charcoal in R.F. gives off sulphur and arsenic, fusing to a feebly magnetic globule, which is black on the surface, but on the fracture has a light bronze color and a metallic lustre. Treated with borax in R.F. until the globule has a bright metallic surface, the flux shows a strong reaction for iron; if the remaining globule is treated with a fresh portion of borax in O.F., the flux becomes colored smalt-blue from oxydized cobalt.

Obs.—Occurs in chlorite slate with cobaltite, in the province of Huasco, Chili. The supposed glaucodot of Orawicza is *alloclasite* (p. 81.)

96. PACITE. Rhombites Pacites, Pazit (fr. La Paz), *Breith.*, B. H. Ztg., xxv. 167, 1866.

Orthorhombic. $I \wedge I = 115° 24'$. $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, over O, 119° 56′. Occurring planes O, I, $1\text{-}\bar{i}$. Measurements only approximative. Cleavage: I rather indistinct. Also massive.

H.=4–4·5. G.=6·297–6·303, Weisbach. Lustre metallic. Color tin-white, inclining to steel-gray; streak black.

Comp.—$Fe\,S^2 + 4\,Fe\,As^2$=Arsenic 63·56, sulphur 6·78, iron 29·66=100. Analysis by Winkler (l. c.):

As 64·84 S 7·01 Fe 24·35 Co 0·13 Cu 0·11 Bi 0·10 Au, Ag 0·006 gangue 2·88=99·426.

Obs.—From La Paz in Bolivia, in masses and thin plates in the gangue, with native gold and bismuth.

Named from the locality, or its Latin signification, *pax*, *peace*.

97. ALLOCLASITE. Alloklas *Tschermak*, Ber. Ak. Wien, liii. 220, 1866, Glaucodot pt. *Breith.*

Orthorhombic. $I \wedge I = 106°$; $O \wedge 1\text{-}\bar{i} = 118°$; $1\text{-}\bar{i} \wedge 1\text{-}\bar{i} = 58°$. Cleavage: O and I perfect.

H.=4·5. G.=6·6. Color steel-gray. Streak nearly black.

Comp.—$2\,Co\,S^2 + Co\,As^2 + 4\,Bi\,As$, or a compound related to glaucodot and cobaltite+4 Bi As; or $3\,Co\,S + 3\,Co\,As + 2\,As\,S^3$, Tschermak.

Analyses: 1, Hein (l. c.); 2, 3, Hubert & Patera (Jahrb. Min., 1848, 325):

	S	As	Bi	Au	Fe	Zn	Co	Ni
1. Orawicza	16·22	32·69	30·15	0·68	5·58	2·41	10·17	1·55=99·45 Hein.

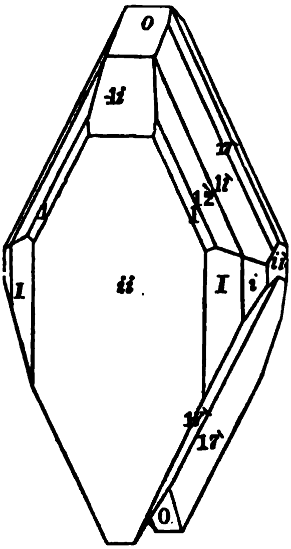
102



Cleavage: *i-i* distinct. Twins: composition face *i-i*, as in the figure. Also massive; imperfectly columnar to granular.

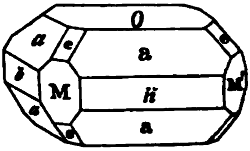
H.=1·5–2 G.=7·9–8·33; 8·28, Petz. Lustre metallic. Streak and color pure steel-gray to silver-white, and sometimes nearly brass-yellow. Fracture uneven.

Comp., Var.—(Ag, Au) Te^2= (if Ag : Au=1 : 1) Tellurium 55·8, gold 28·5, silver 15·7=100. Antimony sometimes replaces part of the tellurium, and lead part of the other metals.

Var. 1. *Sylvanite.* (Schrifterz *Wern.*, etc., 1st par. Syn.) Containing little or no lead. G.=7·5—8·5. Anal. 1–7. The angles given above are of this variety, and are from Kokscharof.

2. *Müllerite.* Gelberz *Karsten*, Weisstellur *Wern.*, etc., 2d par. Syn.) Containing much lead. Anal. 8–10. Haidinger gives the annexed figure and angles for the *weisstellur*, making it different in dimensions from the preceding. M ∧ M=105° 30′, O ∧ a=108° 30′, O ∧ *a*=143° 5′. It is from Nagyag. G.=7·99–8·33. The yellow color does not distinguish the two varieties, and the propriety of separating them is doubtful. Much of the so-called *gelberz* (yellow ore) is not mullerite, as shown by Petz's analyses.

103.



Analyses: 1, Klaproth (Beitr., iii. 16); 2, Berzelius (Jahresb., xiii. 162, analysis imperfect); 3–9, Petz (Pogg., lvii. 472); 10, Klaproth (Beitr., iii. 20):

		Te	Sb	Au	Ag	Pb
1. Offenbanya		60·	——	30·	10·	——=100 Klaproth.
2. "		52·	*tr.*	24·0	11·3	1·5, Cu, Fe, S, As *tr.* B.

10. Müllerite, *Gelberz*		44·75	——	26·75	8·50	19·50, S 0·5=100 K.

Pyr., etc.—In the open tube gives a white sublimate, which near the assay is gray; when treated with the blowpipe flame the sublimate fuses to clear transparent drops. B.B. on charcoal fuses to a dark-gray globule, covering the coal with a white coating, which treated in R.F. disappears, giving a bluish-green color to the flame; after long blowing a yellow, malleable metallic globule is obtained. Most varieties give a faint coating of oxyd of lead and antimony on charcoal.

Obs.—With gold, at Offenbanya in Transylvania, in narrow veins, which traverse porphyry; also at Nagyag in the same country. In California, Calaveras Co., at the Melones and Stanislaus mines.

Named from Transylvania, the country in which it occurs, and in allusion to *sylvanium*, one of the names at first proposed for the metal tellurium. Called *graphic* because of a resemblance in the arrangement of the crystals to writing characters.

For Kokscharof's paper on cryst., see Bull. Ac. St. Pet., ix. 192. His *b*, *c*, *a* are *c*, *a*, *m* of Brooke and Miller.

99. NAGYAGITE. Aurum Galena, Ferro, et particulis volatilibus mineralisatum, *Scopoli*, Ann. Hist. Nat., iii. 107; *v. Born*, Lithoph., i. 68, 1772. Nagiakererz *Wern.* Bergm. J., 1789. Tetragonal. *O* ∧ 1-*i*=127° 37′; *a*=1·298. Observed planes as in the annexed figure. *O* ∧ 1=118° 37′, 1 ∧ 1=103° 14′, *O* ∧ 2-*i*=111° 4′, 2-*i* ∧ 2-*i*, bas.,=137° 52′. Cleavage: basal. Also granularly massive, particles of various sizes; generally foliated.

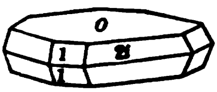
104



H.=1–1·5. G.=6·85–7·2. Lustre metallic, splendent. Streak and color blackish lead-gray. Opaque. Sectile. Flexible in thin laminæ.

Comp.—Analyses: 1, Klaproth (Beitr., iii. 32); 2, Brandes (Schw. J., xxxv. 409); 3, P. Schönlein (J. pr. Ch., lx. 166); 4, 5, Folbert (Verh. Sieb. Ver. Nat. Hermannstadt, viii. 99, and Kenng. Ueb., 1856); 6, S. J. Kappel (Jahresb., 1859, 770):

	Te	S	Pb	Au	Ag	Cu
1.	32·2	3·0	54·0	9·0	0·5	1·3=100 Klaproth.
2.	31·96	3·07	55·49	8·44	*tr.*	1·14=100·10 Brandes.
3.	30·52	8·07	50·78	9·11	0·53	0·99=100 Schönlein.
4.	17·22	9·76	60·83	5·84	——	—— Sb 3·69, Se *tr.*=97·34 Folbert.
5.	18·04	9·68	60·27	5·98	——	—— Sb 3·86, Se *tr.*=97·83 Folbert.
6.	15·11	8·56	60·10	12·75	1·82	—— Se 1·66=100 Kappel.

Schönlein found in other trials, Pb 51·01, 51·06, Te 26·67, S 9·62, 10·59; and Petz obtained (Pogg., lvii. 478), 8·54, 7·81, 6·48 per cent. of gold. Schönlein's and Folbert's analyses (3–5) correspond to 2 (Pb, Au)+3 (Te, Sb, S) Ramm. In Schönlein's, Te : S=1 : 3 nearly; in Folbert's Te+Sb : S=1 : 2. The formula for the latter may be written $\text{R Te} + \text{R S}^2$.

Pyr., etc.—In the open tube gives, near the assay, a grayish sublimate of antimonate and tellurate, with perhaps some sulphate of lead; farther up the tube the sublimate consists of antimonous acid, which volatilizes when treated with the flame, and tellurous acid, which at a high temperature fuses into colorless drops. B.B. on charcoal forms two coatings: one white and volatile, consisting of a mixture of antimonite, tellurite, and sulphate of lead; and the other yellow, less volatile, of oxyd of lead quite near the assay. If the mineral is treated for some time in O.F. a malleable globule of gold remains; this cupelled with a little assay lead assumes a pure gold color. Decomposed by nitro-muriatic acid.

Obs.—At Nagyag and Offenbanya in Transylvania, in foliated masses and crystalline plates, accompanying, at the former place, rhodonite, blende, and gold; and at the latter, associated with antimonial ores. Folbert states that the Nagyag crystals examined by him were hexagonal and not of the tetragonal system, and had G.=6·680, or not exceeding this.

Berthier has analyzed another ore very similar to the above in physical characters, consisting of Tellurium 13·0, sulphur 11·7, lead 63·1, gold 6·7, antimony 4·5, copper 1·0=100; corresponding to 21S, 6Te, 4Sb, 18Pb, 2Au, but probably impure with sulphuret of antimony. It is called *Blatterine* by Huot, Min., i. 189, 1841.

(A) SILBERPHYLLINGLANZ *Breith.* (Schw. J., i. 178, 1828), occurring in gneiss at Deutsch-Pilsen, Hungary, appears to be related to nagyagite. Its color is blackish-gray; structure foliated massive, it having one perfect cleavage; H.=1·2; G.=5·8—5·9.

According to Plattner (Probirkunst, 3d edit., 421) the constituents are antimony, lead, tellurium, gold, silver, and sulphur—4·9 p. c. of gold, 0·3 of silver—the sulphur probably in combination with the antimony and lead. Only a trace of selenium was found, contrary to the earlier determinations of Harkort and Breithaupt.

100. COVELLITE. *Freiesleben*, Geogn. Arb., iii. 129 (fr. Sangerhausen); Kupferindig *Breith.*, in Hoffm. Min., iv. 2, 178, 1817. Indigo-Copper; Blue Copper. Covelline, Sulfure de cuivre du Vesuve, *Beud.*, ii. 409, 1832. Breithauptite *Chapm.*, Min., 125, 1843. Cantonite *Pratt*, Am. J. Sci., II. xxii. 449, xxiii. 409.

Hexagonal. Observed planes: *O*, *I*; with faces of two hexagonal pyramids 1 and ¼; basal edge of 1,155° 24′; 1 ∧ ¼=150° 24′ Kenngott. Cleavage: basal, very perfect. Rarely in crystals. Commonly massive or spheroidal; surface, sometimes crystalline.

H.=1·5–2. G. of crystals=4·590, 4·636, Zepharovich. Lustre of crystals submetallic, inclining to resinous, a little pearly on cleavage-face; subresinous or dull when massive. Color indigo-blue or darker. Streak lead-gray to black, shining. Opaque. Thin leaves, flexible.

Comp.—Ꞓu S^2=Cu S=Sulphur 33·5, copper 66·5=100. Analyses: 1, Walchner (Schw. J., xlix. 158); 2, Covelli (Ann. Ch. Phys., xxxv. 105); 3, C. v. Hauer (Ber. Ak. Wien, xii. 22):

	S	Cu	Fe
1. Badenweiler	32·64	64·773	0·462, Pb 1·046=98·921 Walchner.
2. Vesuvius	32·0	66·0	——=98·0 Covelli.
3. Leogang	34·30	64·56	1·14=100 Hauer.

A Dillenberg covellite afforded Grimm (Jahresb., 1850, 702) 66·82 bisulphid of copper, 3·96 pyrite, 18·63 quartz, and 10·57 F̈e M̈n Ḣ.

Analysis of ore of Algodon bay, Bolivia, by v. Bibra, in J. pr. Ch., xcvi. 202.

Pyr.—In the closed tube gives a sublimate of sulphur; in the open tube sulphurous fumes. B.B. on charcoal burns with a blue flame, emitting the odor of sulphur, and fuses to a globule, which reacts like chalcocite.

Obs.—With other copper ores near Badenweiler at Leogang in Salzburg, where it is sometimes in small crystals of the form above described; at Kielce in Poland· Sangerhausen in province of Saxony, Prussia; Mansfeld, Thuringia; Vesuvius, on lava; common in Chili; at Algodon bay in Bolivia.

Named after Covelli, the discoverer of the Vesuvian covellite, by Beudant, and without reference to the ore as previously described.

Covellite is a result of the alteration of other ores of copper, and is often mixed with chalcocite or copper-glance, from which it has been derived. (See *Digenite* and *Carmenite*, p. 53.)

(A) CANTONITE is covellite from the Canton mine, Georgia, occurring in cubes, with a cubical cleavage. It is associated with *harrisite* (pseudomorphs of chalcocite after galenite, see p. 53), and is regarded by Genth as a pseudomorph of covellite after the harrisite. Genth obtained in his analysis (l. c., xxiii. 417), S 32·76, Se *trace*, Ag 0·36, Cu 65·60, Pb 0·11, Fe 0·25, insoluble 0·16 =99·24.

(B) ALISONITE *Field.*—Alisonite is an indigo-copper, containing a much larger proportion of lead than the cantonite; but it is probably, like that, a result of the alteration of galenite. The color is a deep indigo-blue, tarnishing on exposure; G.=6·10; H.=2·5—3. Analyses by F Field (1, Am. J. Sci., II. xxvii. 387; and 2, J. Ch. Soc., xiv. 160):

	S	Cu	Pb
1.	17·00	53·63	28·25=98·88
2.	17·69	53·28	28·81=99·78

Corresponding to 3 Ꞓu S+Pb S=S 17·78, Cu 53·34, Pb 28·88. It occurs at "Mina Grande" near Coquimbo, Chili, associated with cerussite, malachite, and vanadate of lead and copper.

3. SULPHARSENITES, SULPHANTIMONITES, SULPHO-BISMUTHITES.*

The species here included are arranged according to the amount of the basic metal (lead, silver, copper, iron), beginning with those in which the proportion is the smallest. Several of the species require more investigation:

101. CHALCOSTIBITE. Kupferantimonglanz *Zinken*, Pogg., xxxv. 357, 1835. Sulphuret of Copper and Antimony; Antimonial Copper. Rosite *Huot*, Min. i. 197, 1841. Chalkostibit *Glock.*, Syn., 32, 1847. Wolfsbergite *Nicol*, Min., 484, 1849.

Orthorhombic. $I \wedge I = 101°$, i-$\bar{2} \wedge i$-$\bar{2} = 138° 12'$, i-$\bar{2} \wedge i$-$\bar{i} = 112° 24'$. In small aggregated tabular prisms presenting the planes O, I, i-$\bar{2}$, i-$\bar{i}$. Cleavage: i-$\bar{i}$, very perfect; O, less so.

H.=3–4. G.=4·748, H. Rose; 5·015, Breith. Lustre metallic. Streak black. Color between lead-gray and iron-gray. Opaque. Fracture conchoidal.

Comp.—Ɵu S + $Sb^2 S^3$=Sulphur 25·7, antimony 48·9, copper 25·4=100. Analyses: 1, H. Rose (l. c.); 2, T. Richter (B. H. Ztg., 1857, No. 27):

	S	Sb	Cu	Fe	Pb
1. Wolfsberg	26·34	46·81	24·46	1·39	0·56=99·56 Rose.
2. Guadix	25·29	48·30	25·36	1·23	——=100·18 Richter.

The iron is supposed to exist as pyrite, and the lead as feather ore.

Pyr., etc.—In the closed tube decrepitates at first, and then fuses, giving a faint sublimate of sulphid of antimony, which on cooling is dark red; in the open tube gives sulphurous and antimonous fumes, the latter forming a white sublimate. B.B. on charcoal fuses to a globule, emitting antimonous fumes, coating the coal white; the globule treated with borax reacts for iron; with soda gives a globule of metallic copper.

Decomposed by nitric acid, with separation of sulphur and oxyd of antimony.

Obs.—From Wolfsberg in the Harz, in nests imbedded in quartz; and at Guadix, Spain. It is usually covered with a coating of pyrite. Glocker's name antedates Nicoll's. *Rosite* has an earlier use.

102. EMPLECTITE. Wismuth-Kupfererz (fr. Tannenbaum) *Selb*, Tasch. Min., xi. 441, 451 1817. Kupferwismuthglanz *R. Schneider*, Pogg., xc. 166, 1853. Emplektit *Kenng.*, Min. Forsch., 125, 1853. Tannenite *Dana*, Min., 73, 1854. Hemichalcit *v. Kob.*, Gesch. Min., 600, 1864.

Orthorhombic. *I* ∧ *I*=92° 20′, *O* ∧ 1-ī=141° 8′. In thin striated flattened prisms. Observed planes, *I*, *i*-ī, *i*-$\frac{3}{2}$, *i*-$\frac{5}{3}$, *i*-2̆, *i*-7̆, 1-ī, $\frac{1}{2}$-ī. *i*-ī ∧ 1-ī =128° 52′, *i*-ī ∧ $\frac{1}{2}$-ī=104° 55′, *i*-ī ∧ *i*-$\frac{3}{2}$=147° 23′, *i*-ī ∧ *i*-2̆=117° 30′, *i*-$\frac{3}{2}$ ∧ *i*-$\frac{3}{2}$=114° 46′, *i*-2̆ ∧ *i*-2̆, ov. *i*-ī=55°, 1-ī ∧ 1-ī, top,=102° 16′.
Lustre bright metallic. Color grayish to tin-white.

Comp.—$\bar{C}u\,S + Bi^2\,S^3$=Sulphur 19·1, bismuth 62·0, copper 18·9=100. Analyses: R. Schneider (Pogg., xc. 166):

($\frac{2}{3}$) Sulphur 18·83	Bismuth 62·16	Copper 18·72=99·71	
" 22·4	" 52·7	" 20·6	Iron 4·1=99·8

Pyr., etc.—In the open tube gives sulphurous fumes. B.B. on charcoal fuses easily, with frothing and spirting; treated with soda coats the coal dark-yellow from oxyd of bismuth, and gives a globule of copper.

Decomposed by nitric acid, with separation of sulphur.

Obs.—From the mines of Tannenbaum, near Schwarzenberg, Saxony; also from Cerro Blanco in Copiapo, Chili (Ann. d. M., IV. v. 459).

On cryst., see Dauber, Pogg., xcii. 241; Weisbach, Pogg., cxxviii. 435.

103. CHIVIATITE. Chiviatit *Ramm.*, Pogg., lxxxviii. 320.

Foliated massive; cleavable in three directions in one zone, one making an angle with the second of 153°, and with the third of 133°, Miller.
G.=6·920. Lustre metallic. Color lead-gray,

Comp.—$(\bar{C}u, Pb)\,S + \frac{2}{3}\,Bi^2\,S^3$=Sulphur 17·76, bismuth 62·96, lead 16·72, copper 2·56=100 Analysis by Rammelsberg (l. c.):

S	Bi	Pb	Cu	Fe	Ag	insol.
18·00	60·95	16·73	2·42	1·02	*tr.*	0·59=99·71

Pyr.—Same as for aikinite, Ramm.

Obs.—From Chiviato, in Peru; along with pyrite and barite. Resembles bismuth-glance.

104. BERTHIERITE. Haidingerite *Berthier*, Ann. Ch. Phys., xxxv. 351, 1827. Berthierit *Haid.*, Ed. J. Sci., vii. 353, 1827.

In elongated prisms or massive; a longitudinal cleavage rather indistinct. Also fibrous massive, plumose; also granular.
H.=2—3. G.=4—4·3. Lustre metallic, less splendent than stibnite. Color dark steel-gray, inclining to pinchbeck-brown; surface often covered with iridescent spots.

Comp.—$Fe\,S + Sb^2\,S^3$=Sulphur 29·9, antimony 57·0, iron 13·1=100. Analyses: 1, 2, 3, Berthier (Ann. Ch. Phys., xxxv. 51); 4, Rammelsberg (Pogg., xl. 153); 5, Pettko (Haid. Ber., i 32); 6, v. Hauer (Jahrb. G. Reichs., iv. 635); 7, Sackur (Ramm., Min. Chem., 988); 8, Ramm. (ZS G., xviii. 244):

	S	Sb	Fe	Zn

5. Arany Idka	29·27	57·88	12·85	——=100 Pettko. G.=4·043.
6. Bräunsdorf	30·53	59·31	10·16	——=100·73 Hauer.
7. "	28·77	56·91	10·55	—— Mn 3·73=99·96 Sackur.
8. S. Antonio, Cal.	29·12	56·61	10·09	—— Mn 3·56=99·38 Ramm.

Anal. 3–8 correspond to the above formula.

No. 1=$3FeS+2Sb^2S^3$=Sulphur 30·5, antimony 51·7, iron 17·8=100.
No. 2=$3FeS+4Sb^2S^3$=Sulphur 29·6, antimony 60·0, iron 10·4=100.

Pyr., etc.—In the closed tube fuses, and gives a faint sublimate of sulphur; with a strong heat yields a black sublimate of sulphid of antimony, which on cooling becomes brownish-red. In the open tube gives off fumes of sulphur and antimony, reacting like stibnite. B.B. on charcoal gives off sulphur and antimony fumes, coats the coal white, and the antimony is expelled, leaving a black magnetic slag, which with the fluxes reacts for iron.

Dissolves readily in muriatic acid, giving out sulphuretted hydrogen.

Obs.—At Chazelles and Martouret in Auvergne, associated with quartz, calcite, and pyrite; in the Vosges, Commune of Lalaye, containing about 32 of Sb to 18 of Fe; at Anglar in La Creuse; also at Bräunsdorf in Saxony, and at Padstow in Cornwall; at Arany Idka in Hungary; at Real San Antonio, Lower California, massive; near Fredericton, N. Brunswick.

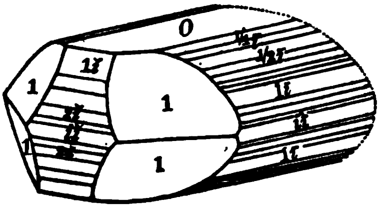
Yields antimony, but of inferior quality.

105. SARTORITE. Skleroklas + Arsenomelan *v. Waltershausen*, Pogg., xciv. 115, 1855, c. 537. Skleroklas *v. Rath*, ib., cxxii. 380. Binnit *C. Heusser*, Pogg. xciv. 335, 1855, xcvii. 120. Dufrenoysite, pt., *Duf.*, Tr., pl. 235, f. 66. *Descl.*, Ann. d. M., V. viii. 389, 1855. Arsenomelan *Petersen*, Offenb. Ver., vii. 13, 1866. Sartorite *Dana*.

Orthorhombic. $I \wedge I$=123° 21′, $O \wedge 1\text{-}\bar{i}$=131° 3′; $a:b:c$=1·1483 : 1 : 1·8553. Observed planes: O (broad); in zone $i\text{-}\bar{i}$ (all narrow, the crystals elongated and channelled in this direction) $\frac{1}{8}\text{-}\bar{i}$, $\frac{1}{4}\text{-}\bar{i}$, $\frac{5}{14}\text{-}\bar{i}$, $\frac{5}{11}\text{-}\bar{i}$, ? $\frac{1}{2}\text{-}\bar{i}$, $\frac{5}{8}\text{-}\bar{i}$, $\frac{6}{7}\text{-}\bar{i}$, $\frac{8}{9}\text{-}\bar{i}$, $1\text{-}\bar{i}$, $\frac{5}{4}\text{-}\bar{i}$, $\frac{4}{3}\text{-}\bar{i}$, ? $5\text{-}\bar{i}$, $10\text{-}\bar{i}$, $i\text{-}\bar{i}$; in zone $i\text{-}\breve{i}$, $1\text{-}\breve{i}$, $^4\text{-}\breve{i}$, $\frac{3}{2}\text{-}\breve{i}$, $2\text{-}\breve{i}$, $4\text{-}\breve{i}$, $i\text{-}\breve{i}$; 1 (large planes), v. Rath.

$O \wedge 1$=127° 28½′, calc.
$O \wedge 1$=126 40, meas.
$O \wedge 1\text{-}\bar{i}$=130 15, meas.
$O \wedge 2\text{-}\bar{i}$=128 56.
$1 \wedge 1$, brach.,=91 22
$1 \wedge 1$, macrod.,=135 46
$1 \wedge 1$, bas.,=105 3
$1 \wedge 1\text{-}\breve{i}$=135 41
$1 \wedge 1\text{-}\bar{i}$=157 53

105



Crystals slender. Cleavage: O quite distinct.

H.=3. G.=5·393. Lustre metallic. Color dark lead-gray; streak reddish-brown. Opaque. Brittle.

Comp.—$PbS+As^2S^3$=Sulphur 26·39, arsenic 30·93, lead 42·68=100. Analyses: 1, Waltershausen (Pogg., xcvii. 124); 2, 3, Stockar-Escher (Kenng. Ueb., 56–57, 176):

	S	As	Pb	Ag	Fe
1. Binnen	25·91	28·56	44·56	0·42	0·45=99·90 Walt.
2.	25·30	26·33	46·83	1·62	——=100·08 S.-E.
3. "	25·77	26·82	47·39	—	——=99·98 S.-E.

Von Waltershausen states that his analysis (No. 1) was made on striated crystals, which proves it to pertain to this species as defined by v. Rath (l. c.). The other two analyses by Stockar-

Escher may have been made on material containing portions of the other prismatic species of the locality; yet in the sulphur and arsenic they agree with the other analysis, and diverge but little in the lead.

Pyr., etc.—Nearly the same as for dufrenoysite, but differing in strong decrepitation.

Obs.—From the Binnin valley with dufrenoysite and binnite. As the name Scleroclase is inapplicable, and the mineral was first announced by Sartorius v. Waltershausen, the species may be appropriately called *Sartorite*.

106. ZINKENITE. Zinkenit *G. Rose*, Pogg., vii. 91, 1826.

Orthorhombic. $I \wedge I = 120° 39'$, Rose; 120° 34′, Kenngott. Usual in twins, as hexagonal prisms, with a low hexagonal pyramid at summit; angle at pyramidal edge=165° 26′; I on face of pyramid=104° 42′. Lateral faces longitudinally striated. Sometimes columnar, fibrous, or massive. Cleavage not distinct.

H.=3–3·5. G.=5·30–5·35. Lustre metallic. Color and streak steel-gray. Opaque. Fracture slightly uneven.

Comp.—$PbS + Sb^2S^3$=Sulphur 22·1, antimony 42·6, lead 35·3=100. Analyses: 1, 2, H. Rose Pogg., viii. 99); 3, Kerl (B. H. Ztg., 1853, No. 2):

1.	Wolfsberg	S 22·58	Sb 44·39	Pb 31·84	Cu 0·42=99·23 Rose.
2.	"	*undet.*	44·11	31·97	*undet.* Rose.
3.	"	21·22	43·98	30·84	Ag 0·12, Fe 1·45=97·61 K.

Pyr., etc.—Decrepitates and fuses very easily; in the closed tube gives a faint sublimate of sulphur, and sulphid of antimony; in the open tube sulphurous fumes and a white sublimate of oxyd of antimony. B.B. on charcoal is almost entirely volatilized, giving a coating which on the outer edge is white, and near the assay dark yellow; with soda in R.F. yields globules of lead.

Soluble in hot muriatic acid with evolution of sulphuretted hydrogen and separation of chlorid of lead on cooling.

Obs.—Occurs in the antimony mine of Wolfsberg in the Harz; the groups of columnar crystals occur on a massive variety in quartz; the crystals sometimes over half an inch long, and two or three lines broad, frequently extremely thin and forming fibrous masses. Has been reported from St. Trudpert in the Schwarzwald. Named in honor of Mr. Zinken, the director of the Anhalt mines, by G. Rose.

Resembles stibnite and bournonite, but may be distinguished by its superior hardness and specific gravity.

Kenngott makes the crystallization monoclinic, and the pyramidal planes oblique basal planes; but such twins with pyramids so formed are not known among monoclinic species.

107. JORDANITE. Jordanit *v. Rath*, Verh. Nat. Ver. Bonn, March, 1864, Pogg., cxxii. 387, 1864.

Orthorhombic. $I \wedge I = 123° 29'$; $O \wedge 1\text{-}\bar{i} = 128° 27'$; $a : b : c = 1·2595 : 1 : 1·8604$. Observed planes: O; in zone $i\text{-}\breve{i}$, $\frac{1}{4}\text{-}\breve{i}$, $\frac{4}{7}\text{-}\breve{i}$, $\frac{6}{5}\text{-}\breve{i}$, $\frac{3}{2}\text{-}\breve{i}$, $\frac{12}{7}\text{-}\breve{i}$, $2\text{-}\breve{i}$, $3\text{-}\breve{i}$, $6\text{-}\breve{i}$; in zone 1, $\frac{1}{5}$, $\frac{2}{7}$, $\frac{1}{3}$, $\frac{2}{5}$, $\frac{1}{2}$, $\frac{4}{7}$, 1, $\frac{3}{2}$, I. Planes all narrow, except O; crystals hexagonal in general form.

$O \wedge 2\text{-}\breve{i} = 126° 27'$ $O \wedge \frac{12}{7}\text{-}\breve{i} = 130° 45'$ $O \wedge \frac{3}{2} = 115° 0'$

$O \wedge \frac{3}{2}\text{-}\breve{i} = 134\ 34$ $O \wedge 1\text{-}\breve{i} = 124\ 58$ $O \wedge \frac{1}{2} = 144\ 26\frac{1}{2}$

Twins: composition-face I; forms hexagonal, arragonite-like. Cleavage: $i\text{-}\breve{i}$ distinct. Streak pure black.

Comp.—Undetermined.

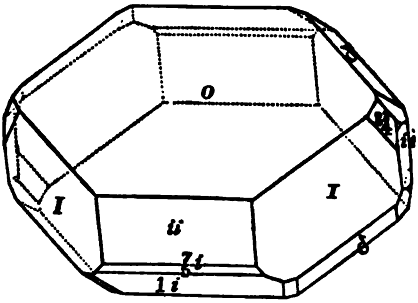
Pyr., etc.—Nearly as for sartorite.

Obs.—From the Binnen valley, with sartorite (q. v.). Approaches closely sartorite in its planes and angles, but differs in occurring in twin crystals, and in its black streak.

Named after Dr. Jordan of Saarbruck, who furnished vom Rath with his specimens.

108. MIARGYRITE. Hemiprismatische Rubin-Blende (fr. Bräunsdorf) *Mohs*, Grundr., 606, 1824. Miargyrit *H. Rose*, Pogg., xv. 469, 1829. Hypargyrite, Hypargyron-Blende (fr. Clausthal), *Breith.*, Char., 286, 333, 1832. Kenngottite (fr. Felsobanya) *Haid.*, Ber. Ak. Wien, xxii. 236 1856.

Monoclinic. $C = 48° 14'$, $I \wedge I = 106° 31'$, $O \wedge 1\text{-}\grave{i} = 136° 8'$; $a : b : c = 1·2883 : 1 : 0·9991$, Naumann. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}\grave{i}$, $i\text{-}2$



106

i-$\frac{4}{3}$; domes $\frac{1}{8}$-i, $\frac{1}{4}$-i, $\frac{3}{4}$-i, 1-i, $\frac{1}{6}$-i, 1-i, 3-i; octahedral, $\frac{3}{4}$; $\frac{1}{16}$-5, $\frac{1}{6}$-$\frac{1}{4}$, $\frac{2}{11}$-$\frac{4}{3}$, $\frac{1}{6}$-$\frac{4}{3}$; $\frac{17}{4}$-$\frac{4}{3}$, 4-$\frac{4}{3}$, 1-$\frac{4}{3}$, 3-$\frac{4}{3}$, $\frac{3}{2}$-3, 9-$\frac{4}{3}$.

$O\wedge i\text{-}i=131°\ 46'$ $O\wedge \frac{1}{4}\text{-}i=139°\ 58'$
$O\wedge I=122\ \ 16$ $O\wedge 1\text{-}i=\ 98\ \ 24$
$O\wedge \frac{3}{4}=109\ \ 16$ $i\text{-}i\wedge 1\text{-}i=129\ \ 50$

Observed angles by Weisbach, from Braünsdorf crystals: $I\wedge I=104°\ 36'-105°\ 50'$; $O\wedge i\text{-}i=132°\ 28', 134°\ 15', 127°\ 11', 131°\ 35'$; $i\text{-}i\wedge 1\text{-}i=129°\ 17', 129°, 49'$.

Crystals thick tabular, or stout, or short prismatic, pyramidal. Lateral planes deeply striated. Cleavage: $\frac{1}{4}$-i, 1-i imperfect.

H.=2—2·5. G.=5·2—5·4; mostly 5·22—5·24. Lustre submetallic-adamantine. Color iron-black. Streak dark cherry-red. Opaque, except in thin splinters, which, by transmitted light, are deep blood-red. Fracture subconchoidal.

Comp.—$\mathrm{Ag\,S+Sb^2S^3}$=Sulphur 21·8, antimony 41·5, silver 36·7=100. Analysis by H. Rose (Pogg., xv. 469):

S 21·95 Sb 39.14 Ag 36·40 Cu 1·06 Fe 0·62=99·17.

The *kenngottite* (l. c.) which Weisbach refers here (Pogg., cxxv. 457), has not been analyzed; von Hauer found in it (Pogg., xcviii. 165) about 30 p. c. of silver; G.=6·06. *Hypargyrite* is a massive variety; G.=4·779—4·890, Breith.; it afforded Plattner (l. c.) 35 p. c. of silver. For Weisbach's measurements see Pogg., l. c.

Pyr., etc.—In the closed tube decrepitates, fuses easily, and gives a sublimate of sulphid of antimony; in the open tube sulphurous and antimonous fumes, the latter as a white sublimate. B.B. on charcoal fuses quietly with emission of sulphur and antimony fumes to a gray bead, which after continued treatment in O.F. leaves a bright globule of silver. If the silver globule be treated with phosphorus salt in O.F., the green glass thus obtained shows traces of copper when fused with tin in R.F.

Decomposed by nitric acid, with separation of sulphur and oxyd of antimony.

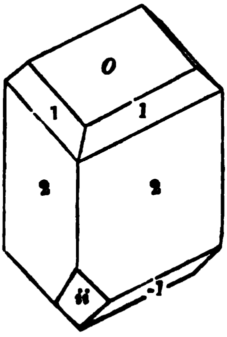
Obs.—At Braünsdorf, near Freiberg in Saxony, associated with tetrahedrite, pyrargyrite, valentinite, etc.; Felsobanya (*kenngottite*) with pyrite, galenite, blende, barite; Przibram in Bohemia; Clausthal (*hypargyrite*); Guadalajara in Spain; at Parenos, and the mine Sta. M. de Catorce, near Potosi; also at Molinares, Mexico, with diallogite.

Named from μεῖον, *less*, ἄργυρος, *silver*, because it contains less silver than some kindred ores.

109. PLAGIONITE. Plagionit *G. Rose*, Pogg., xxviii. 421, 1833.

Monoclinic. $C=72°\ 28'$, $I\wedge I=85°\ 25'$, $O\wedge 1\text{-}i=158°\ 9'$, Rose; $a:b:c=0{\cdot}37015:1:0{\cdot}8802$. Observed planes as in f. 107.

107



$O\wedge 1=154°\ 20'$ $O\wedge i\text{-}i=107°\ 32'$
$O\wedge 2=138\ \ 52$ $1\wedge 1=142\ \ 3$
$O\wedge -1=149$ $2\wedge 2=120\ \ 49$

Crystals thick tabular; the plane O shining and smooth; others striated. Cleavage: 2, perfect, but seldom affording smooth surfaces. Also massive, granular.

H.=2·5. G.=5·4. Lustre metallic. Color blackish lead-gray. Opaque. Brittle.

Comp.—$Pb\,S + Sb^2S^3 + \frac{1}{2}\,Pb\,S$=Sulphur 21·3, antimony 38·2, lead 40·5. **Analyses:** 1, H. Rose (Pogg., xxviii. 428); 2, Kudernatsch (Pogg., xxxvii. 588); 3, Schultz (Ramm. Min. Ch., 1006):

1.	Wolfsberg	S 21·53	Sb 37·94	Pb 40·52=99·99 Rose.
2	"	21·49	37·53	40·98=100 Kudernatsch.
3	"	21·10	37·84	39·36, Cu 1·27=99·53 Schultz.

Pyr.—Same as in zinkenite.

Obs.—At Wolfsberg in geodes and druses of crystals in massive plagionite, or crystallized on quartz, and was discovered by Zincken. Named, in allusion to its unusually oblique crystallization, from πλάγιος, *oblique*.

Taking the planes 2, 2, as the lateral faces of the fundamental prism, the lateral angle is nearly the same as in freieslebenite.

110. BINNITE. Dufrenoysite *v. Waltershausen*, Pogg., xciv. 119, 1855; *C. Heusser*, Pogg., xciv. 384, xcvii. 115. Binnito *Desc.*, Ann. d. M., V. viii. 389, 1855.

Isometric. Figures 3, 14, and others: observed planes: *O*, *I*, 2-2, with 1, $\frac{1}{2}$, and 6-6, on some crystals. Cleavage not distinct.

H.=4·5. G.=4·477. Lustre metallic. Color on fresh fracture black, sometimes brownish or greenish. Streak cherry-red. Brittle.

Comp.—From anal. 1, $\frac{3}{2}$ Ɵu $S + As^2S^3$=Sulphur 29·7, arsenic 31·1, copper 39·2=100. From anal. 2, Ɵu $S + \frac{1}{3}\,As^2S^5$, or like enargite. **Analyses:** 1, Uhrlaub (Pogg., xciv. 117); 2, Stockar-Escher (Kenng. Uebers., 1856–57, 174):

	S	As	Cu	Pb	Ag	Fe
1.	27·55	30·06	37·74	2·75	1·23	0·82=100·15 Uhr.
2.	32·73	18·98	46·24	—	1·91	—=99·86 S.-E.

Pyr.—In the closed tube, gives a sublimate of sulphid of arsenic; in the open tube a crystalline sublimate of arsenous acid, with sulphurous fumes. B.B. on charcoal gives an arsenical odor and a faint white coating, fuses with intumescence to a dull iron-black, magnetic globule, which, according to Wiser, is surrounded by a coating of oxyd of zinc. The globule yields metallic copper with soda.

Obs.—In dolomite, in the valley of Binnen, with realgar, orpiment, blende, pyrite, sartorite, and dufrenoysite.

111. BRONGNIARDITE. *Damour*, Ann. d. M., IV. xvi. 227, 1849.

Isometric. In octahedrons with truncated edges (1, I), Damour. Massive, without cleavage.

H. above 3. G.=5·950. Lustre like that of bournonite. Color and streak grayish-black.

Comp.—$Pb\,S + Ag\,S + Sb^2S^3$, or $2\,(Pb, Ag)\,S + Sb^2S^3$=Sulphur 19·4, antimony 29·5, silver 26·1, lead 25·0=100. **Analyses:** Damour (l. c.):

	S	Sb	Ag	Pb	Cu	Fe	Zn
1.	19·38	29·95	25·03	24·74	0·54	0·30	0·40=100·34.
2.	19·21	29·60	24·46	25·05	0·61	0·26	0·32=99·51.
3.	19·14	29·75	24·81	24·94	0·70	0·22	0·37=99·93.

Pyr., etc.—In the closed tube a feeble orange sublimate with a white one above; in the open tube fuses, affords an odor of sulphur and a white sublimate of oxyd of antimony. B.B. on charcoal decrepitates, fuses easily, giving off an odor of sulphur and white vapors; after roasting, yields a globule of silver, with a yellow coating of oxyd of lead. Rapidly attacked by concentrated nitric acid.

Obs.—From Mexico.

112. JAMESONITE. Grey antimony pt. *Jam.*, Syst., iii. 390, 1820. Axotomous Antimony-Glance *Jam.*, Man., 285. Axotomer Antimon-Glanz *Mohs*, Grundr., 586, 1824. Jamesonit *Haid.*, Trl. Mohs's Min., i. 451 (iii. 26), 1825.

Bleischimmer *Pfaff*, Schw. J., xxvii. 1. Pfaffite *Huot*, i. 192, 1841.

Antimonialisk Fäderers pt., Miner. antimonii plumosa pt., *Wall.*, 1747; Federerz *Germ.* Mine d'antimoine au plumos *Fr.*; Feather ore, Plumose Antimonial Ore, pt. (rest mostly Stibnite), *through last cent.* Antimoine sulfuré capillaire pt. [or var. of Stibnite] *H.*, Tr., 1801; Haarformiges Grauspiessglanzerz pt. *Karst.*, Tab., 52, 1800; Haarf. Antimonglanz *Mohs*, 1824, *Leonh.*, 1826. Federerz of Wolfsberg *H. Rose*, Pogg., xv. 471, 1829; *Beud.*, Tr., ii. 425, 1832. Federerz, var. of Jamesonite, *v. Kob.*, Char., ii. 175, 1831. Ch., 71, 1860.

Orthorhombic. $I \wedge I=101^\circ\ 20'$ and $78^\circ\ 40'$. Observed planes I, $i\text{-}\breve{i}$. Cleavage basal, highly perfect; I and $i\text{-}\breve{i}$ less perfect. Usually in acicular crystals. Also fibrous massive, parallel or divergent; also in capillary forms; also amorphous massive.

H.=2–3. G.=5·5–5·8; 5·564, from Cornwall, Haidinger; 5·616, from Estremadura, Schaffgotsch; 5·601, from Arany Idka, Löwe; 5·6788, massive, Ramm.

VAR.—*a*, well crystallized; *b*, fibrous or columnar, sometimes diverging; *c*, capillary, or cobweb-like; *d*, granular or compact.

The capillary is *feather ore* (Federerz *Germ.*) regarded as a species by nearly all the mineralogists of last century, but including capillary stibnite; made a variety of stibnite by v. Born, Karsten, Haüy, Mohs, Leonhard, and other authors, until 1829; and a distinct species again by most authors after the analysis by Rose in 1829; but referred to jamesonite by v. Kobell in 1830, and Rammelsberg in 1860. An *amorphous* variety occurs with the feather ore at Wolfsberg (anal. 7), for which Rammelsberg gives the hardness 3·0, and G.=5·6788.

Comp.—$2\,(\mathrm{Pb, Fe})\,\mathrm{S}+\mathrm{Sb}^2\mathrm{S}^3$=(if Fe : Pb=1 : 4) Sulphur 21·1, antimony 32·2, lead 43·7, iron 3·0=100. But excluding the iron as sulphid, Rose makes the formula $\frac{3}{2}\,\mathrm{Pb\,S}+\mathrm{Sb}^2\mathrm{S}^3$=Sulphur 20·7, antimony 34·8, lead 4·45=100. Von Zepharovich sustains the first formula (Sitz. Ak. Wien, 1867, 169). Analyses 5 to 10 of feather ore agree well with the preceding, whence Rammelsberg's reference to jamesonite.

Analyses: 1, 2, H. Rose (Pogg., viii. 101); 3, Schaffgotsch (Pogg., xxxviii. 403); 4, A. Löwe (Haid. Ber., i. 62); 5, H. Rose (Pogg., xv. 471); 6, Rammelsberg (Pogg., Ann., lxxvii. 24 · 7 Poselger (ib., Ramm., Min. Ch., 71); 8–10, C. Bechi (Am. J. Sci., II. xiv. 60):

10. " *capil.*	20·53	32·16	43·38	0·94	1·25	1·74=100 Bechi.

Pyr.—Same as for zinkenite

Obs.—*Jamesonite* occurs principally in Cornwall, associated with quartz and minute crystals of bournonite; occasionally also in Siberia, Hungary, at Valentia d'Alcantara in Spain, and Brazil Its perfect cleavage at right angles with the vertical axis is sufficient to distinguish it from the species it resembles. Named after Prof. Jameson of Edinburgh.

The *feather ore* occurs at Wölfsberg in the Eastern Harz; also at Andreasberg and Clausthal; at Freiberg and Schemnitz; in the Anhalt at Pfaffenberg and Meiseberg; in Tuscany, near Bottino; at Chonta in Peru.

Zundererz, or Bergzunderz [=Tinder Ore] of G. Lehmann (Mem. Ac. Berlin, 20, 1758), which is soft like tinder and dark dirty red in color, has been referred to kermesite, but proves to be jamesonite or feather ore mixed with red silver and arsenopyrite. Bornträger obtained in an analysis (J. pr. Ch., xxxvi. 40) S 19·57, As 12·60, Sb 16·88, Pb 45·06, Ag 2·56, Fe 4·52=96·19. From Andreasberg and Clausthal in the Harz.

113. DUFRENOYSITE. Dufrenoysite *Damour*, Ann. Ch. Phys., III. xiv. 379, 1845. Gotthardit *Ramm.*, Berz. Ch. Min., 229, 256, 1847. Arsenomelan and Scleroclase pt. *v. 108

Orthorhombic. $I\wedge I=93°\ 39'$, $O\wedge 1\text{-}\bar{i}=121°\ 30'$, $a:b:c=1{\cdot}6318:1:1{\cdot}0658$. Observed planes: O; vertical, I, $i\text{-}\breve{i}$, $i\text{-}\bar{i}$; domes, $\frac{1}{2}\text{-}\breve{i}$, $\frac{2}{3}\text{-}\breve{i}$, $1\text{-}\breve{i}$, $\frac{1}{4}\text{-}\bar{i}$, $\frac{1}{2}\text{-}\bar{i}$, $\frac{2}{3}\text{-}\bar{i}$, $1\text{-}\bar{i}$, $2\text{-}\bar{i}$; octahedral, 1, 2. $O\wedge 1\text{-}\breve{i}=123°\ 9'$, $O\wedge \frac{1}{2}\text{-}\breve{i}=142°\ 34'$, $O\wedge 2\text{-}\bar{i}=107°\ 2'$, $O\wedge 1=114°\ 5'$, $O\wedge 2=102°\ 36'$, $1\wedge 1\text{-}\bar{i}=141°\ 20\frac{1}{2}'$, $1\wedge 1\text{-}\bar{i}=138°\ 15'$, v. Rath. Usual in thick rectangular tables. Cleavage: O perfect. Also massive.

H.=3. G.=5·549, Damour; 5·5616, Landolt; 5·569, v. Rath. Lustre metallic. Color blackish lead-gray; streak reddish-brown. Opaque. Brittle.

Comp.—$2\,\mathrm{Pb\,S}+\mathrm{As^2S^3}$=Sulphur 22·10, arsenic 20·72, lead 57·18=100. Analyses: 1, 2, Damour (l. c.); 3, 4, Landolt & Berendies (Dissert. de Dufrenoysite, 1864, Pogg., cxxii. 374):

		S	As	Pb	Ag	Fe	Cu
1.	Binnen	22·49	20·69	55·40	0·21	0·44	0·31=99·54 Damour.
2.	"	22·30	20·87	56·61	0·71	0·32	0·22=101·03 Damour.
3.	"	23·27	21·76	53·62	0·05	0·30	——=99·0 L. & B.
4.	"	23·11	21·35	52·02	undet.		L. & B.

Analyses of dufrenoysite have been published by Uhrlaub and Nason (Pogg., c. 537), and by Stockar Escher (Kenng. Forsch., '56, '57, 176); but as they were made without discriminating the species, and give intermediate results, they are not cited here in detail. Peterson has also published two analyses (l. c.), and gives the following as the mean of 17 anal. by the chemists just mentioned and himself:

	S	As	Pb	Ag	Fe	Cu	
1.	24·31	24·25	50·86	0·41	——	?	=99·83

Peterson in one analysis obtained S 23·22, As 25·83, Pb 50·74, Ag 0·21; and in the other S 25·00, As 23·93, Pb 51·32, Ag 0·12. He makes the formula $[2\,\mathrm{Pb\,S}+\mathrm{As^2S^3}]+[\mathrm{Pb\,S}+\mathrm{As^2\,S^3}]=\mathrm{Pb\,S}+\frac{2}{3}\,\mathrm{As^2\,S^3}$.

Pyr., etc.—Easily fuses and gives a sublimate of sulphur and sulphuret of arsenic; in the open tube a smell of sulphur only, with a sublimate of sulphur in upper part of tube, and of arsenous acid below. On charcoal decrepitates, melts, yields fumes of arsenic and a globule of lead, which on cupellation yields silver.

Obs.—From the valley of Binnen in the St. Gothard Alps, in crystalline dolomite, along with sartorite, jordanite, binnite, realgar, orpiment, blende, pyrite. The crystals are sometimes an inch across.

Damour, who first studied the arsenio-sulphids of Binnen, analysed the massive ore and named it *dufrenoysite*. He inferred that the crystallization was monometric from some associated crystals, and so published it. This led von Waltershausen and Heusser to call the monometric mineral dufrenoysite, and the latter to name the trimetric *binnite*. Von Waltershausen, after studying the prismatic mineral, made out of the species *arsenomelan* and *scleroclase*, yet partly on hypothetical grounds. Recently it has been found that three orthorhombic minerals exist at the locality, as announced by vom Rath, who identifies one, by specific gravity and composition, with Damour's *dufrenoysite*; another he makes *scleroclase* of von Waltershausen (sartorite, p. 87); and the other he names *jordanite* (p. 88).

114. FREIESLEBENITE. Mine d'antimoine grise tenant argent (fr. Himmelsfürst) *de Lisle*, Descr. de Min., 35, 1773, Crist., iii. 54, 1783. Dunkles Weissgultigerz (id. loc., known since 1720) *Klapr.*, Beitr., i. 173, 1795. Schilf-Glaserz *Freiesleben*, Geogn. Arb., vi. 97, 1817. 109

Prisms longitudinally striated. Cleavage: *I* perfect. H.=2—2·5. G.=6—6·4; 6·194, Hausmann; 6·23, fr. Przibram, v. Payr. Lustre metallic. Color and streak light steel-gray, inclining to silver-white, also blackish lead-gray. Yields easily to the knife, and is rather brittle. Fracture subconchoidal—uneven.

Comp.—$5(Pb, Ag)S+2Sb^2S^3$ (fr. v. Payr's anal.)=, if Ag : Pb=3 : 4, Sulphur 18·6, antimony 25·9, lead 31·2, silver 24·3=100. Analyses: 1, 2, Wöhler (Pogg., xlvi. 146); 3, Escosura (Rev. Minera, vi. 358, Ann. d. M., V. viii. 495); 4, v. Payr (Jahrb. Min. 1860, 579):

	S	Sb	Pb	Ag	Fe	Cu
1.	18·77	27·72	30·00	22·18	0·11	1·62=100 W.
2.	18·72	27·05	30·08	23·78	——=99·60 W.	
3. Spain	17·60	26·83	31·90	22·45	——=98·78 Escosura.	
4. Przibram	18·41	27·11	30·77	23·08	0·68=100 Payr.	

Pisani refers here the massive dark *weissgültigerz* analyzed by Klaproth, who obtained (l. c.) S 22·00, Sb 21·50, Pb 41·00, Ag 9·25, Fe 1·75, $\dddot{A}l$ 1·00, $\ddot{S}i$ 0·75=97·25, considering part of the silver as here replaced by lead.

Pyr.—In the open tube gives sulphurous and antimonial fumes, the latter condensing as a white sublimate. B.B. on charcoal fuses easily, giving a coating, on the outer edge white, from antimonous acid, and near the assay yellow, from oxyd of lead; continued blowing leaves a globule of silver.

Obs.—With argentite, siderite, and galenite, in the Himmelsfürst mine, at Freiberg in Saxony, and Kapnik in Transylvania; at Ratieborzitz, the ore of which locality contains bismuth, according to Zincken; at Przibram in crystals, often twins, and 2 to 6 lines long; at Felsobanya; at Hiendelencina in Spain, with argentite, red silver, siderite, galenite, etc.

The crystals from Himmelsfürst are *triclinic*, according to Breithaupt (B. H. Ztg., xxv. 189). Chapman took his name *donacargyrite* from the British Museum, in 1843, knowing nothing of its origin. Such a name ought not to displace *freieslebenite*.

115. PYROSTILPNITE. Feuerblende *Breith.*, Char., 285, 333, 1832. Fireblende *Dana*, Min., 543, 1850. Pyrostilpnite, *Dana*.

Monoclinic. In delicate crystals grouped like stilbite. Observed planes, *I*, *i*-ì, 1-ì, 1-ì, 2-ì, B. & M.

$I \wedge I=139° 12'$. $2\text{-}\grave{\imath} \wedge 2\text{-}\grave{\imath}$, top, $=74°$. $i\text{-}\grave{\imath} \wedge 1\text{-}\grave{\imath}=123° 34'$.
$1\text{-}\grave{\imath} \wedge 1\text{-}\grave{\imath}$, top, $=112\ 52$. $i\text{-}\grave{\imath} \wedge 2\text{-}\grave{\imath}=148\ 42$. $1\text{-}\grave{\imath} \wedge 1\text{-}\grave{\imath}$, top, $=62\ 36$.

Cleavage: *i-ì*, and crystals flattened in this direction. Faces *i-ì* striated parallel to the clinodiagonal. Twins: plane of composition *i-ì* (orthodiagonal).

H.=2. G.=4·2—4·25. Lustre pearly-adamantine. Color hyacinth-red. Translucent. Sectile and somewhat flexible.

Comp.—Contains 62·3 per cent. of silver, along with sulphur and antimony (Plattner, l. c., 333).
Pyr.—Like pyrargyrite.
Obs.—From the Kurprinz mine near Freiberg; Andreasberg; Przibram.
Named from πῦρ, *fire*, and στιλπνός, *shining*, in allusion to its fire-like color.

116. RITTINGERITE. Rittingerit *Zippe*, Ber. Ak. Wien, ix. 2, 345, 1852.

Monoclinic; $C=88° 26'$. In small rhombic tables with replaced basal edges. Observed planes: O, $\frac{1}{2}$, I, ± 6, ± 1. Observed angles: $O \wedge I=91° 24'$, $I \wedge I=126° 18'$, $O \wedge 1=132° 24'$, $O \wedge -1=130° 50'$, $1 \wedge -1=96° 20'$, $O \wedge -6=98° 30'$, $O \wedge \frac{1}{2}=150°$, $-1 \wedge -1=140° 1'$. Cleavage: O imperfect.

H.=1·5—3. Lustre submetallic-adamantine. Plane O blackish-brown in the larger crystals, less dark in the more minute; other parts iron-black. Translucent and dull honey-yellow to hyacinth-red in the direction of the axis. Streak orange-yellow. Brittle.

Comp.—Probably a compound of sulphid of silver and antimony.
Pyr.—B.B. same as with pyrargyrite; fuses very easily, gives an arsenical odor, and finally a globule of pure silver.
Obs.—From Joachimsthal, in small crystals.

117. PYRARGYRITE.

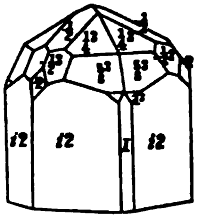
11

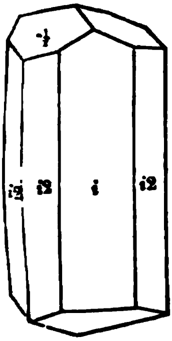


Rhombohedral. Opposite extremities of crystals often unlike. $R \wedge R=108° 42'$, B. & M., $O \wedge R=137\ 42'$; $a=0·788$. Observed planes in this and the following species: basal and prismatic, O, I, $i\text{-}2$, $i\text{-}\frac{5}{3}$, $i\text{-}\frac{5}{4}$, $i\text{-}\frac{23}{16}$; rhombohedral, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{7}{16}$, $\frac{5}{8}$, R (or 1), $\frac{5}{2}$, 4, -14, -5, $-\frac{7}{2}$, -2, $-\frac{5}{4}$, -1, $-\frac{1}{2}$, $-\frac{1}{5}$, $-\frac{1}{8}$; pyramidal, $\frac{2}{3}\text{-}2$, $\frac{4}{3}\text{-}2$,; scalenohedral, $\frac{1}{7}^{5}$, $\frac{1}{5}^{5}$, $\frac{1}{5}^{\frac{17}{5}}$, $\frac{1}{4}^{3}$, $\frac{1}{4}^{4}$, $\frac{1}{4}^{7}$, $\frac{5}{14}^{\frac{7}{5}}$, $\frac{1}{3}^{3}$, $\frac{1}{3}^{\frac{17}{5}}$, $\frac{4}{13}^{\frac{7}{4}}$, $\frac{2}{5}^{2}$, $\frac{2}{5}^{3}$, $\frac{2}{5}^{4}$, $\frac{1}{2}^{3}$, $\frac{1}{2}^{\frac{11}{5}}$, $\frac{5}{8}^{\frac{5}{3}}$, $\frac{5}{8}^{\frac{11}{5}}$, $\frac{5}{8}^{3}$, $\frac{2}{3}^{2}$, $\frac{2}{3}^{\frac{5}{3}}$, $1^{\frac{5}{3}}$, $1^{\frac{7}{5}}$, 1^{3}, $1^{\frac{7}{3}}$, 1^{4}, 1^{5}, $1^{\frac{17}{5}}$, 1^{9}, 1^{7}, $\frac{11}{8}^{\frac{17}{11}}$, 2^{2}, $\frac{11}{8}^{\frac{23}{11}}$, $\frac{5}{2}^{\frac{9}{5}}$, $\frac{2}{3}^{3}$, $10^{\frac{5}{3}}$, $-8^{\frac{5}{4}}$, $-5^{\frac{7}{5}}$, $-5^{\frac{23}{16}}$, $-5^{\frac{11}{5}}$, $-5^{\frac{13}{5}}$, $-4^{\frac{5}{3}}$, $-\frac{7}{2}^{\frac{11}{7}}$, $-\frac{2}{7}^{4}$, $-\frac{11}{4}^{\frac{17}{11}}$, $-\frac{5}{3}^{\frac{9}{5}}$, -2^{2}, -2^{3}, $-2^{\frac{7}{3}}$, $-\frac{5}{4}^{\frac{13}{5}}$, $-1^{\frac{7}{5}}$, $-\frac{4}{5}^{3}$, $-\frac{2}{7}^{2}$ $-\frac{1}{2}^{\frac{11}{5}}$, $-\frac{1}{2}^{3}$, $-\frac{1}{2}^{5}$, $-\frac{1}{2}^{\frac{11}{5}}$, $-\frac{1}{2}^{\frac{5}{3}}$, $\frac{1}{5}^{3}$, $\frac{1}{5}^{9}$, $\frac{1}{20}^{13}$, Q. Sella.

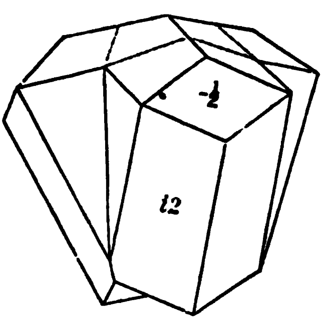
$O \wedge \frac{1}{2} = 155°\ 32'$ $\frac{1}{2} \wedge \frac{1}{2} = 137°\ 58'$ $R \wedge \frac{1}{2} = 144°\ 21'$
$O \wedge 1^{3} = 112\ \ 33'$ $i\text{-}2 \wedge R = 125\ \ 39$ $R \wedge \frac{1}{4}^{3} = 164\ \ 5$
$O \wedge 1^{7} = 100\ \ 14$ $i\text{-}2 \wedge 1^{3} = 155\ \ 4$ $i\text{-}2 \wedge i\text{-}2 = 120.$

Cleavage: *R* rather imperfect. Twins: composition-face $-\frac{1}{2}$, as in f. 113, which consists of four individuals; *O* or basal plane, as in f. 114; also *R* and *I*. Also massive, structure granular, sometimes impalpable.

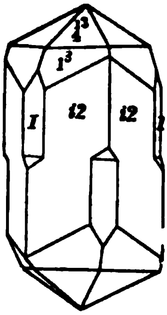
112



113



114



H.=2—2·5. G.=5·7—5·9. Lustre metallic-adamantine. Color black, sometimes approaching cochineal-red. Streak cochineal-red. Translucent—opaque. Fracture conchoidal.

Comp.—$3\,\mathrm{Ag\,S}+\mathrm{Sb}^{2}\,\mathrm{S}^{3}$=Sulphur 17·7, antimony 22·5, silver 59·8=100. Analyses: 1, Bonsdorff (Ak. H. Stockh., 1821, 338); 2, Wöhler (Ann. d. Pharm., xxvii. 157); 3, Böttger (Ramm. Handw., ii. 106); 4, F. Field (Q. J. Ch. Soc., xii. 12):

	S	Sb	Ag
1. Andreasberg	16·61	22·85	58·95, gangue 0·30=98·70 Bonsdorff.
2. Mexico	18·0	21·8	60·2=100 Wöhler.
3. Zacatecas, Mex.	17·76	24·59	57·45=99·80 Böttger.
4. Chili	17·45	23·16	59·01=99·62 Field.

Henckel found arsenic in ruby silver (Pyritol., 169, 1725), and both light and red silver ores were afterwards considered arsenical, until Klaproth's analysis, detecting antimony alone, in 1794 (Beitr., i. 141); after this both were supposed to be antimonial, until Proust, in 1804 (J. de Phys., lix. 403) showed that there were two species, an antimonial and an arsenical.

Pyr., etc.—In the closed tube fuses and gives a reddish sublimate of sulphid of antimony; in the open tube sulphurous fumes and a white sublimate of oxyd of antimony. B.B. on charcoal fuses with spirting to a globule, gives off sulphid of antimony, coats the coal white, and the assay is converted into sulphid of silver, which, treated in O.F., or with soda in R.F., gives a globule of fine silver. In case arsenic is present it may be detected by fusing the pulverized mineral with soda on charcoal in R.F.

Decomposed by nitric acid with separation of sulphur and antimonous acid.

Obs.—The *dark-red silver ore* occurs principally with calcite, native arsenic, and galenite, at Andreasberg in the Harz; also in Saxony, Hungary, Norway, at Gaudalcanal in Spain, and in Cornwall. In Mexico it is worked extensively as an ore of silver. In Chili it is found in crystals at mine Dolores and Chañarcillo near Copiapo. In Nevada, at Washoe in Daney Mine; in Ophir mine, rare; abundant about Austin, Reese river, but no good crystals; at Poorman lode, Idaho, in masses sometimes of several hundred weight, along with cerargyrite.

A *light-red* ore from Andreasberg, according to Zincken, contains no arsenic. A *gray* ore from the same locality, contains both arsenic and antimony, and may be miargyrite. On cryst. of pyrargyrite, see Q. Sella, Acad. Sci. Torino, 8vo, 1856.

Alt.—Occurs like proustite, changed to argentite (Ag S); to pyrite; so-called argentopyrite silver.

118. PROUSTITE. Argentum rude rubrum translucidum carbunculis simile, *Germ.* Durchsichtig Rodtguldenerz, *Agric.*, 362, Interpr., 462, 1546. Argentum rubri coloris pellucidum, Schön Rubin Rothguldenerz, *Gesner*, Foss., 62, 1565. Minera argenti rubra pellucida *Wall.*, 311, 1747. Ruby Silver Ore pt. *Hill.* Argent rouge arsenicale *Proust*, J. de Phys., lix. 404, 1804. Lichtes Rothgültigerz pt., Arsenikalisches id., Arseniksilberblende, *Germ.* Rubinblende pt. Arsenical Silver Ore; Light Red Silver Ore. Proustite *Beud.*, Tr., ii. 445, 1832.

Rhombohedral. $R \wedge R=107° 48'$, $O \wedge R=137° 9'$; $a=0{\cdot}78506$. Also granular massive.

H.=2—2·5. G.=5·422—5·56. Lustre adamantine. Color cochineal-red. Streak cochineal-red, sometimes inclined to aurora-red. Subtransparent—subtranslucent. Fracture conchoidal—uneven.

Comp.—$3\,Ag\,S+As^2\,S^3$=Sulphur 19·4, arsenic 15·2, silver 65·4=100. **Analyses:** 1, H. Rose (Pogg., xv. 472); 2, F. Field (Q. J. Chem. Soc., xii. 12):

1. Joachimsthal	S 19·51	As 15·09	Ag 64·67	Sb 0·69=99·96 Rose.
2. Chili	19·81	15·12	64·88=99·81 Field.	

Pyr., etc.—In the closed tube fuses easily, and gives a faint sublimate of sulphid of arsenic; in the open tube sulphurous fumes and a white crystalline sublimate of arsenous acid. B.B. on charcoal fuses and emits odors of sulphur and arsenic; by prolonged heating in O.F., or with soda in R.F., gives a globule of pure silver. Some varieties contain antimony.

Decomposed by nitric acid, with separation of sulphur and arsenous acid.

Obs.—Occurs at Freiberg, Johanngeorgenstadt, Marienberg, and Annaberg; at Joachimsthal in Bohemia; Wolfach in Baden; Markirchen in Alsace; Chalanches in Dauphiné; Guadalcanal in Spain; in Mexico; Peru; Chili, near Copiapo, at Chanarçillo, some crystals 3 in. long (D. Forbes.) In Nevada, in the Daney mine, and in Comstock lode, but rare; in veins about Austin, Lander Co; in microscopic crystals in Cabarrus Co., N. C., at the McMakin mine; in Idaho, at the Poorman lode, with pyrargyrite, native silver and gold, and cerargyrite.

Named after the French chemist, J. L. Proust.

Alt.—Occurs altered to pyrrhotite, Breith.

119. BOURNONITE. Ore of Antimony (fr. Endellion) *P. Rashleigh*, Spec. Brit. Min., i. 34, pl. xix., 1797. Triple Sulphuret of Lead, Antimony, and Copper *Bournon* (with figs.), Phil. 10. Huasco	20·45	26·21	40·76	12·52=99·94 Field. G.=5·80.

The Meiseberg mineral (No. 4) is light-gray, and occurs in tabular crystals, with an uneven conchoidal fracture, and submetallic lustre. G.=5·703, Zincken; 5·726 and 5·792, Bromeis; 5·779, Rammelsberg.

Another variety (No. 3) is iron-black, with the faces of a rhombic octahedron largely developed. Fracture conchoidal. Lustre metallic. G.=5·822 and 5·847, Bromeis; 5·844, Zincken; 5·863, Rammelsberg.

The Wolfsberg ore (No. 5) is iron-black. The crystals are rectangular prismatic. Fracture conchoidal. Lustre metallic. G.=5·726, Rammelsberg; 5·796, Zincken; 5·801 and 5·855, Bromeis.

For Zirkel on cryst. and history, see Ber. Ak. Wien, xlv. 431, 1862. Zirkel makes the macrodiagonal of the crystal above the vertical axis; and in this we have not followed him, because the above is strictly the *normal* position for the vertical axis, or that which homology with the cube requires, since *O* ∧ 1-ĭ and *O* ∧ 1-ī are near 135°. The faces *i-ī* and *i-ĭ* are homologous with the cubic faces, and *I*, *I* with the dodecahedral, the angle between which, either side of *i-ī*, is near 90°.

Pyr., etc.—In the closed tube decrepitates, and gives a dark-red sublimate. In the open tube gives sulphurous acid, and a white sublimate of oxyd of antimony. B.B. on charcoal fuses easily, and at first coats the coal white, from antimonous acid; continued blowing gives a yellow coating of oxyd of lead; the residue, treated with soda in R.F., gives a globule of copper.

Decomposed by nitric acid, affording a blue solution, and leaving a residue of sulphur, and a white powder containing antimony and lead.

Obs.—Occurs in the mines of Neudorf in the Harz (which include the Meiseberg localities), where the crystals occasionally exceed an inch in diameter; also at Wolfsberg, Clausthal, and Andreasberg in the Harz; with quartz, tetrahedrite, and phosphorescent blende, at Kapnik in Transylvania, in flattened crystals; at Servoz in Piedmont, associated with pearl spar and quartz. Other localities are the parish of Bräunsdorf and Gersdorf in Saxony, Olsa in Carinthia, etc.; Endellion at Wheal Boys in Cornwall, where it was first found, and hence called *endellione*, by Count Bournon, after whom it was afterward named; in Mexico; at Huasco-Alto in Chili; at Machacamarca in Bolivia; in Peru.

Alt.—Occurs altered to cerussite, malachite, azurite, and also (as Rammelsberg has shown) to the mineral called *wölchite*, which occurs in similar crystals, with the same hardness and same sp. gr. (5·88—5·94 Ramm.). It was originally from Wölch in Carinthia, but occurs also at Olsa, with true bournonite.

Schrötter, in his analysis of wölchite from Wölch, obtained (Baumgartn. ZS., viii. 284) S 28·60, Sb 16·65, As 6·04, Pb 29·90, Cu 17·35, Fe 1·40=99·94. Rammelsberg found, as the mean of 4 analyses (Min. Chem., 80), S 16·81, Sb 24·41, Pb 15·59, Cu 42·83, Fe 0·36=100, excluding the percentage of mixed carbonate, sulphate, and antimonial salts of lead and copper, and some water.

120. STYLOTYPITE. Stylotyp *v. Kobell*, Ber. Ak. München, 1865, i. 163, 1865. Cañutillo *Chilian miners.*

Orthorhombic. *I* ∧ *I* about 92½°, near that of Bournonite. Twins: cruciform, angle of intersection near 90°. Cleavage: none distinct.

H.=3. G.=4·79. Lustre metallic. Color iron-black; streak black. Fracture imperfectly conchoidal, uneven.

Comp.—3 (Ɵu, Ag, Fe) S + Sb^2S^3, the species being an iron-silver-copper bournonite (ratio Ɵu + Ag : Fe=2 : 1, and Ɵu : Ag=6 : 1)=Sulphur 24·9, antimony 31·6, copper 28·2, silver 8·0, iron 7·3=100. Analysis: v. Kobell (l. c.):

S	Sb	Cu	Fe	Ag
24·30	30·53	28·00	7·00	8·30, Pb, Zn *tr.*=98·13

Pyr., etc.—B.B. decrepitates, and fuses very easily. On charcoal a steel-gray globule, which is magnetic; fumes of antimony, and some lead coating the coal.

Obs.—From Copiapo in Chili.

Named from στῦλος, *column*, and τύπος, *form*, in allusion to the columnar form, in which it differs from tetrahedrite, although approaching it in composition.

121. WITTICHENITE. Kupferwismutherz *Selb.*, Denks. d'Aerzte u. Nat. Schwab., i. 419; *Klapr.*, Beitr., iv. 91, 1807. 7. "	(⅓) 18·69	51·40	28·82	0·91=99·82 Schneider.
8 "	18·21	41·53	36·91	3·13=99·78 Hilger.

Pyr.—In the open tube gives sulphurous fumes and a white sublimate of sulphate of bismuth. B.B. on charcoal fuses easily, at first throws out sparks, and coats the coal with oxyd of bismuth; the residue with soda in R.F. gives a globule of metallic copper. Soluble in muriatic acid, with evolution of sulphuretted hydrogen; decomposed by nitric acid, with separation of sulphur.

Obs.—From cobalt mines with barite, near Wittichen in Gallenbach, Baden; analyses 4–6 are of specimens from the Neuglück mine, and 7, 8, from the Daniel mine; also at Zell, near Wolfach; at Christophsaue near Freudenstadt.

Alt.—Undergoes easy alteration, becoming yellowish-brown, then red and blue externally, forming apparently covellite; also changing to a greenish earthy mineral, which is a mixture of malachite, oxyd of bismuth, and hydrated oxyd of iron; also to an earthy yellow bismutite and bismuth-ochre. (Sandberger, Jahrb. Min., 1865, 274.)

122. BOULANGERITE. Plomb antimonié sulfuré *Boulanger*, Ann. d. M., III. vii. 575, 1835. Schwefelantimonblei *Germ.* Sulphuret of Antimony and Lead. Boulangerit *Thaulow*, Pogg., xli. 216, 1837; *Hausm.*, ib., xlvi. 281. Embrithite, Plumbostib, *Breith.*, J. pr. Ch., x. 442, 1837.

In plumose masses, exhibiting in the fracture a crystalline structure; also granular and compact.

H.=2·5–3. G.=5·75–6·0. Lustre metallic. Color bluish lead-gray; often covered with yellow spots from oxydation.

Comp.—$3\,Pb\,S + Sb^2S^3$=Sulphur 18·2, antimony 23·1, lead 58·7=100. Analyses: 1, Boulanger (Ann. d. M., III. vii. 575); 2, Thaulow (Pogg., xli. 216); 3, Bromeis (Pogg., xlvi. 281); 4, Brüel (ib.); 5, Abendroth (Pogg., xlvii. 493); 6, Rammelsberg (3d Suppl., 28); 7, 8, E. Bechi (Am. J. Sci., II. xiv. 60); 9, Genth (private contrib.):

9. Union Co., Nev.	17·91	26·85	54·82, Fe 0·42, Ag *tr.*=100 Genth.

Pyr.—Same as for zinkenite.

Obs.—Quite abundant at Molières, department of Gard, in France; also found at Nasafjeld in Lapland; at Nertschinsk; Ober-Lahr in Sayn-Altenkirchen; Wolfsberg in the Harz; near Bottino in Tuscany, both massive, acicular, and fibrous.

Embrithite is from the locality of boulangerite at Nertschinsk, and is probably the same species. It is granular in texture, of a lead-gray color, has G.=6·29—6·311; and contains, according to Plattner (l. c.), lead 53·3, copper 0·8, silver 0·04, along with antimony and copper. Named from ἐμβριθής, *heavy*.

Plumbostib is also from Nertschinsk. It consists, according to Plattner, of antimony, arsenic, sulphur, a little iron, with 58·8 p. c. of lead; and appears to be boulangerite. Named from *plumbum* and *stibium*.

123. KOBELLITE. Kobellit *Sätterberg*, Ak. H. Stockh., 188, 1839; Jahresb., xx. 215.

Resembles gray antimony, but brighter in lustre; structure radiated.

G.=6·29–6·32, Sätterberg; 6·145, Ramm. Soft. Color blackish lead-gray to steel-gray. Streak black.

Comp.—$(3\,Pb\,S + Bi^2S^3) + (3\,Pb\,S + Sb^2S^3)$ Ramm.=$3\,Pb\,S + (Bi, Sb)^2S^3$=Sulphur 16·8, bismuth 18·2, antimony 10·6, lead 54·4=100.

Analyses: 1, Sätterberg (loc. cit.); 2, Rammelsberg (J. pr. Ch., lxxxvi. 340):

	S	Sb	Bi	Pb	Fe	Cu
1.	17·86	9·24	27·05	40·12	2·96	0·80, gangue 1·45=99·48 S.
2.	17·47	10·43	20·52	48·78	1·55	——=98·75 R.

Rammelsberg's analysis represents the composition of pure kobellite after excluding 5·61 p. c cobaltiferous pyrites, and 3·67 p. c. chalcopyrite, present as mechanical impurities in the specimen analyzed.

Pyr., etc.—B.B. in the closed tube fuses and gives a faint sublimate of sulphur. In the open tube, sulphurous fumes and a sublimate of oxyd of antimony. On charcoal fuses and forms a coating, the outer edge of which is white from antimonous acid, etc., and near the assay dark yellow. Soluble in concentrated muriatic acid, with evolution of sulphuretted hydrogen.

Obs.—From the cobalt mine of Hvena in Sweden, associated with actinolite, chalcopyrite, and small reddish-white crystals of a cobaltiferous mispickel (Kobaltarsenikkies). Named after von Kobell.

124. AIKINITE. Nadelerz *Mohs*, Null's Kab., iii. 726, 1804. Bismuth sulfuré plumbo-cuprifère *H.*, Tabl., 105, 1809. Needle Ore; Acicular Bismuth; Cupreous Bismuth. Aikinite *Chapman*, Min., 127, 1843. Patrinite *Haid.*, Handb., 568, 1845. Belonit *Glock.*, Syn., 27, 1847. Aciculite *Nicol*, Min., 487, 1849.

Orthorhombic. $I\wedge I=110^\circ$ nearly, Hörnes. Crystals long, imbedded, acicular, longitudinally striated. Also massive.

H. = 2—2·5. G.=6·1—6·8; 6·757, Frick. Lustre, metallic. Color blackish lead-gray, with a pale copper-red tarnish. Opaque. Fracture uneven.

Comp.—$(3\,\text{Ꞓu}\,S+Bi^2\,S^3)+2\,(3\,Pb\,S+Bi^2\,S^3)=3\,(\text{Ꞓu},Pb)\,S+Bi^2\,S^3$=Sulphur 16·7, bismuth 36·2, lead 36·1, copper 11·0=100. Supposed to be isomorphous with bournonite.

Analyses: 1, 2, Frick (Pogg., xxxi. 529); 3, Chapman (Phil. Mag., III. xxxi. 541); 4, Hermann (J. pr. Ch., lxxv. 452):

	S	Bi	Pb	Cu	Ni
1. Beresof	16·05	34·62	35·69	11·79	——=98·15 Frick; G.=6·757.
2. "	16·61	36·45	36·05	10·59	——=99·70 Frick.
3. "	18·78	27·93	40·10	12·53	——=99·64 Chapman; G.=6·1.
4. "	16·50	34·87	36·31	10·97	0·36, Au 0·09=100 Herm.

Pyr., etc.—In the open tube gives sulphurous fumes, and also a white sublimate, which may be fused into clear drops that are white on cooling; the assay becomes surrounded with a black fused oxyd, which on cooling is transparent and greenish-yellow. B.B. on charcoal fuses and gives a white coating, yellow on the edge nearest the assay; with the fluxes, reactions for copper, and after long blowing a globule of metallic copper.

Decomposed by nitric acid, with separation of sulphur and sulphate of lead.

Obs.—Occurs at Beresof near Katharinenburg, Urals, with gold, malachite, and galenite, in white quartz. In the United States, in the gold region of Georgia (?) in slender crystals, some of which have a centre of gold, and others are altered to bismuth-ochre or cupreous carbonate of bismuth (Genth, Am. J. Sci., II. xxxiii. 190); probably at Gold Hill, Rowan Co., N. Carolina.

Alt.—Occurs, as just stated, altered to bismuth-ochre and native gold.

Retzbanyite *Hermann* (J. pr. Ch., lxxv. 450, 1859). A lead-gray ore of bismuth, occurring mixed with the product of its alteration, at Retzbanya in Hungary It is without trace of crystallization; H.=2·5; G.=6·21. Afforded Hermann, S 11·93, O 7·14, Bi 38·38, Pb 36·01, Ag 1·93, Cu 4·22=99·61.

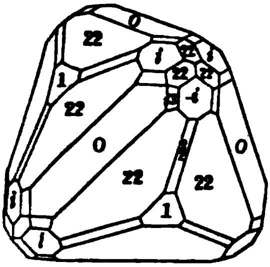
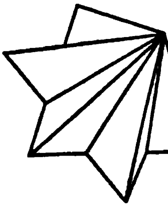
Isometric; tetrahedral. Observed planes: those of f. 117, with also 4-4, 5-$\frac{5}{3}$, $\frac{8}{5}$-$\frac{8}{5}$, $\frac{12}{5}$-$\frac{12}{7}$; on one crystal from Kahl, 1, 2-2, $\frac{8}{5}$-$\frac{8}{5}$, $\frac{12}{5}$-$\frac{12}{7}$, −1, −2-2, −4-4. −5-$\frac{5}{3}$, with *O* and *i*, Hessenberg. Twins, composition face octahedral, producing, when the composition is repeated, the form in f. 119, the simpler condition of which is shown in f. 118, a solid seemingly made of two interpenetrating tetrahedrons; also forms similar to f. 62, 63, p. 21, in which the tetrahedrons are united in a reversed position. Also massive; granular, coarse, or fine; compact or crypto-crystalline.

H.=3−4·5. G.=4·5−5·11. Lustre metallic. Color between light flint-gray and iron-black. Streak generally same as the color; sometimes inclined to brown and cherry-red. Opaque; sometimes subtranslucent in very thin splinters, transmitted color cherry-red. Fracture subconchoidal —uneven. Rather brittle.

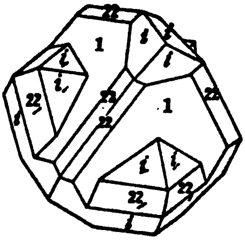
117



118



119



Comp., Var.—4 Cu S+Sb^2 S^3, with part of the copper often replaced by iron, zinc, silver, or quicksilver, and rarely cobalt, and part of the antimony by arsenic, and rarely bismuth; whence the general formula 4 (Ꞓu, Fe, Zn, Ag, Hg)+(Sb, As, Bi)^2 S^3. Ratio Ag+Ꞓu : Zn+Fe generally =2:1. There are thus:

A. An antimonial series;
B. An arsenio-antimonial series;
C. A bismuthic arsenio-antimonial;

besides an *arsenical*, in which arsenic replaces all the antimony, and which is made into a distinct species named *tennantite*. In the analyses below the largest amount of arsenic given is about 20 p. c. (anal. 20.)

Var. 1. *Ordinary.* Containing little or no silver (Cupreous tetrahedrite; Kupferfahlerz, Lichtes Fahlerz, Graugiltigerz pt., *Germ.*). Color steel-gray to dark gray. G.=5—5·8.

2. *Argentiferous; Freibergite* (Syn. above). Light steel-gray, sometimes iron-black. G.=4·8—5, or less.

3. *Mercuriferous; Schwatzite* (Syn. above). Color gray to iron-black. G.=5—5·6. Breithaupt designates the ore of Schwatz alone *schwatzite*, having G.=5·107; that of Kotterbach and others

having G.=5·2—5·28, *spaniolite*; that of Moschellandsberg, having G.=5·5—5·566, *hermesite* (from the Greek for Mercurius), it affording Hg 24·10, Ag 5·62. But another ore from Moschellandsberg contains Hg 17·32 p. c., and no silver, a fact which shows the futility of attempts to divide up tetrahedrite into distinct groups or species.

4. *Platiniferous.* An ore from Guadalcanal, Spain, contains, according to Vauquelin, 1—10 p. c. of platinum.

In distinguishing these varieties, color, as above seen, is a poor criterion, it depending largely on the amount of iron present. The argentiferous ores are commonly the lighter gray, but not always so.

Analyses: *Ordinary.* 1. Kerl (B. H. Ztg., 1853, No. 2); 2, Bromeis (Pogg., lv. 117); 3, Amelung (Ramm., 3d Suppl., 51); 4, Klaproth (Beitr., iv. 61); 5, H. Rose (Pogg., xv. 576); 6, C. G. in anal. 12, 4·73; 18, 4·58; 21, 4·87; 27, 4·89—4·946; 28, 4·526; 29, 4·852; 35, 4·582; 36, 4·762; 37, 4·733; 39, 5·107; 41, 4·84; 44, 4·605; 45, 5·107; 46, 5·356.

Cobalt occurs in the ore of Schwarzwald, Moschellandsberg, Schottenhöfen near Zell, Clara near Schapbach, and others.

Pyr., etc.—Differ in the different varieties. In the closed tube all fuse and give a dark-red sublimate of sulphid of antimony; when containing mercury, a faint dark-gray sublimate appears at a low red heat; and if much arsenic, a sublimate of sulphid of arsenic first forms. In the open tube fuses, gives sulphurous fumes and a white sublimate of antimony; if arsenic is present, a crystalline volatile sublimate condenses with the antimony; if the ore contains mercury it condenses in the tube in minute metallic globules. B.B. on charcoal fuses, gives a coating of antimonous acid and sometimes arsenous acid, oxyd of zinc, and oxyd of lead; the arsenic may be detected by the odor when the coating is treated in R.F.; the oxyd of zinc assumes a green color when heated with cobalt solution. The roasted mineral gives with the fluxes reactions for iron and copper; with soda yields a globule of metallic copper. To determine the presence of a trace of arsenic by the odor, it is best to fuse the mineral on charcoal with soda. The presence of mercury is best ascertained by fusing the pulverized ore in a closed tube with about three times its weight of dry soda, the metal subliming and condensing in minute globules. The silver is determined by cupellation.

Decomposed by nitric acid, with separation of sulphur and antimonous and arsenous acids.

Obs.—The Cornish mines, near St. Austell, have afforded large tetrahedral crystals, with rough and dull surfaces. More brilliant crystallizations occur at the Levant mine near St. Just, at Condurrow mine and other places in Cornwall; at Andreasberg and Clausthal in the Harz; Kremnitz in Hungary; Freiberg in Saxony; Przibram in Bohemia; Kahl in Spessart; Kapnik in Transylvania; Dillenburg in Nassau; and other localities mentioned above.

The ore containing mercury occurs in Schmölnitz, Hungary; at Poratsch, Zavatka, and Kotterbach near Iglo; at Schwatz in the Tyrol; and in the valleys of Angina and Castello in Tuscany.

Tetrahedrite is found in America; in Mexico, at Durango, etc.; at various mines in Chili; in Bolivia; at the Kellogg mines, 10 m. N. of Little Rock, Arkansas, with galenite. In California in Mariposa Co., in the Pine Tree gold vein and others; in Shasta Co., Chicago claim. In Nevada, abundant at the Sheba and De Soto mines, Humboldt Co., massive and rich in silver (the De Soto containing 16·4 p. c. of silver, Allen); near Austin in Lander Co.; in Arizona at the Heintzelman mine, containing 1½ p. c. of silver; at the Santa Rita mine.

Alt.—Chalcopyrite, malachite, azurite, amalgam, bournonite, erythrite, cinnabar, covellite, occur as pseudomorphs after tetrahedrite. Also a red pulverulent mineral, consisting of an acid of antimony, oxyd of copper or oxyd of mercury, etc. (See *Ammiolite.*)

Annivite of Brauns (Mitth. nat. Ges. Bern, 1854, Kenngott's Ueb., 1855), from the Annive valley in the Valais, is probably, according to Kenngott, only tetrahedrite. Brauns obtained S 23·75, Sb 8·80, As 10·96, Bi 4·94, Cu 35·57, Fe 3·85, Zn 2·01, quartz 9·40=100·28. Excluding the quartz, the composition corresponds nearly to $4\ \mathrm{R}\ \mathrm{S}+(\mathrm{As}^2\ \mathrm{S}^3,\ \mathrm{Sb}^2\ \mathrm{S}^3,\ \mathrm{Bi}^2\ \mathrm{S}^3)$. It occurs only massive, and is mixed with chalcopyrite.

Studerite of Fellenberg (Mitth. nat. Ges., Bern, 1864, 178) is a similar compound (Kenng., Min. d. Schweiz, 402). It is from Ausserberg in the Upper Valais, Switzerland. Fellenberg obtained, S 24·70, Sb 15·43, As 11·38, Bi 0·57, Cu 37·89, Fe 2·73, Zn 5·06, Pb 0·38, Ag 0·95, gangue 1·81. G.=4·657.

A. FIELDITE.—An ore from mine Altar, 30 leagues from Coquimbo, afforded F. Field (Q. J. Ch. Soc., iv. 332), S 30·35, As 3·91, Sb 20·28, Cu 36·72, Zn 7·26, Fe 1·23, Ag 0·075, Au 0·003. It is soft, of greasy appearance, greenish-gray, slightly reddish, with powder bright-red. Domeyko considers it impure with blende, pyrite, and galenite. Ettling observes (ib., vi. 140) that the constitution is analogous rather to enargite than tetrahedrite, corresponding to the formula $4\ (\mathrm{Ȼu},\ \mathrm{Zn},\ \mathrm{Fe},\ \mathrm{Ag})\ \mathrm{S}+(\mathrm{Sb},\ \mathrm{As}^2)\ \mathrm{S}^5$. Kenngott has named it *Fieldite*.

B. APHTHONITE (or Aftonite) Svanberg.—A steel-gray ore, resembling tetrahedrite, if not identical with it; H.=3; G.=4·87; and it contains, according to Svanberg (Berz. Jahresb., xxvii. 236), S 30·05, Sb (with *tr.* of As) 24·77, Cu 32·91, Ag 3·09, Zn 6·40, Fe 1·31, Co 0·49, Pb 0·04, gangue 1·29=100·35. Ratio of sulphid of antimony to that of the other metals, 3 : 6·4. From Wermland in Sweden.

126. POLYTELITE *Glock.*, Syn., 31, 1847. (Weissgültigerz pt.) An ore consisting mainly of lead, silver, antimony, and sulphur. Glocker cites Rammelsberg's analysis (Pogg., lxviii. 515, Min. Ch., 99) of an ore from Hoffnung Gottes mine near Freiberg, a fine-granular ore, having G. =5·438—5·465, apparently homogeneous, but somewhat mixed with blende and pyrite. Klaproth analyzed a related *weissgültigerz* from the Himmelsfürst mine near Freiberg (Beitr. i. 166).

	S	Sb	Cu	Fe	Zn	Pb	Ag
1. Himmelsfürst, *light*	13·21	8·50	——	2·42	——	51·81	22·00=97·94 K.
2. " *dark*	22·39	21·88	——	1·79	——	41·73	9·41=97·20 K.
3. Hoff. G.	22·53	22·39	0·32	3·83	6·79	38·36	5·78=100 R.

Rammelsberg makes the mineral, from his analysis, a silver-lead tetrahedrite, with the formula $4\ (\mathrm{Pb},\ \mathrm{Ag},\ \mathrm{Fe},\ \mathrm{Zn})\ \mathrm{S}+\mathrm{Sb}^2\ \mathrm{S}^3$, in which the ratio Fe : Zn : Pb+Ag=2 : 3 : 6, and Pb : Ag=7 : 1.

127. TENNANTITE. Gray Sulphuret of Copper in dodecahedral crystals *Sowerby*, Brit. Min., 1817. Tennantite *Wm. & R. Phillips*, Q. J. Sci., vii. 95, 100, 1819. Arsenikalfahlerz *Germ.* Kupferblende *Breith.*, Char., 131, 251, 1823, Pogg., ix. 613, 1827. Sandbergerit *Breith.*, B. H. Ztg., xxv. 187, 1866.

Isometric; holohedral, Phillips. Observed planes *O*, *I*, 1, 2-2, $\frac{1}{2}$-$\frac{1}{2}$. Figs. 55, 57, 58, and 18 with planes of 55. Cleavage: dodecahedral imperfect. Twins as in tetrahedrite. Massive forms unknown.

H.=3·5—4. G.=4·37—4·53; 4·37—4·49, Cornwall; 4·53, Skutterud. Lustre metallic. Color blackish lead-gray to iron-black. Streak dark reddish-gray. Fracture uneven.

Comp.—$4\ (\mathrm{Ȼu},\ \mathrm{Fe})\ \mathrm{S}+\mathrm{As}^2\ \mathrm{S}^3$, agreeing in crystalline form and general formula with tetrahedrite. Analyses: 1, Phillips (l. c.); 2, Kudernatsch (Pogg., xxxviii. 397); 3, Wackernagel (Ramm, Min. Ch., 88); 4, Rammelsberg (Min. Ch., 88); 5, Fearnley (Scheerer in Pogg., lxv. 298); 6, Plattner (Pogg., lxvii. 422); 7, Merbach (B. H. Ztg., xxv. 187):

	S	As	Cu	Fe	Zn
1. Trevisane, Cornw.	30·25	12·46	47·70	9·75	——=100·16 Phillips.
2. " "	27·76	19·10	48·94	3·57	—— Ag *tr.*, Si 0·08=99·45 Kud.
3. " "	26·88	20·53	48·68	3·09	——=99·18 Wack.
4. " "	26·61	19·03	51·62	1·95	——=99·21 Ramm.
5. Skutterud, G.=4·53	29·18	19·01[a]	42·60	9·21	——=100 Fearnley.
6. *Kupferblende*	28·11	18·88	41·07	2·22	8·89, Ag, Sb, *tr.*, Pb 0·34=99·51 Pl.
7. *Sandbergerite*	25·12	14·75	41·08	2·38	7·19, Sb 7·19, Pb 2·77=100·48 Merbach.

The Kupferblende *Breith.* (or *zincfahlerz*), from near Freiberg (anal. 6), has part of the iron replaced by zinc. Its streak is brownish or dirty cherry-red; G.=4·2—4·4. The *sandbergerite* (anal. 7), from L. Morococha in Peru, is stated to have cubic cleavage, an iron-black color, and G. =4·369; it is in tetrahedral crystals, having also the planes *i*, 2-2.

Pyr.—In the closed tube gives a sublimate of sulphid of arsenic. In the open tube gives sulphurous fumes, and a sublimate of arsenous acid. B.B. on charcoal fuses with intumescence and emission of arsenic and sulphur fumes to a dark-gray magnetic globule. The roasted mineral gives reactions for copper and iron with the fluxes; with soda on charcoal gives metallic copper, with iron.

Obs.- Formerly found in the Cornish mines, particularly at Wheal Jewel in Gwennap, and Wheal Unity in Gwinear, usually in splendent crystals investing other copper ores; but latterly not met with unless at East Relistian mine. Also at Skutterud in Norway, and in Algeria.

Named after the chemist, Smithson Tennant.

128. MENEGHINITE. *Bechi*, Am. J. Sci., II. xiv. 60, 1852.

Monoclinic, v. Rath. Observed planes: vertical, *i-ì*, *i-i*, *I*, *i-⅘*, *i-2*, *i-⅔*, *i-⅓*, *i-3*; hemidomes 1-*i*, 2-*i*, –1-*i*, –2-*i*; hemioctahedral, 2-2, and four others. *I* ∧ *I*=140° 16′, *i-2* ∧ *i-2*, front, 108° 17′, *i-3* ∧ *i-3*, front, 85° 23′, *i-i* ∧ –1-*i* =110° 0′, *i-i* ∧ –2-*i*=124° 30′, *i-i* ∧ 1-*i*=107° 54′, *i-i* ∧ 2-*i*=124° 29′. Crystals slender prismatic. Twins: composition-face *i-i*; 1-*i* ∧ –1-*i*=177° 54′, the two faces 1-*i*, –1-*i* being nearly in the same plane. Also compact fibrous.

H.=2·5. G.=6·339. Lustre metallic, very bright. Resembles boulangerite.

Comp.—4 Pb S+Sb² S³. analogous to tetrahedrite. Analysis: 1, E. Bechi (l. c.); 2, v. Rath (Pogg., cxxxii. 1867):

	S	Sb	Pb	Cu	Fe
1. Bottino	17·52	19·28	59·21	3·54	0·35=99·90 Bechi.
2. "	16·97	18·87	61·47	0·39	0·23, *undec.* 0·82=98·25 Rath.

Obs.—Occurs at Bottino, near Serravezza, in Tuscany, along with galenite, boulangerite, jamesonite, etc., and also crystals of albite; also in the neighboring valley of Castello. First observed by Prof. Meneghini, of Pisa. The crystallization has been determined as above given, and crystals, both simple and compound, figured by v. Rath (l. c.). Q. Sella made it orthorhombic (Gazz. uffic. d'Ital., 1862).

129. GEOCRONITE. Geokronit *Svanberg*, Jahresb., xx. 203, 1839. Kilbrickenite *Apjohn*, Trans. R. Irish Ac., 1840. Schulzit *Hausm.*, Handb., 166, 1847.

Orthorhomic. *I* ∧ *I*=119° 44′, Kerndt. Observed planes: *I*, *i-ĭ*, 1-ĭ. 1-ĭ ∧ 1-ĭ, pyram., about 153° and 64° 45′, bas., 122°. Cleavage: *I*. Usually massive. Also granular or earthy.

H.=2–3. G.=6·4–6·6. Lustre metallic. Color and streak light lead-gray—grayish blue. Fracture uneven.

Comp.—5 Pb S+(Sb, As)² S³=Sulphur 16·5, antimony 16·7, lead 66·8=100. Analyses: 1, Svanberg (Jahresb., xx. 203); 2, Sauvage (Ann. de M., III. xvii. 525); 3, Kerndt (Pogg., lxv. 302); 4, Apjohn (l. c.); 5, Svanberg (Œfv. Ak. Stockh., 1848, 64):

		S	Sb	As	Pb	Cu	Fe

Svanberg deduces for the last the formula 6 Pb S+(Sb, As)² S³.

Pyr.—Same as for zinkenite.

Obs.—From the silver mines of Sala in Sweden; also from Gallicia, Merido in Spain, in nodules in galena; it crumbles easily and soils the fingers; the valley di Castello near Pietro Santo, in Tuscany.

The *kilbrickenite* is from Kilbricken, Clare Co., Ireland.

The name geocronite is derived from γῆ, *earth*, and Κρόνος, *Saturn*, the alchemistic name for lead.

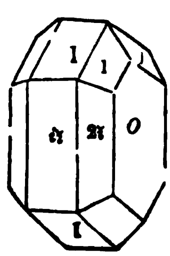
A mineral found at Tinder's gold mine, Louisa Co., Va., may be this species. It contains, according to Genth (Am. J. Sci., II. xix. 19) S 16, Pb 60, Ag 0·25, with antimony and arsenic.

An antimonial ore from between La Paz and Yungas, in Bolivia, is referred here by D. Forbes (Phil. Mag., IV. xxix. 9).

130. STEPHANITE. Argentum rude nigrum ?, *Germ.* Schwarzerz, pt., *Agric.*, Interpr., 462, 1456. Svartgylden, Schvartsertz, pt. Minera argenti nigra spongiosa (fr. Freiberg) *Wall.*, 313, 1747. Stephanit *Haid.*, Handb., 570, 1845.

Orthorhombic. $I \wedge I = 115° \; 39'$, $O \wedge 1\text{-}\bar{i} = 132° \; 32\frac{1}{2}'$; $a : b : c = 1·0897 : 1 : 1·5844$. Observed planes: O; vertical, $i\text{-}\breve{i}$, $i\text{-}\bar{i}$, $i\text{-}\breve{11}$, $i\text{-}\breve{9}$, $i\text{-}\breve{3}$, $i\text{-}\bar{3}$; domes $\frac{2}{3}\text{-}\breve{i}$, $1\text{-}\breve{i}$, $2\text{-}\breve{i}$, $4\text{-}\breve{i}$, $\frac{16}{3}\text{-}\breve{i}$, $7\text{-}\breve{i}$, $8\text{-}\breve{i}$, $1\text{-}\bar{i}$; octahedral, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, $\frac{2}{3}$, 1, 2, $\frac{22}{7}\text{-}\breve{11}$, $3\text{-}\breve{\ }$, $\frac{7}{2}\text{-}\breve{7}$, $1\text{-}\breve{5}$, $\frac{5}{3}\text{-}\breve{5}$, $15\text{-}\breve{5}$, $8\text{-}\breve{4}$, $\frac{3}{4}\text{-}\breve{3}$, $1\text{-}\breve{3}$, $\frac{4}{3}\text{-}\breve{3}$, $3\text{-}\breve{3}$, $\frac{4}{3}\text{-}\breve{2}$, $4\text{-}\breve{2}$, $\frac{12}{5}\text{-}\breve{\frac{12}{7}}$, $5\text{-}\breve{\frac{5}{3}}$, $\frac{5}{2}\text{-}\breve{\frac{5}{3}}$, $6\text{-}\breve{\frac{3}{2}}$; $\frac{3}{2}\text{-}\bar{3}$, $3\text{-}\bar{3}$.

120



$O \wedge \frac{1}{2} = 147° \; 14'$.
$O \wedge 1 = 127 \; 51$.
$O \wedge 2 = 111 \; 14$.
$O \wedge 1\text{-}\breve{i} = 145 \; 34$.
$O \wedge 2\text{-}\breve{i} = 126 \; 6$.

$1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, ov. $i\text{-}\breve{i}$, $= 68° \; 52'$.
$2\text{-}\breve{i} \wedge 2\text{-}\breve{i}$, ov. $i\text{-}\breve{i}$, $= 107 \; 48$.
$1 \wedge 1$, mac., $= 131 \; 16$.
$1 \wedge 1$, brach., $= 96 \; 8$.

Cleavage: $2\text{-}\breve{i}$ and $i\text{-}\breve{i}$ imperfect. Twins: composition-face I; forms like those of aragonite frequent. Also massive, compact, and disseminated.

H.=2–2·5. G.=6·269, Przibram. Lustre metallic. Color and streak iron-black. Fracture uneven.

Comp.—$5 \, Ag \, S + Sb^2 S^3$=Sulphur 16·2, antimony 15·3, silver 68·5=100. **Analyses**: 1, H. Rose (Pogg., xv. 474); Kerl (B. H. Ztg., 1853, No. 2):

	S	Sb	Ag	Fe	Cu
1. Schemnitz	16·42	14·68	68·54	—	0·64=100·28 Rose.
2. Andreasberg	16·51	15·79	68·38	0·14	—=100·82 Kerl.

Considered an arsenical mineral until Klaproth's analysis in 1793 (Beitr., i. 162).

Pyr.—In the closed tube decrepitates, fuses, and after long heating gives a faint sublimate of sulphid of antimony. In the open tube fuses, giving off antimonial fumes and sulphurous acid. B.B. on charcoal fuses with projection of small particles, coats the coal with antimonous acid, which after long blowing is colored red from oxydized silver, and a globule of metallic silver is obtained.

Soluble in dilute heated nitric acid, sulphur and oxyd of antimony being deposited.

Obs.—In veins, with other silver ores, at Freiberg, Schneeberg, and Johanngeorgenstadt in Saxony; at Przibram and Ratieborzitz in Bohemia; at Schemnitz and Kremnitz in Hungary; at Andreasberg in the Harz; at Zacatecas in Mexico; and in Peru.

In Nevada, an abundant silver ore in the Comstock lode; at Ophir and Mexican mines in fine crystals; in the Reese river and Humboldt and other regions. In Idaho, at the silver mines

Named after the Archduke Stephan, Mining Director of Austria. A valuable ore of silver.

The species is homœomorphous with aragonite. See on cryst., F. H. Schroeder, Pogg., xcv. 257

Alt.—Crystals occur altered to silver, and also to argentopyrite (p. 89).

131. **POLYBASITE.** Sprödglaserz pt. *Wern.* Polybasit *H. Rose*, Pogg., xv. 573, 1829. Eugenglanz *Breith.*, Char., 266, 1832.

Orthorhombic, Descl. $I \wedge I$ nearly 120°, $O \wedge 1 = 121° 30'$. Observed planes O, I, 1. $1 \wedge 1$, pyr., $= 129° 32'$, $1 \wedge 1$, bas., $= 117°$. Crystals usually short tabular prisms, with the bases triangularly striated parallel to alternate edges. Cleavage: basal imperfect. Also massive and disseminated. H.=2–3. G.=6·214. Lustre metallic. Color iron-black; in thin crystals cherry-red by transmitted light. Streak iron-black. Opaque except when quite thin. Fracture uneven.

Comp.—9 (Ag, Ɵu) S+(Sb, As)^2 S^3=, if containing silver without copper or arsenic, Sulphur 14·8, antimony 9·7, silver 75·5=100. More probably 10 (Ag, Ɵu) S+(Sb, As)^2 S^3, in which the second member is *half* what it is in the preceding species, and the at. ratio (Ag, Ɵu) and (S, Sb, As) is 2 : 3. Analyses: 1–3, H. Rose (l. c.); 4, C. A. Joy (Inaug. Diss., 24); 5, Tonner (Lotos, 1859, 85, Jahrb. Min., 1860, 716):

	S	Sb	As	Ag	Cu	Fe	Zn	
1. Durango, Mexico	17·04	5·09	3·74	64 29	9·93	0·06	——	=100·15 Rose.
2. Schemnitz	16·83	0·25	6·23	72·43	3·04	0·33	0·59	=99·70 Rose.
3 Freiberg	16·35	8·39	1·17	69·99	4·11	0·29	——	=100·30 Rose.
4. Cornwall	15·87	5·46	3·41	72·01	3·36	0·34	——	=100·45 Joy.
5. Przibram, G.=6·03	15·55	11·53	——	68·55	3·36	0·14	——	=99·13 Tonner.

D. Forbes found in crystallized specimens from Tres Puntos, Chili, 67·47 and 66·94 p. c. of silver. and in a massive ore from Romero, S. of Copiapo, 66·14 p. c. (Private communication.)

Pyr., etc.—In the open tube fuses, gives sulphurous acid and antimonial fumes, the latter forming a white sublimate, sometimes mixed with crystalline arsenous acid. B.B. fuses with spirting to a globule, gives off sulphur (sometimes arsenic), and coats the coal with antimonous acid; with long-continued blowing some varieties give a faint yellowish-white coating of oxyd of zinc, and a metallic globule, which with salt of phosphorus reacts for copper, and cupelled with lead gives pure silver.

Decomposed by nitric acid.

Obs.—Occurs in the mines of Guanaxuato and Gaudalupe y Calvo in Mexico; also at Guarisamez in Durango, with chalcopyrite and calcite; at Tres Puntos, desert of Atacama, Chili: at Freiberg and Przibram. In Nevada, at the Reese mines; in Idaho, at the silver mines of the Owhyhee district.

Named from πολύς, *many*, and βάσις, *base*, in allusion to the many metallic bases present.

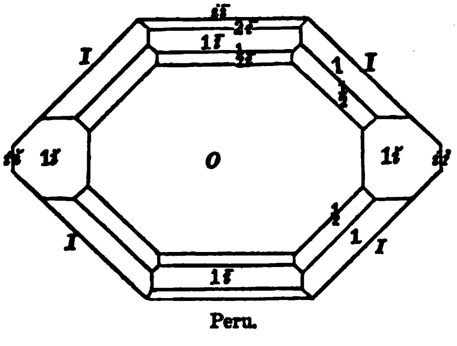
Alt.—Stephanite and pyrite occur as pseudomorphs after polybasite.

132. **ENARGITE.** Enargit *Breith.*, Pogg., lxxx. 383, 1850. Guayacanite *Field*, Am. J. Sci., II. xxvii. 52, 1859.

Orthorhombic. $I \wedge I = 97° 53'$, $O \wedge 1\text{-}\bar{i} = 136° 37'$, Dauber; $a : b : c = 0{\cdot}94510 : 1 : 1{\cdot}1480$. Observed planes: O; vertical, I; $i\text{-}\bar{i}$, $i\text{-}\breve{i}$; domes, $\frac{1}{2}\text{-}\bar{i}$, $1\text{-}\bar{i}$, $2\text{-}\bar{i}$, $1\text{-}\breve{i}$; octahedral, $\frac{1}{2}$, 1.

$$O \wedge \tfrac{1}{2}\text{-}\bar{i} = 154° 43'$$
$$O \wedge 2\text{-}\bar{i} = 117\ 53$$
$$O \wedge 1\text{-}\breve{i} = 140\ 20$$
$$O \wedge 1 = 128\ 35$$

121



Peru.

Cleavage: I perfect; $i\text{-}\bar{i}$, $i\text{-}\breve{i}$ distinct; O indistinct. Also massive, granular or columnar. H.=3. G.=4·43–4·45; 4·362, Kenngott. Lustre metallic. Color grayish to iron-black; streak grayish-black, powder having a metallic lustre. Brittle. Fracture uneven.

Comp.—At. ratio for Cu, As, S=3 : 1 : 4; whence 3 Ɵu S+As^2S^5=Sulphur 32·5, arsenic 19·1, copper 48·4=100. Analyses: 1, Plattner (Pogg., lxxx. 383); 2, F. Field (l. c.); 3, v. Kobell (Ber. Ak. Münch., i. 161, 1865): 4, W. J. Taylor (Proc. Ac. Philad., 168, 1857); 5, Genth (Am. J. Sci., II. xxiii. 420); 6, 7, Luthe & Rammelsberg (ZS. G., xviii. 241); 8, B. S. Burton (private contrib.):

	S	As	Sb	Cu	Fe	Ag
1. Peru	32·22	17·60	1·61	47·20	0·57	0·02, Zn 0·23=99·45 Plattner.
2. Chili, *Guay.*	31·82	19·14	——	48·50	*tr.*	*tr.*=99·46 Field.
3. Coquimbo	32·11	18·10	——	48·89	0·47	—— Te 0·05, Zn, Se *tr.*=99·62 Kobell.
4. N. Grenada	34·50	16·31	1·29	46·62	0·27	——=98·99 Taylor.
5. Chesterfield	33·78	15·68	——	50·59	——	——=100 Genth.
6. Cosihuirachi	31·86	17·17	——	50·08	0·09	——=99·20 Luthe.
7. "	32·45	15·88	——	49·21	1·58	——=99·12 Ramm.
8. Colorado (?)	30·95	17·46	1·35	46·64	1·02	—— insol. 1·98=99·40 Burton.

Genth's analysis was made on "too small a quantity for a complete examination."

Pyr.—In the closed tube decrepitates, and gives a sublimate of sulphur; at a higher temperature fuses, and gives a sublimate of sulphid of arsenic. In the open tube, heated gently, the powdered mineral gives off sulphurous and arsenous acids, the latter condensing to a sublimate containing some antimonous acid. B.B. on charcoal fuses, and gives a faint coating of arsenous acid, antimonous acid, and oxyd of zinc; the roasted mineral with the fluxes gives a globule of metallic copper.

Soluble in nitro-muriatic acid.

Obs.—From Morococha, Cordilleras of Peru, at a height of 15,000 feet, in large masses, occasionally with small druses of crystals, along with tennantite, imbedded in crystalline limestone (anal. 1); Cordilleras of Chili (*guayacanite*, anal. 2); same, mine of Hediondas, Prov. Coquimbo (anal. 3); mines of Santa Anna, N. Grenada, in cavities in quartz (anal. 4); at Cosihuirachi in Mexico; Brewster's gold mine, Chesterfield district, S. Carolina (anal. 5); in Colorado (anal. 8); at Willis's Gulch, near Black Hawk.

For Dauber on cryst., see Pogg., xcii. 237. Breithaupt (ib., lxxx. 383) made $I \wedge I$=98° 11′, and Rammelsberg (ZS. G., xviii. 242) 98° 10′.

133. XANTHOCONITE. Xanthokon *Breith.*, J. pr. Ch., xx. 67, 1840.

Rhombohedral; $R \wedge R=71°\ 34'$; $O \wedge R=110°\ 30'$, $a=2·3163$. Observed planes R, −2, O. $O \wedge 2=100°\ 35'$. Cleavage: R, and O. Usually in reniform masses, with the interior consisting of minute crystals.

H.=2. G.=5·0—5·2. Color dull-red to clove-brown; crystals orange-yellow on the edges by transmitted light. Streak-powder yellow. Brittle.

Comp.—(3 Ag S+As^2S^3)+2 (3 Ag S+As^2S^5)=Sulphur 21·1, arsenic 14·9, silver 64·0=100. Analyses: Plattner (Pogg., lxiv. 275):

	S	As	Ag	Fe
1.	21·36	[13·49]	64·18	0·97=100
2.	21·80	[14·32]	63·88	——=100

Pyr.—In the closed tube, at a gentle heat, the yellow color is changed to dark-red, but on cooling it regains its original color; at a higher temperature fuses, and gives a faint sublimate of sulphid of arsenic. In the open tube, and on charcoal, behaves like proustite.

Obs.—Occurs with stephanite at the Himmelsfürst mine near Freiberg.

Named in allusion to its yellow powder, from ξανθός, *yellow*, and κόνις, *powder*.

APPENDIX TO SULPHIDS, ETC.

134. CLAYITE *W. J. Taylor*, Proc. Ac. Philad., Nov. 1859.

Isometric, tetrahedral. Occurring form the tetrahedron, with planes of the dodecahedron. Crystals small. Also massive, incrusting.

H.=2·5. Lustre metallic. Color and streak blackish lead-gray. Opaque. Sectile.

Analyses by W. J. Taylor (l. c.):

	S	As	Sb	Pb	Cu	Ag
1.	8·22	9·78	6·54	68·51	7·67	*trace.*
2.	8·14	*undet.*	*undet.*	67·40	5·62	——

From Peru. Probably a result of alteration. Requires further investigation.

135. BOLIVIANITE. Bolivian *Breith.*, B. H. Ztg., xxv. 188.

Orthorhombic. In acicular rhombic prisms, tufts, and fine columnar. Resembles stibnite. H.=2½. G.=4·820—4·828. Cleavage: *i-ĭ* distinct. Lustre submetallic. Color lead-gray, a little darker than in stibnite.

According to T. Richter, an antimonial sulphid of silver, containing 8·5 p. c. of silver. From Bolivia.

65B. SULPHOSELENID OF ZINC AND MERCURY. *A. del Castillo*, in priv. comm., dated Mexico, Feb. 27, 1865, to Prof. Henry, and from him to the author.

In crystals (rhombohedrons ?); cleavage not observed. H.=3. G.=6·67—7·165. Color dark lead-gray. Streak grayish-black.

Comp.—According to Castillo's trials, a compound of sulphur, selenium, zinc, and mercury, of undetermined proportions.

Pyr. etc.—In the closed tube gives a grayish-black sublimate, and above this a ring of metallic mercury; in the open tube affords the odor of selenium, a blackish zone of selenium, and above this a grayish-red oxyd, and still higher a sublimate of mercury. B.B. the selenium and mercury are volatilized, leaving a residue of oxyd of zinc, yellow while hot and white on cooling. On charcoal burns with a bluish flame, giving first the odor of sulphur and then of selenium; the assay turns yellow, then red, and finally yields a yellow skeleton of oxyd of zinc. Insoluble in nitric acid; soluble in nitro-muriatic acid.

Obs.—Occurs at the quicksilver mines of Guadalcasar, along with cinnabar, and in cavities in barite, fluorite, and gypsum. Appears to be near *onofrite*, No. 65A, p. 56.

III. COMPOUNDS OF CHLORINE, BROMINE. IODINE

154. Percylite.

Appendix.—155. Chlorid of Magnesium. 156. Chlorid of Manganese. 157. Iodid of Zinc 158. Bromid of Zinc.

1. ANHYDROUS CHLORIDS, ETC.

136. **CALOMEL.** Horn Mercury (fr. Deux Ponts) *Woulfe*, Phil. Trans., 618, 1776. Mine de mercure cornée *de Lisle*, Crist., iii. 161, 1783. Quecksilber-Hornerz *Wern.*, Bergm. J., 381, 1789. Horn Quicksilver; Dichlorid of Mercury. Kalomel, Chlorquecksilber, Chlormercur, *Germ.* Mercure chloruré *Fr.*

Tetragonal. $O \wedge 1\text{-}i = 129° \ 4'$; $a = 1{\cdot}232$. Observed planes: vertical, I, $i\text{-}\bar{i}$, $i\text{-}\frac{4}{3}$; octahedral, $\frac{1}{4}$, $\frac{1}{3}$, 1; $\frac{2}{3}\text{-}i$, $2\text{-}i$; zirconoid, 2-2, $2\text{-}\frac{4}{3}$, $\frac{4}{3}\text{-}2$.

$O \wedge 2\text{-}i = 112° \ 5'$	$O \wedge 1 = 119° \ 51'$	$2\text{-}i \wedge 2\text{-}i$, pyr., $= 98° \ 8'$
$O \wedge \frac{2}{3}\text{-}i = 140 \ 36$	$O \wedge \frac{1}{3} = 149 \ 51$	$1 \wedge 1$, pyr., $= 104 \ 20$

Pyramid $2\text{-}i$ when alone gives a very acute termination to the prism. Cleavage: I, indistinct. Twins compounded so as to have the vertical axis in one line, but the edges of the pyramid of one in the same plane with the faces of the pyramid of the other.

H.=1–2. G.=6·482, Haidinger. Lustre adamantine. Color white, yellowish-gray, or ash-gray, also grayish, and yellowish-white, brown. Streak pale yellowish-white. Translucent—subtranslucent. Fracture conchoidal. Sectile.

Comp.—$Hg^2 \, Cl$=Chlorine 15·1, mercury 84·9=100.

Pyr., etc.—In the closed tube volatilizes without fusion, condensing in the cold part of the tube as a white sublimate; with soda gives a sublimate of metallic mercury. B.B. on charcoal volatilizes, coating the coal white. Insoluble in water, but dissolved by nitro-muriatic acid; blackens when treated with alkalies.

Obs.—At Moschellandsberg in the Palatinate, coating the cavities of a ferruginous gangue, associated with cinnabar—crystals often large and well-defined; also at the quicksilver mines of Idria in Carniola; Almaden in Spain; Horzowitz in Bohemia.

According to Hessenberg, crystals from Moschellandsberg afford $O \wedge 1\text{-}i = 129° \ 40'$, $O \wedge 2\text{-}i = 112° \ 35'$.

Named from καλός, *beautiful*, and μέλι, *honey*, the taste being sweet, and the compound the *Mercurius dulcis* of early chemistry.

137. **SYLVITE.** Muriate of Potash (fr. Vesuvius) *Smithson*, Ann. Phil., II. vi. 258, 1823. Chlorid of Potassium. Kali Salzsaures, Chlorkalium, *Germ.* Sylvine *Beud.*, Tr., ii. 511, 1832. Hoevelit *H. Girard*, Jahrb. Min. 1863, 568. Leopoldit *E. Reichardt*, Jahrb. Min. 1866, 331. Schätzellit and Hövellit (fr. Stassfurt), B. H. Ztg., xxiv. 276, Ann. Ch. Phys., IV. v. 318, 324.

Isometric. Figs 1, 6, 2. Cleavage cubic. Also compact.

H.=2. G.=1·9–2. White or colorless. Vitreous. Soluble; taste like that of common salt.

Comp.—$K \, Cl$=Potassium 52·5, chlorine 47·5=100. That of Vesuvius, according to A. Müller (Verh. Ges. Basel, 1854, 113), is pure, affording no trace of lime, magnesia, or alumina, and only a trace of soda. The sylvite of the Anhalt salt mine, Leopoldshall, afforded Reichardt (l. c.) K 52·4, Cl 47·4.

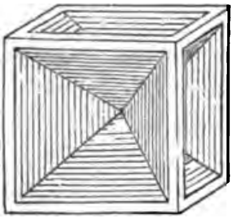
Pyr., etc.—B.B. in the platinum loop fuses, and gives a violet color to the outer flame. Added to a salt of phosphorus bead, which has been previously saturated with oxyd of copper, colors the O.F. deep azure. Water completely dissolves it, 100 parts taking up 34·5 at 18·75° C. Heated with sulphuric acid gives off muriatic acid gas.

Obs.—Occurs at Vesuvius, about the fumaroles of the volcano. Also at Stassfurt, in the carnallite beds of the salt formation; at Leopoldshall (*leopoldite*).

The compound is the *Sal digestivus Sylvii* of early chemistry, whence Beudant's name for the species. There is no reason for changing it in the fact that the earlier known mineral was of volcanic origin.

138. HALITE. COMMON SALT. **Rock Salt, Muriate of Soda, Chlorid of Sodium. Kochsalz, Steinsalz, Bergsalz, *Germ.* Soude muriatée, Chlorure de sodium, Sal gemme, *Fr.* Salmare *Beud.*, Tr., 1832. Halites *Glock.*, Syn., 290, 1847.**

122



Isometric. Observed planes, *O*, 1, *I*, *i*-2. Figs. 1, 2, 6, 16, and 6+16; usually in cubes; rarely in octahedrons; faces of crystals sometimes cavernous, as in f. 122. Cleavage: cubic, perfect. Massive and granular, rarely columnar.

H.=2·5. G.=2·1–2·257; of pure crystals, 2·135, Hunt. Lustre vitreous. Streak white. Color white, also sometimes yellowish, reddish, bluish, purplish; often colorless. Transparent—translucent. Fracture conchoidal. Rather brittle. Soluble; taste purely saline.

Comp.—Na Cl=Chlorine 60·7, sodium 39·3=100. Commonly mixed with some sulphate of lime, chlorid of calcium, and chlorid of magnesium, and sometimes sulphate of magnesia, which render it liable to deliquesce. Analyses: 1–8, Berthier (Ann. d. M., x. 259); 9, Fournet (ib., IV. ix. 551); 10, Rammelsberg (Min. Ch., 1014); 11, 12, C. A. Goessmann (Rep. on Petit Anse Salt Mine, Bureau of Mines, New York, 1867, 17):

Other analyses: Salt from Stassfurt, by Heintz, ZS. nat. Ver. Halle, xi. 345; from Algiers, by de Marigny and Simon, Ann. d. M., xii. 674; from Wieliczka, Berchtesgaden, Hall in the Tyrol, Hallstadt, Schwabisch-Hall, by G. Bischof, Geol., ii. 1669, 1675; from Erfurt and Cardona, by Söchting, ZS. nat. Ver. Halle, vii. 404; from Vesuvius, 1822, by Laugier, Pogg., iii. 79; from Vesuvius, 1850, by Bischof; from Vesuvius, 1850, by Scacchi, Ann. d. M., IV. xvii. 323; from Vesuvius, 1855, by Deville, Bull. G. Fr. II. xiii. 620.

Dissolves in three parts of water. Some varieties attract moisture, but are unchanged in a dry atmosphere.

The *martinsite* of Karsten (J. pr. Ch., xxxvi. 127) contains 9·02 per cent. of sulphate of magnesia, which is equivalent to 10 parts of common salt to 1 of sulphate of magnesia. It is from Stassfurt. In Rammelsberg's analysis the water was hygroscopic, and the specimen contained 0·49 of mixed karstenite. In a dirty reddish salt from Abingdon, Washington Co., Va., E. Stieren found (Jahresb., 1862, 766) NaCl 90·55, gypsum 0·45, clay and carb. lime 9·00=100.

The bluish and indigo-colored salt of Stassfurt, etc., possibly owes its color, according to Prof. S. W. Johnson, to the presence of subchlorid of sodium.

Pyr., etc.—In the closed tube fuses, often with decrepitation; when fused on the platinum loop colors the flame deep yellow. Other reactions like those given under sylvite.

Obs.—Common salt occurs in extensive but irregular beds in rocks of various ages, associated with gypsum, polyhalite, clay, sandstone, and calcite; also dissolved, and forming salt springs.

In Europe and England it occurs in the Triassic, associated with red marl or sandstone, but it is not confined to these rocks. At Durham, Northumberland, and Leicestershire, England, salt springs rise from the Carboniferous series; in the Alps, some salt works are supplied from Oolitic rocks; the famous mines of Cardona and Wieliczka are referred, the former to the Green Sand formation and the latter to Tertiary rocks. Salt springs also occur in volcanic regions. In the United States the brines of New York come from Upper Silurian strata; those of Ohio, Pennsylvania, and Virginia, mostly from Devonian and Subcarboniferous beds; those of Michigan, mainly from the Subcarboniferous and Carboniferous; while in Louisiana, at Petit Anse, there is a thick bed of pure salt in the Post-tertiary or more recent deposits of the coast; recent explorations there have proved that it underlies 144 acres, and it has been penetrated to a depth of 38 feet without showing any change in its structure or purity. Salt also occurs as efflorescences over the dry prairies and shallow ponds or lakes of the Rocky Mountains, California, Atacama; and in most desert or semi-desert regions there are numerous salt lakes.

The principal mines of Europe are at Wieliczka, in Poland; at Hall, in the Tyrol; Stassfurt, in Prussian Saxony; and along the range through Reichenthal in Bavaria, Hallein in Salzburg, Hallstadt, Ischl, and Ebensee, in Upper Austria, and Aussee in Styria; in Hungary, at Marmoros and elsewhere; in Transylvania; Wallachia, Gallicia, and Upper Silesia; Vic and Dieuze in France; Valley of Cardona and elsewhere in Spain, forming hills 300 to 400 feet high; Bex in Switzerland; and Northwich in Cheshire, England. At Cheshire it occurs in a basin-shaped deposit, and is arranged in spheroidal masses, from 5 to 8 feet in diameter, which are composed of concentric coats, and present polygonal figures. It is but little contaminated with impurities, and is prepared for use by merely crushing it between iron rollers. At the Austrian mines, where it contains much clay, the salt is dissolved in large chambers, and the clay thus precipitated. After a time the water, fully saturated with the salt, is conveyed by aqueducts to evaporating houses, and the chambers, after being cleared out, are again filled; at Berchtesgaden, the water is saturated in a month, at Hall it takes nearly a year.

It also occurs, forming hills and covering extended plains, near Lake Oroomiah, the Caspian Lake, etc. In Algeria; in Abyssinia; in India in the province of Lahore, and in the valley of Cashmere; in China and Asiatic Russia; in South America, in Peru, and at Zipaquera and Nemocon, the former a large mine long explored in the Cordilleras of Granada. Occasionally formed at the eruptions of Vesuvius, as in 1855, when it was found in cubes, incrustations, and stalactites.

In the United States, salt has been found forming beds with gypsum, in Virginia, Washington Co., 18 m. from Abingdon; in the Salmon River Mts. of Oregon; in Louisiana, as already mentioned. Brine springs are very numerous in the Middle and Western States. These springs are worked at Salina and Syracuse, N. Y.; in the Kanawha Valley, Va.; Muskingum, Ohio; Michigan, at Saginaw and elsewhere; and in Kentucky. The salt water is obtained by boring, and raised by means of machinery, and thence conveyed by troughs to the boilers, where it is evaporated by artificial heat; or to basins for evaporation by exposure to the heat of the sun.

The following table by Prof. Beck (Mineralogy of New York, p. 112), gives the amount of brine required for a bushel of salt at the principal salt springs in the United States:

	Galls.		Galls.
Boone's Lick, Missouri	450	Kanawha, Va.	75
Conemaugh, Penn.	300	Grand River, Ark.	80
Shawneetown, Ill.	280	Illinois River, Ark.	80
Jackson, Ohio	213	Montezuma, N. Y.	70
Lockhart's, Miss.	180	Grand Rapids, Mich.	50–60
St. Catherines, Upper Canada	120	Muskingum, Ohio	50
Zanesville, Ohio	95	Salina—Old wells	40–45
		New wells	30–35

Sea water at Nantucket gives a bushel of salt for every 350 gallons.

Composition of Syracuse brines, according to analyses by Dr. C. A. Goessmann (private communication):

	I.	II.	III.	IV.
Chlorid of sodium	16·7503	15·5317	18·2465	13·3767
Sulphate of lime	0·5673	0·5772	0·5117	0·5234
Chlorid of calcium	0·1594	0·1533	0·1984	0·1037
Chlorid of magnesium	0·1464	0·1444	0·1784	0·1336
Bromid of magnesium	0·0022	0·0024	0·0025	0·0017
Chlorid of potassium	0·0110	0·0109	0·0119	0·0086
Carbonate of protoxyd of iron	0·0034	0·0044	0·0036	0·0015
Water	82·3600	83·5757	80·8470	85·8508
	100	100	100	100

No. I. has G.=1·1300 at 16° Baumé, and 20° C. No. II. has G.=1·1225 at 15° Baumé, and 21° C. The Saginaw brines, Michigan, afford about 19·250 of salt.

Vast lakes of salt water exist in many parts of the world. Lake Timpanogos in the Rocky mountains, 4,200 feet above the level of the sea, now called the Great Salt Lake, is 2,000 square miles in area. L. Gale found in this water 20·196 per cent. of chlorid of sodium (Stansb. Exped. cited in Am. J. Sci., II. xvii. 129). The Dead and Caspian Seas are salt, and the waters of the former contain 20 to 26 parts of solid matter in 100 parts. Prof. Gmelin, who analyzed a portion of these waters of specific gravity 1·212, found them to contain chlorid of calcium 3·336, chlorid of magnesium 12·167, chlorid of sodium 7·039, sulphate of lime 0·052, bromid of magnesium 0·443, chlorid of potassium 1·086, chlorid of aluminum 0·144, chlorid of ammonium 0·007, chlorid of manganese 0·161=24·435, with 75·565 water=100·000. This result is given as corrected by Marchand.

Alt.—Anhydrite, gypsum, polyhalite, occur as pseudomorphs after this species; also celestine, dolomite, quartz, hematite, pyrite; the removal of the salt cubes by their solution, leaves a cavity which any mineral may then occupy. The hopper-shaped crystals often leave an impression of their form on clays.

139. SAL AMMONIAC. Naturliches Salmiak (fr. Bucharia) *J. G. Model*, Versuch über ein nat. Salmiak, Leipzig, 1758. Muriate of Ammonia; Chlorid of Ammonium. Salmiak *Germ.* Ammoniaque muriatée *Fr.* Salmiac *Beud.*, Tr., 1832.

Isometric. Observed planes, *O*, 1, *I*, 2-2. Figs. 1, 2, 3, 6, 10, 14. Cleavage octahedral. Also stalactitic, and in globular masses; in crusts, or as an efflorescence.

H.=1·5—2. G.=1·528. Lustre vitreous. Color white; often yellowish or grayish. Streak white. Translucent—opaque. Fracture conchoidal. Soluble; taste saline and pungent; not deliquescent.

Comp.—NH^4Cl=Am Cl=Ammonium 33·7, chlorine 66·3=100. Klaproth obtained (Beitr., iii. 89):

	Vesuvius.	Bucharia.
Chlorid of ammonium	99·5	97·50
Sulphate of ammonia	0·5	2·50

B. Silliman, Jr., obtained (Dana's G. Rep. Expl. Exp., 202) for a specimen from Kilauea, Hawaii, Chlorid of ammonium 65·53, chlorid of iron 12·14, sesquioxyd of iron 8·10, chlorid of aluminum 13·00, insoluble matter and loss 1·23=100. For an analysis of an impure Stromboli specimen, see C. Schmidt, in ZS. G., ix. 403.

Pyr., etc.—Sublimes in the closed tube without fusion. Pulverized with hydrate of lime, or heated with a solution of caustic alkali, gives off pungent ammoniacal vapors. Soluble in three times its weight of water.

Obs.—Occurs about volcanoes, as at Etna, the island of Vulcano, Vesuvius, Stromboli, Sandwich Islands, and near Hecla after the eruption of 1845, as observed by Bunsen. Observed after the eruption of Vesuvius in 1855, in rhombic dodecahedrons with cavernous faces; and as usual it occurred where the lavas had spread over soil and vegetation. Also found in small quantities in the vicinity of ignited coal seams, as at St. Etienne in France, and also at Newcastle, and in Scotland; crystallized near Duttweiler in Prussia, where a coal seam has been burning for more than a hundred years. It occurs also in Bucharia; at Kilauea in Hawaii, a variety which contains largely of iron (see above), and becomes rusty yellow on exposure; in guano from the Chincha Islands.

The ἅλς ἀμμωνιακός, sal-ammoniac of Dioscorides, Celsius, and Pliny, is proved by Beckmann (Hist. of Inventions, iv. 360) to be common rock salt, dug in Egypt, near the oracle of Ammon. The name was afterward transferred to the muriate of ammonia, when subsequently manufactured in Egypt. Sal-ammoniac is supposed to have been included by the ancients, with one or two other species, under the name of *nitrum*, which, according to Pliny, gave the test of ammonia when mingled with quicklime.

140. CERARGYRITE. Argentum cornu pellucido simile (fr. Marienberg), *Germ.* Hornfarbe-Silber, *Gesner*, Foss., 63, 1565. Argentum rude jecoris colore, lucem corneam habens (fr. Freiberg, etc.) *G. Fabricius*, De Rebus Met., 1566. Glaserz, durchsichtig wie ein Horn in einer Lantern, *Matthesius*, Sarept., 1585. Horn-Silfver, Minera argenti cornea, A. sulphure et arsenico mineralisatum, *Wall.*, 310, 1747. Argento acido salis mineralisatum, Hornerz, *Cronst.*, 159, 1758

Silberhornerz, Silberkerat, Hornsilber, Chlor-Silber, *Germ.* Horn Silver; Corneous Silver Argent muriaté, Argent corné, Chlorure d'argent *Fr.* Buttermilcherz (first mentioned early in 17th century). Kerargyre *Beud.*, Tr., ii. 501, 1832. Kerat *Haid.*, Handb., 506, 1845. Argyroceratite *Glock.*, Syn., 249, 1847. Plata cornea blanca *Domeyko*, Min., 200, 1845. Kerargyrite

Isometric. Observed forms, *O*, *I*, 1, 2, 2-2; f. 1, 2, 3, 5, 6, 7; also 5 with planes 1, 2, 2-2. Cleavage none. Twins: composition-face octahedral. Usually massive and looking like wax; sometimes columnar, or bent columnar; often in crusts.

H.=1—1·5. G.=5·552; 5·31—5·43, Domeyko. Lustre resinous, passing into adamantine. Color pearl-gray, grayish-green, whitish, rarely violet-blue, colorless sometimes when perfectly pure; brown or violet-brown on exposure. Streak shining. Transparent—feebly subtranslucent. Fracture somewhat conchoidal. Sectile.

Comp.—Ag Cl=Chlorine 24·7, silver 75·3=100. This constitution corresponds with Klaproth's analyses (Beitr., i. 134, and iv. 10); also F. Field's of a specimen from Chañarcillo, Chili (Q. J. Ch. Soc., x. 239).

Pyr., etc.—In the closed tube fuses without decomposition. B.B. on charcoal gives a globule of metallic silver. Added to a bead of salt of phosphorus, previously saturated with oxyd of copper, and heated in O.F., imparts an intense azure-blue to the flame. A fragment placed on a strip of zinc, and moistened with a drop of water, swells up, turns black, and finally is entirely reduced to metallic silver, which shows the metallic lustre on being pressed with the point of a knife. Insoluble in nitric acid, but soluble in ammonia.

Obs.—Occurs in veins of clay slate, accompanying other ores of silver, and usually only in the higher parts of these veins. It has also been observed with ochreous varieties of brown iron ore; also with several copper ores, calcite, barite, etc.

The largest masses, and particularly those of a green color, are brought from Peru, Chili, and Mexico, where it occurs with native silver. In Chili, at some mines, it is a much less common ore than the chlorobromid; often contains, intimately mixed with it, native silver in very minute grains; it occurs at Tres Puntos, Atacama, Chañarcillo near Copiapo, and elsewhere in Chili. Also in Nicaragua near Ocotal; in Dept. of Gracias, Honduras. It was formerly obtained in the Saxon mining districts of Johanngeorgenstadt and Freiberg, but is now rare; a mass weighing six and three-quarter pounds, from this region, is in the Zwinger collection at Dresden. It also occurs in the Altai, at the mines of Smeinogorsk and Krukovskoi; at Konigsberg in Norway; in Alsace; rarely in Cornwall, and at Huelgoet in Brittany. In Nevada, about Austin, Lander Co., abundant; at mines of Comstock lode. In Arizona, in the Willow Springs dist., veins of El Dorado cañon, and San Francisco dist. In Idaho, at the Poorman mine, in crystals some half an inch across, mostly cubes and cubo-octahedrons, but occasionally with other planes, and in twins consisting of two interpenetrating cubes, the angles of one projecting from the faces of the other.

At Andreasberg in the Harz, an earthy variety is met with, called by the Germans Buttermilk ore (*Buttermilcherz*, *Thonige Hornsilber*), which, according to Klaproth (Beitr., i. 187), contains silver 24·64, chlorine 8·28, alumina 67·08. Funckens describes it as "weiss und dünn wie einé Buttermilch" (Lenz Min., ii. 101, 1794).

Named from κέρας, *horn*, and ἄργυρος, *silver*—*Ceratargyrite*, the proper derivative, being contracted to *Cerargyrite*. The Greek *k* becomes *c*, as in other cases.

141. **EMBOLITE.** Chlorobromure d'argent *Domeyko*, Ann. d. M., IV. vi. 153, 1844; Berthier, ib., IV. ii. 540, 1842. Plata cornea verde *Domeyko*, Min., 202, 1845. Embolit *Breith.*, Pogg., lxxvii. 134, 1849. Chlorobromid of Silver. Chlorbromsilber. Megabromite, Microbromit, *Breith.*, B. H. Ztg., xviii. 449, 1859.

Isometric. Figs. 1, 4, 6, 7, 6+7, 11. Also massive; sometimes stalactitic or concretionary at surface.

H.=1—1·5. G.=5·31—5·43, Domeyko: 5·53, Yorke; 5·79—5·81, Breith. Lustre resinous and somewhat adamantine. Color grayish-green and asparagus-green to pistachio or yellowish-green, and yellow, often dark; becoming darker externally on exposure.

Comp.—Ag (Cl, Br). the ratio of the chlorine to the bromine varying indefinitely, the yellowish varieties and those of deeper green colors containing the largest proportion of bromine. **Analyses:** 1, 2, Domeyko (Min., 1845, 203, and 1860, 212); 3, Müller (B. H. Ztg., xviii. 449); 4, 5, Domeyko (l. c.); 6, 7, F. Field (Q. J. Ch. Soc., x. 239); 8, Yorke (Q. J. Ch. Soc., iv. 149); 9, Plattner (Pogg., lxxvii. 134); 10, 11, Domeyko (l. c.); 12, Richter (B. H. Ztg., xviii. 449); 13, F. Field (l. c.); arranged in the order of the proportion of bromid to chlorid (mentioned in column Br : Cl), commencing with those having the least of the bromid:

	Ag	Br	Cl	Br : Cl	
1. Chañarcillo, *pearly green*	71·94	7·92	20·14	1 : 5·67	Domeyko.
2. " " "	70·44	11·53	18·03	1 : 3·5	"
3. Copiapo, *microbromite*	69·84	12·39	17·77	1 : 3	Müller.
4. Quillota, *pearly green*	69·28	14·30	16·42	1 : 2·75	Domeyko
5. Chañarcillo " "	69·14	14·63	16·23	1 : 2·5	"
6. " *light geeen*	68·22	16·84	14·92	1 : 2	Field.
7. " *embolite*	66·94	19·82	13·18	1 : 1·5	"
8. Chili, *Greenish yellow*	66·95	19·90	13·15	1 : 1·5	Yorke.
9. Chañarcillo, *embolite*	66·86	20·08	13·05	———	Plattner.
10. " "	66·84	20.09	13·07	1 : 1·5	Domeyko.
11. " *yellow*	66·53	20·85	12·62	1 : 1·33	"
12. *Megabromite*	64·19	26·49	9·32	1 : 0·8	Richter.
13. Chañarcillo, *dark green.*	61·07	33·82	5·00	1 : 0·33	Field.

The *megabromite* and *microbromite* of Breithaupt are only varieties of embolite based on the proportion of bromid to chlorid, and are even indistinct as varieties, these extremes being connected by indefinite shadings. The above numbers for Domeyko's and Yorke's analyses are calculated from their statements of the proportion of chlorid and bromid, which they give as follows:

	1	2	4	5	8	10	11
Chlorid of silver	81·4	72·9	66·4	65·6	53·2	52·8	51·0
Bromid of silver	18·6 D.	27·1 D.	33·6 D.	34·4 D.	46·8 Y.	47·2 D.	49·0

Obs.—Abundant in Chili, constituting the principal silver ore of the mines of Chañarcillo, and found also at Agua-Amarga, Tres-Puntas, Rosilla, and at all the new openings in the province of Copiapo; found also at Eulalia in Chihuahua, Mexico; at the mine of Coloal in Gracias, Honduras.

Named from ἐμβόλιον, *an intermediate*, because between the chlorid and bromid of silver.

142. BROMYRITE. Bromure d'Argent, Plata Verde *Mex.*, (fr. Mexico and Huelgoet), *Berth.*, Ann. d. M., III. xix. 734, 742, 1841, IV. ii. 526. Bromid of Silver; Bromic Silver. Bromsilber *Germ.* Bromit *Haid.*, Handb., 506, 1845. Bromyrite *Dana*, Min., 93, 1854. Bromargyrit *Ramm.*, Min. Ch., 196, 1860. Plata cornea amarilla melada *Domeyko*, Min., 214, 1860.

Isometric. Figs. 1, 2, 4, 6. Occurs usually in small concretions; rarely in crystals.

H.=2–3. G.=5·8–6. Lustre splendent. Color when pure bright-yellow to amber-colored, slightly greenish; often grass-green or olive-green externally. Little altered in color on exposure. Sectile.

Comp.—Ag Br=Bromine 42·6, silver 57·4=100. **Analyses:** 1, Berthier (Ann. d. M., IV. ii 526); 2, F. Field (Q. J. Ch. Soc., x. 241):

1. Mexico	Bromine 42·44	Silver 57·56=100	Berthier.
2. Chañarcillo	42·57	57·43=100	Field.

In the Chilian ore Domeyko found 57·1 of silver.

Pyr., etc.—In the closed tube and with metallic zinc reacts like cerargyrite. B.B. on charcoal emits pungent bromine vapors and yields a globule of metallic silver. Fused with bi-sulphate of potash in a matrass gives off yellowish-brown vapors of bromine. Insoluble in nitric acid. Difficultly soluble in ammonia.

Obs.—With other silver ores in the district of Plateros, Mexico, and at the mine of San Onofre, seventeen leagues from Zacatecas, associated with chlorid of silver and carbonate of lead; also in crystals at Chañarcillo, Chili, with chlorid of silver, sometimes imbedded in calcite; also at Huelgoet in Brittany, with cerargyrite.

143. IODYRITE. Iodure d'Argent *Vauquelin*, Ann. Ch. Phys., xxix. 99, 1825; *Domeyko*, Ann. d. M., IV. vi. 158, 1844. Plata cornea amarilla *Domeyko*, Min., 205, 1845. Iodic Silver. Iodsilber *Germ.* Iodit *Haid.*, Handb., 506, 1845. Iodyrite *Dana*, Min., 95, 1854. Iodargyrit *Ramm.*, Min. Ch., 197, 1860.

Hexagonal. $O \wedge 1=136^\circ\ 46'$; $a=0{\cdot}81438$. Observed planes: O, I, 4, 2, ½. Angles:

$O\wedge 2=118^\circ$	$O\wedge \frac{1}{2}=154^\circ\ 49'$	$2\wedge 2$, pyr., $=127^\circ\ 36'$
$O\wedge 4=104\ \ 53'$	$\frac{1}{2}\wedge\frac{1}{2}$, pyr., $=155\ \ 26$	$4\wedge 4$ " $=122\ \ 12$

Cleavage: basal perfect. Also massive, and in thin plates with a lamellar structure.

Soft. G.=5·5—5·71; 5·707, Damour; 5·504, Domeyko; 5·64—5·67, Breith. Lustre resinous to adamantine. Color citron and sulphur-yellow to yellowish-green, sometimes brownish. Streak yellow. Translucent. Plates flexible, sectile.

Comp.—$\mathrm{Ag}\,\dot{\mathrm{I}}$=Iodine 54, silver 46=100. Analyses: 1, Domeyko (l. c.); 5, Damour (Ann. d. M., V. iv. 329); 3, 4, J. L. Smith (Am. J. Sci., II. xviii. 374); 5, F. Field (J. Ch. Soc., x. 241):

		Ag	I
1. Algodones		46·25	[53·75]=100 Domeyko.
2. "	(½)	45·72	54·03=99·75 Damour.
3. "		46·52	52·93=99·45[a] Smith.
4. "		46·38	53·11=99·49[a] Smith.
5. Chañarcillo		45·98	54·02=100 Field.

[a] With traces of chlorine and copper.

Pyr., etc.—In the closed tube fuses and assumes a deep orange color, but resumes its yellow color on cooling. B.B. on charcoal gives fumes of iodine and a globule of metallic silver. With zinc reacts like cerargyrite and bromyrite. Fused with bisulphate of potash in a matrass, yields violet vapors of iodine.

Obs.—Occurs in thin veins or seams in hornstone at Albarradon, near Mazapil; in Mexico; at Algodones, 12 leagues from Coquimbo; less abundantly at Delirio mines of Chañarcillo, Chili, where the crystals are sometimes half an inch broad (Breith., B. H. Ztg., xviii. 450); also at Guadalajara in Spain. In Arizona at Cerro Colorado mine. Descloizeaux has pointed out its homœomorphism with greenockite (Ann. Ch. Phys., III. xl.).

144. COCCINITE. Iodure de Mercure *Del Rio*; *Beud.*, Tr., ii. 515, 1832. Coccinit *Haid.*, Handb., 572, 1845. Mercure ioduré *Fr.* Iodquecksilber *Germ.*

In particles of a reddish-brown color on selenid of mercury, adamantine in lustre, at Casas Viejas, Mexico; and supposed by Del Rio to be an iodid of mercury. But Castillo says (Colegio de Min. Mexico, 1865) that specimens labelled by Del Rio contain no iodine, and appear to be largely chlorine and mercury, yet are not calomel. Castillo describes it from Zimapan and Culebras, both massive and in acute, acicular, rhombic pyramids, 2–6 mm. long; color fine red to yellow, and sometimes yellowish-green, changing to greenish-gray and dark green on exposure; transparent to translucent. In a closed tube affords a sublimate, white when cold, of $\mathrm{Hg}^2\mathrm{Cl}$, and leaves a residuum which is dull red while hot, orange-yellow when cold, and which B.B. turns aurora-red, and is dissipated with an odor like that of selenium.

145. COTUNNITE. Cotunnia *Mont. & Cov.*, Prodr. Oritt. Vesuv. Cotunnite. Chlorid of Lead.

Orthorhombic. $I\wedge I=99^\circ\ 46'$, $O\wedge 1\text{-}\bar{i}=149^\circ\ 14'$; $a:b:c=0{\cdot}5953:1:1{\cdot}1868$. Observed planes: I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}2$, $1\text{-}\breve{i}$. $O\wedge 1=142^\circ\ 6'$, $O\wedge 1\text{-}\breve{i}=153^\circ\ 22'$, $1\wedge 1$, mac., $=133^\circ\ 22'$, brach., $123^\circ\ 58'$, $i\text{-}2\wedge i\text{-}2$, ov. $i\text{-}\breve{i}$, $=118^\circ\ 38'$. In acicular crystals.

May be scratched by the nail. G.=5·238. Lustre adamantine; inclining to silky or pearly. Color white. Streak white.

Comp.—Pb Cl=Chlorine 25·5, lead 74·5=100.

Pyr., etc.—B.B. on charcoal fuses readily, spreading out on the coal and volatilizing, gives a white coating, the inner edge of which is tinged yellow from oxyd of lead; the coating in R.F. disappears, tinging the flame azure; with soda gives metallic lead. Added to a salt of phosphorus bead, previously saturated with oxyd of copper, gives the reaction for chlorine (see cerargyrite). Soluble in about 22 parts of hot water.

Obs.—Found by Monticelli and Covelli, in the crater of Vesuvius, after the eruption of 1822, accompanied by chlorid of sodium, and chlorid and sulphate of copper; also by Scacchi and Guiscardi on the lava of 1855.

Named after Dr. Cotugno of Naples. Angles very near those of haidingerite.

---

146. MOLYSITE. Eisenchlorid *Hausm.*, 1819, Handb., 1463, 1847. Chlorid of Iron. Molysite *Dana.*

Incrusting. Color brownish-red, light or dark, and yellow.

Comp.—$Fe^2\ Cl^3$=Chlorine 65·5, iron 34·5=100.

Obs.—Noticed by Hausmann at Vesuvius in 1819, forming a brownish-red incrustation on lavas; and by Scacchi in the same region, as a result of recent eruptions (Eruz. Vesuv., 1850–55), who attributes the yellow color of the lavas about the fumaroles or steam-holes partly to this species.

The existence of a *protochlorid of iron* (Fe Cl) at Vesuvius was announced by Monticelli and Covelli; but this is not confirmed by Scacchi.

Named from *μόλυνσις, stain*, in allusion to its staining the lavas.

---

2. HYDROUS CHLORIDS.

147. CARNALLITE. Carnallit *H. Rose*, Pogg., xcviii. 161, 1856.

Massive, granular; flat planes developed by action of water, but no distinct traces of cleavage; lines of striæ sometimes distinguished, which indicate twin-composition.

Lustre shining, greasy. Color milk-white, but often reddish from mixture of oxyd of iron. Fracture conchoidal. Soluble. Strongly phosphorescent.

Comp.—K Cl+2 Mg Cl+12 $\dot{H}$=(⅓ K+⅔ Mg) Cl+4 $\dot{H}$=Chlorid of magnesium 34·20, chlorid of potassium 26·88, water 38·92=100. Under a more general formula (K, Mg) Cl+4 $\dot{H}$. Analyses: 1, 2, Oesten (Pogg., xcviii., 161); 3, Siewert (Jahresb., 1858, 739); 4, A. Goebel (J.pr. Ch. xcvii. 6):

	Mg Cl	K Cl	Na Cl	Ca Cl	$\dot{Ca}\dddot{S}$	$\overline{\overline{F}}e$	$\dot{H}$
1. Stassfurt, *reddish*	31·46	24·27	5·10	2·62	0·84	0·14	[35·57]=100 Oesten.
2. " "	30·51	[24·27]	4·55	3·01	1·26	[0·14]	[36·26]=100 Oesten.
3. " *white*	36·03	27·41	0·23	——	1·14	——	— —, $\dot{H}$ 36·33—38·01 Siewert.
4. Maman, Persia	34·65	25·62	——	——	——	——	39·67, gangue 0·06=100 Goebel.

The impure carnallite of the mine contains Mg Cl 29·53, K Cl 21·80, Na Cl 7·95, sulphate of potash 10·20, silicate of magnesia and alumina, sand, and boracic acid 1·20, water and loss 29·32. The brown and red color of much of the mineral is due partly to oxyd of iron, which is in hexagonal tables and partly to organic matters (water-plants, infusoria, sponges, etc.). In anal

4, there was some organic substance present with the water; and the carnelian to blood-red color is shown to be due to it.

Pyr., etc.—B.B. fuses easily. Soluble in water, 100 parts of water at 18·75°C. taking up 64·5 parts.

Obs.—Occurs at Stassfurt, where it forms beds in the upper part of the salt formation, alternating with thinner beds of common salt and kieserite, and also mixed with the common salt. Its beds consist of subordinate beds of different colors, reddish, bluish, brown, deep red, sometimes colorless. Sylvine occurs in the carnallite. Also found with salt at Maman in Persia. Its richness in potassium makes it valuable for exploration.

Named after von Carnall of the Prussian mines.

Artif.—Occurs artificially formed in the salt pans at Halle.

148. TACHHYDRITE. Tachhydrit *Ramm.*, Pogg., xcviii. 261, 1856.

Massive; in roundish masses. Two distinct cleavages.

Color yellowish. Transparent to translucent. Very deliquescent on exposure.

Comp.—$(Ca\,Cl + 2\,Mg\,Cl) + 12\,\dot{H} = (\frac{1}{3}\,Ca + \frac{2}{3}\,Mg)\,Cl + 4\,\dot{H}$ = Chlorine 41·17, calcium 7·76, magnesium 9·30, water 41·77=100; or under a more general formula, $(Ca, Mg)\,Cl + 4\,\dot{H}$. Analysis by Rammelsberg (l. c.):

Cl 40·34 Ca 7·46 Mg 9·51 $\dot{H}$ [42·69]=100

Pyr., etc.—Fuses easily. Very soluble; 100 parts of water at 18·75°C. dissolving 160 3 of the salt.

Obs.—From the salt mines of Stassfurt, in thin seams with carnallite and kieserite, in anhydrite.

Named in allusion to its ready deliquescence, from ταχύς, *quick*, and ὕδωρ, *water*.

149. KREMERSITE. Eisenchlorid mit den Chloralkalien *Kremers*, Pogg., lxxxiv. 79, 1851. Kremersit *Kenng.*, Min., 9, 1853.

Isometric. In octahedrons.

Color ruby-red. Easily soluble.

Comp.—$K\,Cl + Am\,Cl + Fe^2\,Cl^3 + 8\,\dot{H} = 2\,(\frac{1}{2}\,K + \frac{1}{2}\,Am)\,Cl + Fe^2\,Cl^3 + 3\,\dot{H}$ = Chlorine 55·86, potassium 12·32, ammonium 5·67, iron 17·65, water 8·50=100. Analysis by Kremers (Pogg., lxxxiv. 79):

Cl	K	Am	Na	Fe	$\dot{H}$
55·15	12·07	6·17	0·16	16·89	[9·56]=100.

It is identical with an artificial salt obtained by Fritzsche.

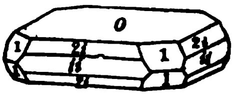
Obs.—From fumaroles at Vesuvius, as a product of sublimation.

---

3. OXYCHLORIDS.

150. MATLOCKITE. *R. P. Greg*, Phil. Mag., IV. ii. 120, 1851.

128



Tetragonal. $O \wedge 1\text{-}i = 128°\ 42'$; $a = 1·2482$. Observed planes, O, I, 1, $2\text{-}i$. $O \wedge I = 90°$, $O \wedge 2\text{-}i = 111°\ 50\frac{1}{2}'$, $O \wedge 1 = 119°\ 34'$, $2\text{-}i \wedge 2\text{-}i$, pyram.,$=97°\ 58'$, basal,$=136°\ 19'$, $1 \wedge 1$, pyram.,$=104°\ 6'$, basal, $120°\ 52'$. Cleavage: **basal imperfect.** Crystals generally tabular.

H. = 2·5—3. G. = 7·21. Lustre adamantine, occasionally pearly Color clear yellowish, sometimes a little greenish. Transparent to translucent.

Comp.—$PbCl+PbO$=Chlorid of lead 55·5, oxyd of lead 44·5=100. Analysis by Dr. R. A Smith (l. c.):

Pb Cl 55·18 Pb O 44·30 Moisture 0·07=99·55.

Rammelsberg found (Pogg. lxxxv. 141), Pb Cl 52·45, Pb O 46·42.

Pyr., etc.—Reacts like mendipite.

Obs.—From an old mine near Cromford in Derbyshire, with phosgenite. Crystals seldom large, but one measures two inches across; according to Kenngott (Min. Not., No. 11), $1 \wedge 1$, basal,= 121° 2′, and $2\text{-}i \wedge 2\text{-}i$, basal edge=136° 17′; also, as a sublimation product at Vesuvius after the eruption of 1858 (R. Cappa, J. pr Ch., lxxx. 381).

151. MENDIPITE. Saltsyradt Bly (Salzsaures Blei) *Berz.*, Ak. H. Stockh., 184, 1823; Ed. J Sci., i. 379, 1824. New ore of lead from Mendip, Peritomous Lead-baryte, *Haid.*, Mohs's Min., ii. 151, 1825. Muriate of Lead, Chlorid of Lead. Plomb chloruré, pt., *Fr.* Kerasine pt. [rest phosgenite] *Beud.* Tr., ii. 502, 1832. Chlor-Spath *Breith.*, Char., 61, 1832. Berzelite *Levy* Min. Heul., ii. 448, 1837. Mendipit *Glock.*, Grundr., 604, 1839.

Orthorhombic; $I \wedge I$=102° 36′. Observed planes, O, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$. Occurs in fibrous or columnar masses, often radiated. Cleavage: I highly perfect; diagonal less perfect.

H.=2·5—3. G.=7—7·1. Lustre pearly and somewhat adamantine upon cleavage faces. Color white, with a tinge of yellow, red, or blue. Streak white. Feebly translucent—opaque.

Comp.—$PbCl+2PbO$=Chlorid of lead 38·4, oxyd of lead 61·6=100. Analyses: 1, Berzelius (Ak. H. Stockh., 1823, Pogg., i. 272, and Ramm. 1st Suppl., 24); 2, Schnabel (ib., 3d Suppl. 78); 3, Rhodius (Ann. Ch. Pharm., lxii. 378):

1. Mendip Hills	Pb Cl 39·82	Pb O 60·18=100	Berzelius.
2. Westphalia	38·70	61·25=99·95	Schnabel.
3. "	32·55	67·78=100·33	Rhodius.

Pyr., etc.—In the closed tube decrepitates and becomes more yellow. B.B. on charcoal fuses easily, and is reduced to metallic lead with elimination of acid vapors, giving the coal a white coating of chlorid of lead, the inner edge of which is yellow from oxyd of lead. With salt of phosphorus bead, previously saturated with oxyd of copper, colors the O.F. azure-blue. Soluble in nitric acid.

Obs.—This rare mineral was formerly found at the Mendip Hills, in Somersetshire, in small radiated crystalline masses on earthy black manganese; it has been met with at Tarnowitz, Silesia, in clay in opaque prismatic crystals; at mine Kunibert near Brillon in Westphalia.

152. SCHWARTZEMBERGITE. Oxychloroïodure de plomb (fr. Atacama) *Domeyko*, Ann. d. M., VI. v. 453, 1864. Schwartzembergite *Dana*.

Rhombohedral. In druses of small crystals. Also in thin amorphous crusts, compact, passing into earthy.

H.=2—2·5. G.=5·7, Schwartzemb.; 6·2—6·3, Liebe. Lustre adamantine Color honey-yellow, when purest; also straw-yellow, inclining to lemon-yellow, sometimes a little reddish. Streak straw-yellow. Brittle.

Comp.—$PbI+2PbO$, Liebe. More probably, as the analysis so gives, $Pb(I, Cl)+2PbO$, with I : Cl=3 : 2. Analysis: K. T. Liebe (Jahrb. Min., 1867, 159):

Pb Cl	Pb I	Pb O	$Pb\dddot{S}$	$Pb\ddot{C}$	$\dddot{S}b$
11·40	30·89	48·92	5·51	1·88	0·91=99·51

Liebe regards all the ingredients as impurities except the iodid and oxyd of lead. Domeyko in an imperfect analysis (l. c.) obtained Pb Cl 22·8, Pb I 18·7, Pb O 47·1, $\dddot{S}$ 2·5, $\dot{C}a$ 1·7, gangue 5·3 =98·1.

Pyr., etc.—Very fusible, like cerargyrite; in fusing loses its color. On charcoal metallic globules. In a matrass abundant violet vapors of iodine. No effervescence with nitric acid, but loses color, becoming first brownish and then white, and, if some water be added, it dissolves completely on heating.

Obs.—Forms crusts in galenite at a mine 10 leagues foom the port of Paposo in the desert of Atacama, where it was discovered by Mr. Schwartzemberg.

153. ATACAMITE. Sable vert cuivreux du Perou, Chaux cuivreuse unie à un peu d'acide muriatique et d'eau, *Rochefoucauld, Baumé & Fourcroy*, Mem. Ac. Paris, 1786 (pub'd in 1788); *Berthollet*, ib., 474 (note added in 1788). Kupfersand, Salzsaures Kupfer, *Karst.*, Tab., 46, 76, 1800. Cuivre muriaté *H.*, Tr., 1801. Muriate of Copper. Atacamit, Salzkupfererz, *Blumenbach*, Handb. Nat., 1805. Kupferhornerz, Atacamit, *Ludwig*, Min., ii. 178, 1804. Smaragdochalcit *Hausm.*, Handb., 1039, 1813. Halochalzit *Breith.*, Handb., 165, 1841. Remolinite *B. & M.*, Min., 618, 1852. Marcylite *Shep.*, Marcy's Expl. Red River, 135, 800, Washington, 1854, Am. J. Sci., II. xxi. 206; Dana, ib., xxiv. 122. Botallackite *A. H. Church*, J. Ch. Soc., II. iii. 212, 1865.

Orthorhombic. *I*∧*I*=112° 20′, *O*∧1-ī=131° 29′; *a*:*b*:*c*=1·131:1:1·492. Observed planes: vertical, *I*, *i*-ī, *i*-ĭ, *i*-2̆, *i*-4̆; domes, 1-ĭ, 1-ī; octahedral, *i*-2̆∧*i*-2̆, ov. *i*-ĭ,=106° 34′, *i*-4̆∧′*i*-4̆, ib.,=139° 4′, 1-ĭ∧1-ĭ, top=105° 40′, *I*∧1=143° 42′, 1∧1, mac.,=126° 40′. Usual in modified rectangular prisms, and rectangular octahedrons. Twins: composition-face *I*; consisting of three individuals. Cleavage: *i*-ĭ perfect, 1-ī imperfect. Occurs also massive lamellar.

H.=3—3·5. G.=4—4·3; 3·7, Breith. Lustre adamantine—vitreous. Color various shades of bright green, rather darker than emerald, sometimes blackish-green. Streak apple-green. Translucent—subtranslucent.

Comp.—$3\,\dot{C}u\,\dot{H}+Cu\,Cl\,\dot{H}=(\frac{3}{4}\,\dot{C}u+\frac{1}{4}\,Cu\,Cl)\,\dot{H}$=Oxyd of copper 53·6, chlorid of copper 30·2, (chlorine 16·0, copper 14·3), water 16·2=100. The ore of Cobija (anal. 1) and *botallackite* (anal. 8) contain half more of water, giving the formula $3\,\dot{C}u\,\dot{H}+Cu\,Cl\,\dot{H}+2$ aq.. Analyses: 1, Berthior (Ann. d. M., III. vii. 542); 2, 3, Bibra (J. pr. Ch., xcvi. 203); 4, 5, F. Field (J. Ch. Soc., vii. 193); 6, Mallet (Ramm., 5th Suppl., 57); 7, 8, Church (J. Ch. Soc., II. iii. 81, 213):

		Cl	$\dot{C}u$	Cu	$\dot{H}$
1.	Bolivia, Cobija	14·92	50·00	18·38	21·75=100 Berthier.
2.	" Algodon	14·96	52·54	13·33	19·17=100 Bibra.
3.	" "	15·07	52·40	14·00	18·53=100 Bibra.
4.	Copiapo	14·94	——	56·46	17·79 Field.
5.	"	15·01	——	56·24	18·00 Field.
6.	Chili	16·33	55·94	14·54	12·96, quartz 0·08=99·85 Mallet.
7.	Cornwall	15·20	54·32	13·57	16·91=100 Church.
8.	*Botallackite*	14·51	66·25	——	22·60=103·36 Church.

Anal. 4 corresponds to Cu Cl 28·22, Cu 53·99, $\dot{H}$ 17·79; and 5 to Cu Cl 28·35, $\dot{C}u$ 53·62, $\dot{H}$ 18·00 For other analyses see Ulex, Ann. Ch. Pharm, lxix. 361.

Pyr., etc.—In the closed tube gives off much water, and forms a gray sublimate. B.B. on charcoal fuses, coloring the O.F. azure-blue, with a green edge, and giving two coatings, one brownish and the other grayish-white; continued blowing yields a globule of metallic copper; the coatings touched with the R.F. volatilize, coloring the flame azure-blue. In acids easily soluble.

Obs. This species was originally found in the state of sand in the Atacama province, northern part of Chili. It occurs in different parts of Chili, especially at Los Remolinos; also in veins in the district of Tarapaca, Bolivia; at Tocopilla, 16 leagues north of Cobija, an imporant locality. in Bolivia; with malachite in South Australia; at the extraordinary malachite locality in the Serra do Bembe, near Ambriz, on the west coast of Africa; at the Estrella mine in southern Spain; at St. Just in Cornwall, in crusts and stalactitic tubes. Botallackite occurs at the Botallack mine, Cornwall, in thin crusts of minute interlacing crystals, closely investing killas; Schwarzenberg in Saxony; also supposed to invest some of the lavas of Vesuvius, but questioned by Scacchi, the mineral so called being a basic sulphate (Mem. Incend. Vesuv., 1855).

It is sometimes ground up in Chili, and sold under the name of *Arsenillo* as sand for letters.

Marcylite of Shepard, as originally described, was an impure atacamite of a black color; a trial afforded Shepard copper 54·30, O and Cl 39·20, $\dot{H}$ 9·50. G.=4—4·1. From the south part of the Red River, near the Wachita Mts. (See further under Melaconite, p. 137.)

153A. TALLINGITE. *A. H. Church*, J. Ch. Soc., II. iii. 213, 1865.

In thin crusts, consisting of irregular aggregations of minute globules, appearing botryoidal under the microscope. Subcrystalline.

H.=3. G.=3·5 (approximate). Color bright-blue, inclining to green. Streak white. Subtranslucent. Fragile. Hygroscopic.

Comp.—$4\dot{C}u\dot{H}+CuCl\dot{H}+3aq$ =Chlorid of copper 22·55, oxyd of copper 53·29, water 24·16=100; or chlorine 11·91, oxyd of copper 66·60, water 24·16=102·67. Church (J. Ch. Soc., II. iii. 77) obtained $\dot{C}u$ 66·24, Cl 11·33, which corresponds to

Cl 11·33 $\dot{C}u$ 53·57 Cu 10·11 $\dot{H}$ 24·99=100.

In another blue Cornwall mineral Church found (ib., 213) Oxyd of copper 67·25, chlorine 8·73, water 26·56=102·54; which gives the formula $6\dot{C}u\dot{H}+CuCl\dot{H}+5aq$=Oxyd of copper 67·25, chlorine 8·58, water 26·13=101·96. Church says the less hydrated copper sulphates and chlorids are green, the more hydrated blue.

Pyr., etc.—In vacuo loses hygroscopic water, remaining blue. At 100° C. rapidly becomes green, losing considerable water. Insoluble in water, but easily soluble in dilute acids and in ammonia.

Obs.—Occurs at the Botallack mine, Cornwall. Named after R. Talling, of Lostwithiel, by whom the mineral was collected.

Artif.—A similar compound has been formed by Kane, and by Graham, by the action of water on NH^3CuCl; its formula is $4\dot{C}u\dot{H}+CuCl^4+aq$.

154. PERCYLITE. *H. J. Brooke*, Phil. Mag., III. xxxvi. 131, 1850.

Isometric. In minute cubes. Observed planes: *O*, 1, *I*, *i*-2.

H.=2·5. Color sky-blue. Streak similar to the color.

Comp.—According to Percy, contains, besides some water, lead, chlorine, copper, and probably oxygen, with Pb : Cl : Cu=2·66 : 0·84 : 0·77; whence Percy suggests the formula $(PbCl+PbO)+(CuCl+CuO)+aq$.

Pyr.—In the closed tube yields water and odorless fumes. B.B. tinges the flame green with blue on the edges. With borax reacts for copper.

Obs.—Found with gold, and supposed to be from Sonora, Mexico.

APPENDIX TO CHLORIDS, BROMIDS, AND IODIDS.

155. CHLORID OF MAGNESIUM. 156. CHLORID OF MANGANESE.

Chlorid of magnesium and chlorid of manganese, according to Scacchi (Mem. Incend. Vesuv., 1855), probably occur in the saline incrustations formed at the eruption of Vesuvius in 1855. The supposed existence of the manganesian chlorid was ascertained by treating the crust with distilled water and testing with ferrocyanid of potassium, when a white precipitate was thrown down, which acquired after a while a pale rose tint; and also in other ways.

157, 158. IODID OF ZINC.—BROMID OF ZINC.—Iodine and bromine are stated by Mentzel to occur along with a cadmiferous zinc in Silesia, and hence it is inferred that iodid and bromid of zinc exist in nature, though not yet distinguished.

Besides the preceding species, the following also contain chlorine: Sodalite and Pyrosmalite, and some Nephelite, Nosite, and Mica among silicates; some Apatite among phosphates; Boracite among borates; Phosgenite among carbonates.

IV. FLUORINE COMPOUNDS.

1. ANHYDROUS.

1. FLUORITE GROUP.

159. FLUORITE	$Ca\,F$	161. FLUOCERITE	$Ce\,F$
160 YTTROCERITE	$(Ca, Ce, Y)\,F$	162. FLUOCERINE	

2. FLUELLITE GROUP. Contain Aluminum.

163. FLUELLITE

3. CRYOLITE GROUP. Contain Aluminum and Sodium or Calcium.

164. CRYOLITE	$3\,Na\,F + Al^2\,F^3$	166. CHIOLITE	$3\,Na\,F + 2\,Al^2\,F^3$
65. ARKSUTITE	$(Ca, Na)^2\,F + Al^2\,F^3$	167. CHODNEFFITE	$2\,Na\,F + Al^2\,F^3$

2. HYDROUS.

168. PACHNOLITE	$3\,(Ca, Na)\,F + Al^2\,F^3 + 2\,\dot{H}$	170. GEARKSUTITE	$Ca^2\,F + Al^2\,F^3 + 4\,\dot{H}$
169. THOMSENOLITE	$2\,(Ca, Na)\,F + Al^2\,F^3 + 2\,\dot{H}$	171. PROSOPITE	

159. **FLUORITE** or **FLUOR.** Fluores lapides gemmarum similes sed minus duri—qui ignis calore liquescunt [whence he derives the name]—Colores varii, jucundi, (1) rubri, (2) purpurei (vulgo amethysti), (3) candidi, (4) lutei, (5) cineracei, (6) subnigri, etc. [with mention also of its use as a flux in smelting], *Agric.*, Berm., 458, 1529; *Germ.* Flusse *id.*, Interpr., 464, 1546. Var.—Chlorophane (fr. Nertschinsk) *Th. De Grotthaus*; Delameth., J. de Phys., xlv. 398, 1794. Ratofkit *Fischer*, John Ch. Unters., vi. 232, 1812.

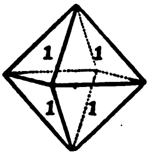
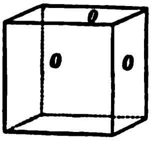
Isometric. Observed planes: O; I; 1, 2, 3; i-2, i-3, i-$\frac{5}{3}$, i-$\frac{4}{3}$; 2-2, 3-3, $\frac{3}{2}$-$\frac{3}{2}$; 4-2, $\frac{10}{3}$-$\frac{5}{2}$, $\frac{11}{3}$-$\frac{11}{5}$, 7-$\frac{7}{3}$, $\frac{25}{2}$-$\frac{25}{6}$. Figs. 1 (common), 2 to 8, 10, 11, 16, 18, similar to 24 (planes 1, and 3-3), 26. Cleavage: octahedral, perfect. Twins: composition-face, 1, f. 50; also f. 129, in which the composition is parallel to each octahedral face. Massive. Rarely columnar; usually granular, coarse or fine. Crystals often having the surfaces made up of small cubes, or cavernous with rectangular cavities.

H.=4. G.=3·01—3·25; 3·1800—3·1889, Kenngott, from 43 specimens the mean 3·183. Lustre vitreous; sometimes splendent; usually glimmering in the massive varieties. Color white, yellow, green, rose and crimson-red, violet-blue, sky-blue, and brown: wine-yellow, greenish and violet-blue, most common; red, rare. Streak white. Transparent—subtranslucent. Brittle. Fracture of fine massive varieties flat-conchoidal and splintery. Sometimes presenting a bluish fluorescence. Phosphoresces when heated.

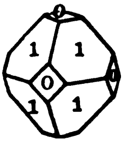
124



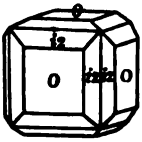
125



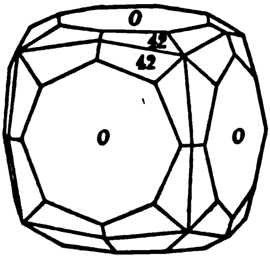
126



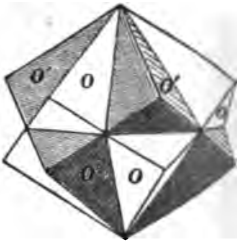
127



128



129



Comp., Var.—Fluorid of calcium, Ca F=Fluorine 48·7, calcium 51·3=100. Berzelius found 0·5 of phosphate of lime in the spar of Derbyshire. The presence of chlorine (or muriatic acid in old chemistry) was detected early by Scheele. Kersten found it in fluor from Marienberg and Freiberg. The bright colors, as shown by Kenngott, are lost on heating the mineral; they are attributed mainly to different hydrocarbon compounds by Wyrouboff (Bull. Soc. Ch., II. v. 334, 1866), the crystallization having taken place from aqueous solution.

Var. 1. *Ordinary; (a)* cleavable or crystallized, very various in colors; (*b*) coarse to fine *granular;* (*c*) earthy, dull, and sometimes very soft. A soft earthy variety from Ratofka, Russia, of a lavender-blue color, is the *ratofkite.*

The finely-colored fluors have been called, according to their colors, *false* ruby, topaz, emerald, amethyst, etc. The colors of the phosphorescent light are various, and are independent of the actual color: and the kind affording a green color is (*d*) the *chlorophane* (fr. χλωρός, *green*, and φαίνω, *I appear*) or *pyro-emerald.*

Breithaupt obtained for fluor G.=3·017, fr. Alston Moor, Cumberland, white; 3·170, Euba, blue; 3·176, ib., white; 3·171, fr. Siberia, blue; 3·183, ib., white; 3·166, fr. near Marienberg, green; 3·172, ib., blue; 3·169, fr. Bösenbrunn in Voigtland, green; 3·186, ib., blue; 3·188, ib., white; 3·185, fr. Cornwall, fluorescent; 3·188, fr. Switzerland, rose-red; 3·193, fr. near Freiberg, green; 3·255, fr. Mexico, emerald-green transparent oct.; 3·324—3·357, fr. Siberia, violet-blue.

2. *Antozonite* of Schönbein. The dark violet-blue fluor of Wölsendorf, Bavaria, afforded Schrötter 0·02 p. c. of ozone, which Schönbein (J. pr. Ch., lxxxiii. 95, lxxxix. 7) showed to be *antozone*, whence his name for this variety. Its strong antozone odor is said often to produce headache and vomiting in the miners. Schafhäutl states (Ann. Ch. Pharm., xlvi. 344) that this fluor contains, Nitrogen 0·02073, hydrogen 0·00584, carbon 0·0365, chlorous acid 0·08692. But Wyrouboff discredits, in part, his results; he himself obtained Carbon 0·0170, hydrogen 0·0038, with $\bar{A}l$ 0·0180, $\bar{F}e$ 0·0032, $\dot{F}e$ 0·0025, Cl 0·0071. Wyrouboff attributes the various colors to compounds of carbon and hydrogen, derived from a slight infusion of organic matters in the solvent waters; he found (Bull. Soc. Ch., II. v. 334, 1866) that the blue and violet colors changed to purple on heating, and supposes that two C H substances, a blue and a red, were present, the former more volatile, and therefore leaving the color reddish after partial heating.

Pyr., etc.—In the closed tube decrepitates and phosphoresces. B.B. in the forceps and on charcoal fuses, coloring the flame red, to an enamel which reacts alkaline to test paper. With soda on platinum foil or charcoal fuses to a clear bead, becoming opaque on cooling; with an excess of soda on charcoal yields a residue of a difficultly fusible enamel, while most of the soda sinks into the coal; with gypsum fuses to a transparent bead, becoming opaque on cooling. Fused in an open tube with fused salt of phosphorus gives the reaction for fluorine. Treated with sulphuric acid gives fumes of hydrofluoric acid which etch glass.

Phosphorescence is obtained from the coarsely powdered spar below a red heat. At a high temperature it ceases, but is partially restored by an electric discharge.

Obs.—Sometimes in beds, but generally in veins, in gneiss, mica slate, clay slate, and also in limestones, both crystalline and uncrystalline, and sandstones. Often occurs as the gangue of metallic ores. In the North of England, it is the gangue of the lead veins, which intersect the coal formation in Northumberland, Cumberland, Durham, and Yorkshire; the Cumberland fluor often contains drops of fluid within, especially the green variety (Greg and Lettsom). In Derbyshire it is abundant, and also in Cornwall, where the veins intersect metamorphic rocks. Common in the mining district of Saxony; fine near Kongsberg in Norway. In the dolomites of St. Gothard it occurs in pink octahedrons; at Münsterthal in Baden in flesh-red hexoctahedrons. It has been detected in cannel coal by Prof. Rogers.

In *Maine*, on Long Island, Blue Hill Bay, in veins. In *N. Hampshire*, at N. village of Westmoreland, 2 m. S. of meeting-house, white, green, purple, constituting a vein in quartz; at the Notch in the White Mts., green oct. in quartz, rare. In *Vermont*, at Putney, in green cubes. In *Massachusetts*, at the Southampton lead mine. In *Connecticut*, at Trumbull, the *chlorophane* var., with topaz, in two veins, each 18 in. wide, in gneiss; at Plymouth, in octahedral and dodecahedral crystals; at Willimantic, purple, in a vein in gneiss, and also sparingly at the topaz vein; at the Middletown lead mine. In *New York*, in Jefferson Co., at Muscolonge lake, formerly abundant, in gigantic cubes, sometimes modified (fig. 128), of grass-green and pale-green shades, in granular limestone; in St. Lawrence Co., at Rossie and Johnsburgh, rarely in fine crystals; at Lockport, occasionally in cubes, with selenite and celestine in limestone; also similarly near Rochester and Manlius; Amity, in thin seams, with spinel and tourmaline. In *New Jersey*, near the Franklin Furnace. In *Virginia*, near Woodstock, in limestone; on the Potomac, at Shepardstown, in white limestone In *Illinois*, Gallatin Co., for 30 m. along the Ohio, 10 to 15 m. below Shawneetown, and at other places, dark purple, often in large crystals, in carboniferous limestone, with galenite, and through the soil. In *California*, at Mt. Diablo, rare in white cubes. In *Arizona*, in Castle Dome dist., white, pink, green, purple. In *Nova Scotia*, at Mabon harbor, green. Near Lake Superior, a few miles from the N.E. corner of Thunder bay, in large violet cubes on amethyst, affording magnificent specimens.

Alt.—Fluor spar is slightly soluble in waters containing bicarbonate of lime in solution. The alkaline carbonates decompose it, producing carbonate of lime or *calcite*, and a subsequent change of the calcite may produce other forms of pseudomorphs. Fluor spar occurs changed to quartz, by substitution, and also to limonite, hematite, lithomarge, psilomelane, calamine, smithsonite, cerussite, kaolinite.

160. **YTTROCERITE.** Yttrocerit *Gahn & Berzelius*, Afh., iv. 1814. Yttrocererit *Leonh.*, Handb., 578, 1826. Yttria fluatée *Fr.* Fluate of Cerium and Yttria. Ytterflussspath, Flussyttrocalcit, *Germ.* Yttrocalcit *Glock.*, Syn., 283, 1847.

Massive; crystalline-granular and earthy. Cleavage: in two directions inclined to one another 108° 30′.

H.=4—5. G.=3·447, Berzelius. Lustre glistening; vitreous—pearly. Color violet-blue, inclining to gray and white, often white; sometimes reddish-brown. Fracture uneven.

Comp.—Contains CaF, CeF, and YF, in different proportions. Analyses by Gahn and Berzelius (Afhandl., iv. 151, and Schw. J., xvi, 241):

Ca	$\bar{\mathrm{C}}\mathrm{e}$	Y	FH
47·63	18·21	9·11	25·05
50·00	16·45	8·10	25·45

Pyr., etc.—In the closed tube gives water. B.B. on charcoal alone infusible; with gypsum the yttrocerite of Finbo fuses to a bead, not transparent, and that of Broddbo is infusible. With the three fluxes the Finbo mineral behaves like fluor spar; the glass is, however, yellow in the oxydizing flame as long as hot, and becomes opaque sooner than the glass given by fluor spar In a pulverized state it dissolves completely in heated muriatic acid, forming a yellow solution.

Obs.—Occurs sparingly at Finbo and Broddbo, near Fahlun in Sweden, imbedded in quartz, and associated with albite and topaz. Also at Amity, Orange Co., N. Y.; in Mass., probably Worcester Co.; at Mt. Mica, in Paris, Maine. The Amity mineral has been examined by J. E. Teschemacher. The Massachusetts mineral afforded Dr. C. T. Jackson (Proc. Nat. H., Bost., 1844, 166) lime, yttria, oxyd of cerium, with some $\bar{\mathrm{A}}\mathrm{l}$, $\bar{\mathrm{F}}\mathrm{e}$, and $\ddot{\mathrm{S}}\mathrm{i}$, and a loss of 19·4. The mineral is mixed with fluorite in the vein, and probably the specimen analyzed was not pure from it.

Yttrocerite has been considered a fluor spar in which part of the lime is replaced by oxyds of cerium and yttrium. The angle of cleavage reported, 108° 30′, differs but a degree from the angle between faces of a regular octahedron.

161. FLUOCERITE. Neutralt flusspatssyradt Cerium *Berz.*, Afh., vi. 56, 1818. Neutrales flusssaures Cerer, Flusscerium ceriumfluat, *Germ.* Neutral Fluate of Cerium. Cerium fluaté *Fr.* Fluocérine *Beud.*, Tr., ii. 519, 1832. Fluocerit *Haid.*, Handb., 500, 1845.

Hexagonal. In hexagonal prisms and plates. Cleavage: basal most distinct. Also massive.

H.=4–5. G.=4·7. Lustre weak. Color dark tile-red or almost yellow; deeper when the mineral is wet. Streak white, or slightly yellowish. Subtranslucent—opaque.

Comp.—$\mathrm{Ce\,F} + \mathrm{Ce^2\,F^3}$, Berzelius, who obtained in an analysis (l. c.) $\ddot{\mathrm{Ce}}$ 82·64, $\dot{\mathrm{Y}}$ 1·12.

Pyr., etc.—In the closed tube yields water, and at a high temperature corrodes the glass; the water contains fluorine, and tinges Brazil-wood paper yellow; the assay changes from yellow to white by heat. B.B. on charcoal infusible, but darkens in color. With soda it is not dissolved, but divides and swells up; the soda is absorbed by the charcoal, and leaves a gray mass on the surface.

Obs.—Occurs at Finbo and Broddbo near Fahlun, in Sweden, imbedded in quartz and albite, accompanying pyrophysalite and orthite.

162. FLUOCERINE.—(Basisk flusspatssyradt Cerium *Berz.*, Afh. vi. 64. Basisches Fluorcerium. Basic fluocrine. Basicerine *Beud.* Fluocerine *Hausm.*, 1847.) Isometric? Supposed to show traces of the rhombic dodecahedron; usually massive. H.=4·5–5. Lustre vitreous or resinous. Color a fine yellow, with some red, and when impure, brownish-yellow. Streak yellow, brownish. Subtranslucent to opaque.

Formula, $\mathrm{Ce^2\,F^3} + 3\,(\mathrm{Ce_2\,O_3} + \dot{\mathrm{H}})$ = Cerium 17·6, fluorine 10·9, sesquioxyd of cerium 66·4, water 5·1=100. Berzelius obtained in his analysis (l. c.) $\ddot{\mathrm{Ce}}$ 84·20, and $\dot{\mathrm{H}}$ 4·95, and deduced as its composition $\mathrm{Ce\,F} + 3\,\dot{\mathrm{C}}\mathrm{e}\,\dot{\mathrm{H}}$.

B.B. on charcoal infusible, at a low red heat appears almost black; on cooling it becomes dark brown, clear red, and finally yellow. With the fluxes behaves like fluocerite.

From Finbo, with fluocerite.

A mineral from Bastnäs afforded Hisinger (Ak. H. Stockh., 1838, 189), Sesquioxyd of Ce (and La) 86·43, fluorid ibid. 50·15, water 13·41, which corresponds to the formula $\mathrm{Ce^3\,F^3} + \mathrm{Ce^2\,O^3} + 4\,\dot{\mathrm{H}}$. Named *Bastnæsite* by Huot, Min., i. 296, 1841.

163. FLUELLITE. Fluellite *Levy*, Ann. Phil., II. viii. 242, 1824. Fluate of Alumine, Fluorid of Aluminum.

Orthorhombic; in acute rhombic octahedrons with truncated apex. $1 \wedge 1$, pyram.,=109° 6′, 82° 12′, and, basal, 144°; $I \wedge I$=105° nearly.

H.=3. Lustre vitreous. Color white. Transparent.

Comp.—Fluorine and aluminum, according to Wollaston.

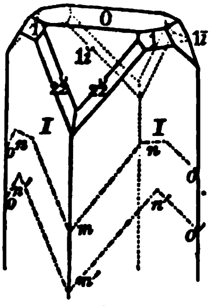
Obs.—Fluellite is a rare mineral found at Stenna-gwyn, in Cornwall, in minute crystals on quartz, along with wavellite and uranite.

164. CRYOLITE. Chryolith, Thonerde mit Flussäure *Abildgaard*, Scherer's J., ii. 502, 1799; d'Andrada, ib., iv. 37, 1800. Kryolith *Karst.*, Tab., 28, 78, 1800; id. (with anal.) *Klapr.*, J. de Phys., li. 473, 1800, Beitr., iii. 207, 1802; *Vauq.*, Ann. Ch., xxxvii. 89, 1801. Alumine fluatée alcaline *H.*, Tr., ii. 1801. Cryolite. Eisstein *Germ.*

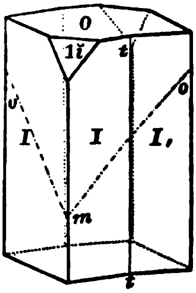
Orthorhombic? $I \wedge I$=88° 30′ to 88°, $O \wedge I\text{-}\bar{i}$=125° 57′; $a:b:c$=1·3789 : 1 : 1·0265. Observed planes as in the figures. $O \wedge 1\text{-}\breve{i}$=126° 40′, $O \wedge 1$

117° 30′. Prisms often a little tapering, and marked with striæ parallel to the edges $I/1\text{-}\breve{i}$, and sometimes also to edges $I/1\text{-}\bar{i}$, and $I/1$, as indicated by dotted lines *mno* in fig. 130. Twins: composition-face I, reëntering angle $I\wedge I=177°$, f. 131; no reëntering angle or apparent suture on plane O. Cleavage: basal perfect; diagonal less so. Massive, cleavable. H. = 2·5. G. = 2·9 — 3·077, fr. Greenland; 2·95 — 2·96, fr. Miask, Durnef. Lustre vitreous; slightly pearly on O. Color snow-white; sometimes reddish or brownish to brick-red and even black. Subtransparent — translucent. Immersion in water increases the transparency. Brittle.

130



131



Comp.—3 Na F+Al² F⁶=Aluminum 13·0, sodium 32·8, fluorine 54·2=100. Analyses: 1, Klaproth (l. c.); 2, Berzelius (Ak. H. Stockh., 315, 1823); 3, Chodnef (Verh. Ges. Min. St. Pet., 1845–46, 219); 4, Durnef (Pogg., lxxxiii., 588):

	F	Al	Ca	Na
1. Greenland	——	12·8	——	26·8 Klaproth.
2. "	[54·07]	13·00	——	32·93 Berzelius.
3. "	[53·23]	13·23	——	32·71, Mn, Mg 0·83 Chodnef.
4. Miask	[53·38]	13·41	0·35	32·31, Mn, Fe 0·55 Durnef.

Pyr., etc.—Fusible in the flame of a candle. B.B. in the open tube heated so that the flame enters the tube, gives off hydrofluoric acid, etching the glass; the water which condenses at the upper end of the tube reacts for fluorine with Brazil-wood paper. In the forceps fuses very easily, coloring the flame yellow. On charcoal fuses easily to a clear bead, which on cooling becomes opaque; after long blowing, the assay spreads out, the fluorid of sodium is absorbed by the coal, a suffocating odor of fluorine is given off, and a crust of alumina remains, which, when heated with cobalt solution in O.F., gives a blue color. Soluble in sulphuric acid, with evolution of hydrofluoric acid.

Obs.—Occurs in a bay in Arksut-fiord, in West Greenland, at Evigtok, about 12 m. from the Danish settlement of Arksut, where it constitutes a large bed or vein in gneiss, and contains galenite, sphalerite, siderite, pyrite, arsenopyrite, fluorite, columbite, cassiterite, all often in fine crystals. The exposure of the cryolite is about 300 feet in length. It is shipped in large quantities to Europe, and to the United States (Pennsylvania), where it is used for making soda, and soda and alumina salts; also of late, in Pennsylvania, for the manufacture of a white glass which is a very good imitation of porcelain. It has also been used for the manufacture of aluminum. The first specimens of cryolite came through Denmark from Greenland, and the earliest notice of it was by Schumacher in the Abh. Nat. Ges. Copenhagen, iv. 1795. The locality was described from personal observation by Gieseckė in Ed. Encyc., x. 97, and Ed. Phil. J., vi. 141, 1822; and recently by J. W. Taylor in the Q. J. G. Soc., xii. 140. Taylor states that the cryolite is not white, except within 10 to 15 feet from the surface, and that below this it becomes dark-colored, and even black. He attributes the bleaching above to the heat of two trap-dykes; but as the dykes are not in contact with the cryolite, and the evidence is not clear that they ever overlaid it, this cause may be questioned. The contained ores and other minerals are most abundant near the junction with the gneiss.

Dr. Hagemann described the crystals (Am. J. Sci., II. xlii. 268) as orthorhombic. The author obtained the above figures from specimens kindly furnished by Dr. H. They occur implanted on the massive cryolite. The twin, by the absence of a reëntering angle on plane O, appears to prove that the form is orthorhombic and not oblique. Yet Descloizeaux states that the optical characters, as observed by him, indicate a monoclinic form. Owing to the striations of the crystals and their minuteness, the measurements of the author were not very satisfactory. $O\wedge 1\text{-}\breve{i}$, in front, gave 126° 40′ (5 measurements 126° 30′—126° 40′, and three of them 126° 40′), $O\wedge 1\text{-}\breve{i}$, back, 125° 10′—125° 37′, $O\wedge 1\text{-}\bar{i}$ about 126°, $1\text{-}\bar{i}\wedge 2\text{-}\breve{i}$ about 159° 40, $O\wedge 1$ about 115° 30′, $1\text{-}\breve{i}$, front, $\wedge 1\text{-}\breve{i}$, back, $=71°$ 25′. The angles obtained point to a monoclinic form, and but for the twin, would have been regarded as decisive. The angle *I* ∧ *I* varied from 89° 30′ to 85°. Th planes 2-2̆ and 1 were not observed on the back of the crystal. Hagemann found 1-ī ∧ 1-ī=70° 30′

165. ARKSUTITE. Arksudite *G. Hagemann*, Am. J. Sci., II. xlii. 94, 1866.

Granular massive. Cleavage: one quite distinct.

H.=2·5. G.=3·029—3·175. Lustre vitreous, somewhat pearly on a cleavage face. Color white. Translucent. Brittle.

Comp.—2 (Ca, Na) F + Al^2F^6, with Ca : Na=1 : 3,=Aluminum 18·6, sodium 23·3, calcium 6·3, fluorine 51·3=100. Analysis: Hagemann (l. c.):

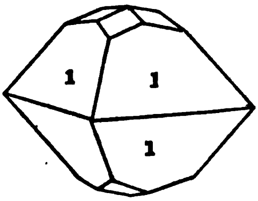
F	Al	Ca	Na	Ḣ	Insol.
51·03	17·87	7·01	23·00	0·57	0·74=100·22

Pyr., etc.—Fuses at a red heat, yielding no water.

Obs.—From the cryolite vein of Iviktok, near Arksut-fiord, in South Greenland. The specific gravity 3·175, it is said, may have owed its excess above that of the other trials to the presence of a little pyrite.

166. CHIOLITE. Chiolith (fr. Miask) *Hermann & Auerbach*, J. pr. Ch., xxxvii. 188, 1846

131 A



Ilmen Mts.

Tetragonal. *O* ∧ 1-*i*=133° 49½′; *a*=1·04184. Observed form f. 131 A. 1 ∧ 1, pyr.,=108° 23′; 1 ∧ 1, basal, = 111° 40′; 1 ∧ 1, over summit, = 68° 20′. Cleavage indistinct. Twins: composition-face 1, as in f. 50. Occurs massive granular, resembling cryolite; structure crystalline.

H.=4. G. = 2·72, Hermann; 2·842 — 2·898, Ramm. Color snow-white. Lustre somewhat resinous. Translucent.

Comp.—3 NaF + 2 Al^2F^6=Fluorine 58·0, aluminum 18·6, sodium 23·4=100. **Analyses**: 1, Hermann (l. c.); 2, Rammelsberg (Pogg., lxxiv. 315, 1848):

	Al	Na	F	
1. Miask	18·69	23·78	[57·53]	Hermann.
2. "	(½) 18·44	24·05	[57·51]	Ramm.

Pyr.—Like cryolite.

Obs.—From the Ilmen Mts., near Miask, where it occurs in granite, with topaz, fluorite, phenacite, and cryolite.

For Kokscharof on cryst., see Verh. Min. Ges. St. Pet., 1850, '51, and Min. Russl., iv. 393.

Kenngott makes crystals from the topaz mine of Mursinsk orthorhombic (Ber. Ak. Wien, xi 980), with the prismatic angle 124° 22′, and having the acute edge of the prism truncated, and *I* ∧ *i*-ī=117° 49′.

167. CHODNEFFITE. Chiolith (fr. Miask) *v. Wörth & Chodnef*, Verh. Russ. Min. Ges., 1845–46, 208, 216, 1846. Chodneffite *Dana*, Min., 234, 1850; Cryolite, ib., 97, 1854. Nipholith *Naum.*, Min., 219, 1864.

G.=2·62—2·77, v. Wörth; 3·00, Ramm. Like chiolite in physical characters.

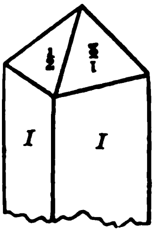
Comp.—2 Na F + Al^2F^6=Fluorine 56·4, aluminum 16·3, sodium 27·3=100. **Analyses**: 1, A Chodnef (l. c.); 2, Rammelsberg (Pogg., lxxiv. 314):

	F	Al	Na
1. **Miask**	½ [56·82]	16·48	26·70 Chodnef.
2. "	½ [56·57]	15·75	27·68 Ramm.

Obs.—Rammelsberg by his analyses appears to show that besides cryolite there are two other related compounds at Miask, one of his analyses sustaining the chiolite of Hermann, and the other the chiolite of Wörth and Chodnef; and on the basis of his results this species is made distinct from the others.

168. PACHNOLITE. Pachnolit *Knop.*, Ann. Ch. Pharm., cxxvii. 61, 1863.

132



Monoclinic. *I* ∧ *I*=98° 34′, ½ ∧ ½=108° 15′, *I* ∧ ½=153° 37′, *O* ∧ *I*=90° 20′, front edge of pyr. on front edge of prism 146° 45′, Descl. Twins: composition-face *i-ì* (f. 132); crystals always twins; ½ ∧ ½ adjacent 94° 13′. Cleavage: *O* and *I*, unequal. Lustre vitreous. Colorless to white. Transparent to subtransparent. Optic-axial plane and one bisectrix normal to *i-ì*; and inclined 10°—15° to a normal to *i-i*, and 23° 15′—18° 15′ to a normal to the front edge of the pyramid.

Comp.—3 (Ca, Na) F+Al^2F^6+2 $\dot{\text{H}}$, with Ca : Na=3 : 2=Fluorine 51·12, aluminum 12·29, calcium 16·14, sodium 12·38, water 8·07=100. Analyses: 1, Knop (l. c.); 2, G. Hagemann (Am. J. Sci., II. xli. 119):

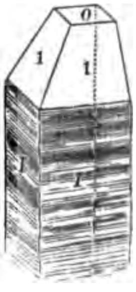
F	Al	Ca	Na	$\dot{\text{H}}$
50·79	13·14	17·25	12·16	9·60=102·94 Knop.
51·15	10·37	17·44	12·04	8·63=99·63 Hagemann.

Pyr., etc.—In the closed tube, heated gently, yields water which is neutral; at a higher heat, that which is acid. Heated rapidly it is decomposed with crackling, and the formation of a white cloud which condenses on the walls of the tube. Decomposed by sulphuric acid, giving out fluohydric acid.

Obs.—Incrusts the cryolite of Greenland, being a result of its alteration. The pyramidal planes sometimes have a stair-like appearance, from interrupted combination.

169. THOMSENOLITE. Dimetric Pachnolite *G. Hagemann*, Am. J. Sci., II. xlii. 93, 1866. Thomsenolite *Dana*.

133



Monoclinic. *I*∧*I* about 89°; *O*∧*I* approx. 92° and 88°; *O*∧1=121°—124°, Dana. Prisms slender, a little tapering; *I* horizontally striated. Cleavage: basal very perfect. Also massive, opal, or chalcedony-like.

H.=2·5—4. G.=2·74—2·76, of crystals. Lustre vitreous, of a cleavage-face a little pearly, of massive waxy. Color white, or with a reddish tinge. Transparent to translucent.

Comp.—2 (Ca, Na) F+Al^2F^6+2 $\dot{\text{H}}$, with Ca : Na=7 : 3=Fluorine 52·2, aluminum 15·0, calcium 15·4, sodium 7·6, water 9·8=100. Analysis: Hagemann (l. c.):

	F	Al	Ca	Na	$\dot{\text{H}}$	$\ddot{\text{Si}}$
Crystals	50·08	14·27	14·51	7·15	9·70	2·0=97·71

The compact afforded Dr. Hagemann a similar result.

Pyr., etc.—Fuses more easily than cryolite to a clear glass. The massive decrepitates remarkably in the flame of a candle. In powder easily decomposed by sulphuric acid.

Obs.—Found with pachnolite on the cryolite of Greenland, and a result of the alteration of cryolite.

The crystals often have an ochre-colored coating, especially the terminal portion; and on this account, and the striated tapering sides, the measurements are only approximations. The mineral was first noticed by Dr. Julius Thomsen of Copenhagen, the originator of the cryolite industry, after whom it is here named. It differs strikingly from pachnolite in its pearly basal cleavage and its nearly square prisms; and from cryolite in the horizontal striæ of the same and the facility of cleavage. The compact variety, first observed by Dr. Hagemann (to whom the author is indebted for his acquaintance with it), has much of the aspect of chalcedony; it incrusts cryolite or occupies seams or cavities in it, and is covered by the chalky gearksutite; the incrustations are sometimes half an inch or more thick.

169A. **Hagemannite.** Hagemannite *Shepard*, Am. J. Sci., II. xlii. 246, 1866. Closely resembles in aspect and condition the compact thomsenolite, but passes sometimes into a yellow, opaque, jaspery variety. It incrusts the cryolite, and also constitutes seams $\frac{1}{8}$ to $\frac{1}{4}$ in. thick. It sometimes traverses a drusy ferruginous pachnolite. It is ochre-yellow to wax-yellow in color, rarely faint greenish, dull, or with only a faintly glimmering lustre, and looks like an iron flint, or the yellow chloropal of Alar, Bavaria. H.=3—3·5. G.=2·59—2·60. Adheres but feebly to the tongue.

Hagemann obtained in an analysis F 40·30, Al 12·06, Fe 5·96, Mg 2·30, Ca 11·18, Na 8·45, Si 7·79, $\dot{\mathrm{H}}$ 10·44. Decrepitates surprisingly in the flame of a candle.

The analysis corresponds to the atomic ratio for F, Si, (Al, Fe), (Mg, Ca, Na), 4 : 1 : 1 : 2. Taking 2 F for the Si, to make Si F^2, it leaves only 2 F for the bases. No probable formula can be deduced. Excluding the Si, Mg, Fe, the composition is that of thomsenolite.

170. GEARKSUTITE.

Earthy, kaolin-like in aspect.
H.=2. Lustre dull. Color white, opaque.

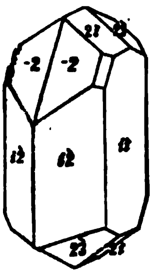
Comp.—$\mathrm{Ca}^2\,\mathrm{F}+\mathrm{Al}^2\,\mathrm{F}^3+4\,\dot{\mathrm{H}}$, or essentially like that of arksutite, excepting the water and the presence of but little soda. Analysis: G. Hagemann (private contrib.):

F	Al	Ca	Na	$\dot{\mathrm{H}}$
41·18	15·52	19·25	2·46.	20·22.

Obs.—Occurs with the Greenland cryolite, and is one of the results of its alteration. The author is indebted for his knowledge of the mineral to Dr. Hagemann. The underlying material is compact thomsenolite. At the request of Dr. Hagemann, it is named by the author from γῆ, *earth*, and *arksutite*, alluding to its earthy aspect.

171. PROSOPITE. Prosopit *Scheerer*, Pogg., xc. 315, 1853, xcii., 612, ci. 361.

134



Altenberg.

Monoclinic. $I \wedge I = 115° 14'$; $i\text{-}\grave{2} \wedge i\text{-}\grave{2} = 76° 15'$, $-2 \wedge -2 = 133° 30'$, $2\text{-}\grave{\imath} \wedge 2\text{-}\grave{\imath} = 116° 30'$, $2\text{-}\grave{3} \wedge 2\text{-}\grave{3} = 120° 56'$. Only in imbedded crystals.

H.=4·5. G.=2·890—2·898. Lustre weak. Colorless, white, or grayish.

Comp.—Analysis by Scheerer (Pogg., ci. 361, 385):

	Si F^2	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
Altenberg	10·71	42·68	0·31	0·25	22·98	0·15	15·50=92·58.

The loss of 7·42 p. c. is regarded by Scheerer as proving that 5·50 p. c. of the oxygen is replaced by fluorine; the mineral is thence regarded by him as consisting of $\frac{3}{2}$ Si F^2, 6 $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, 1 $\dot{\mathrm{C}}\mathrm{a}$, 5 Ca F, 12 $\dot{\mathrm{H}}$, or, differently arranged, $\frac{3}{2}$ Si F^2, 1 $\bar{\mathrm{A}}\mathrm{l}\,\mathrm{F}^3$, 5 $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, 2 Ca F, 4 $\dot{\mathrm{C}}\mathrm{a}$, 12 $\dot{\mathrm{H}}$.

Pyr., etc.—In the glass tube affords water and fluorid of silicon. Decomposable by sulphuric acid.

Obs.—Occurs at the tin mines of Altenberg, in crystals, part of which are a kind of kaolin, and others, according to observations by G. J. Brush (Am. J. Sci., II. xxv. 411), cleavable violet fluor, and others still fluor partly kaolinized.

Also found at the Schlackenwald tin mines; but Scheerer infers, without an analysis, that the crystals from this place (Pogg., xcii. 612) are a phosphate with fluorid, and he gives the hypothetical formula ($\dot{\mathrm{R}}^3\,\dddot{\mathrm{P}}$, R F) Al F^3+y$\dot{\mathrm{H}}$.

The crystals are closely like datolite in form, as shown by the author in the last edition of this work (p. 502). Descloizeaux has stated that *optically* they are triclinic.

It is yet doubtful whether unaltered prosopite has been described or seen.

Named from προσωπεῖον, a mask, in allusion to the deceptive character of the mineral.

V. OXYGEN COMPOUNDS.

The grand divisions of Oxygen Compounds among minerals are mentioned on page 1.

I. OXYDS.

General Arrangement.

1. **Oxyds of Elements of Series I.**

   a. Anhydrous.
   b. Hydrous.

2. **Oxyds of Elements of the Arsenic and Sulphur Groups, Series II.**

3. **Oxyds of Elements of the Carbon-Silicon Group, Series II.**

---

1. OXYDS OF ELEMENTS OF SERIES I.

A. ANHYDROUS OXYDS.

The elements of Series I. whose oxyds are here included are those of the iron and tin groups, none of the gold group occurring native. The oxyds have, with few exceptions, the general formulas $\bar{R}O$, RO, R^2O^3, $RO+R^2O^3$, and RO^2.

Isometric forms occur under the formulas $\bar{R}O$; RO; $RO+R^2O^3$.
Hexagonal " " RO; R^2O^3.
Tetragonal " " RO^2; $2RO+RO^2$.
Orthorhombic " " RO; $RO+R^2O^3$; RO^2

The following are the groups of Anhydrous Oxyds:

1. PROTOXYDS—$\bar{R}O$, RO.

1. CUPRITE AND PERICLASITE GROUPS.—Isometric.

172. **Cuprite**	$\dot{\bar{C}}u$	174. **Bunsenite**	$\dot{N}i$
173. **Periclasite**	$\dot{M}g$		

2. ZINCITE GROUP.—Hexagonal.

175.	**Water**	$\dot{\mathrm{H}}$	176.	**Zincite**	$\dot{\mathrm{Zn}}$

3. MASSICOT GROUP.—Isometric and orthorhombic.

177.	**Massicot**	$\dot{\mathrm{Pb}}$	178.	**Melaconite**	$\dot{\mathrm{Cu}}$

2. SESQUIOXYDS—$R^2\,O^3$.

1. CORUNDUM GROUP.—Hexagonal.

179.	**Corundum**	$\dddot{\bar{\mathrm{Al}}}$	181.	**Menaccanite**	$(\mathrm{Fe},\ \mathrm{Ti})^2\,O^3$ or $(\mathrm{Fe},\ \mathrm{Ti})^2\,O^3 + n\,\ddot{\mathrm{Ti}}$
180.	**Hematite**	$\dddot{\bar{\mathrm{Fe}}}$	182.	**Perofskite**	$(\mathrm{Ca},\ \mathrm{Ti})^2\,O^3$

3. COMPOUNDS OF PROTOXYDS AND SESQUIOXYDS—In the ratio 1 : 1, or $R\,O + R^2\,O^3$

1. SPINEL GROUP.—Isometric.

183.	**Spinel**	$\dot{\mathrm{Mg}}\,(\dddot{\bar{\mathrm{Al}}},\ \dddot{\bar{\mathrm{Fe}}})$	187.	**Magnesioferrite**	$\dot{\mathrm{Mg}}\,\dddot{\bar{\mathrm{Fe}}}$
184.	**Hercynite**	$\dot{\mathrm{Fe}}\,\dddot{\bar{\mathrm{Al}}}$	188.	**Franklinite**	$(\dot{\mathrm{Zn}},\ \dot{\mathrm{Fe}},\ \dot{\mathrm{Mn}})\,(\dddot{\bar{\mathrm{Fe}}},\ \dddot{\bar{\mathrm{Mn}}})$
185.	**Gahnite**	$(\dot{\mathrm{Zn}},\ \dot{\mathrm{Fe}},\ \dot{\mathrm{Mg}})\,(\dddot{\bar{\mathrm{Al}}},\ \dddot{\bar{\mathrm{Fe}}})$	189.	**Chromite**	$(\dot{\mathrm{Fe}},\ \dot{\mathrm{Mg}},\ \dot{\mathrm{Cr}})\,(\dddot{\bar{\mathrm{Al}}},\ \dddot{\bar{\mathrm{Fe}}},\ \dddot{\bar{\mathrm{Cr}}})$
186.	**Magnetite**	$\dot{\mathrm{Fe}}\,\dddot{\bar{\mathrm{Fe}}}$	190.	**Uraninite**	$?\,\dot{\mathrm{U}}\,\dddot{\bar{\mathrm{U}}}$

2. CHRYSOBERYL GROUP.—Orthorhombic.

191.	**Chrysoberyl**	$\dot{\mathrm{Be}}^3\,\dddot{\bar{\mathrm{Al}}}$

4. DEUTOXYDS—$R\,O^2$.

1. RUTILE GROUP.—Tetragonal.

192.	**Cassiterite**	$\ddot{\mathrm{Sn}}$	195.	**Hausmannite**	$\dot{\mathrm{Mn}}^2,\ \ddot{\mathrm{Mn}}$
193.	**Rutile**	$\ddot{\mathrm{Ti}}$	196.	**Braunite**	$2\,\dot{\mathrm{Mn}}^3\,\dddot{\bar{\mathrm{Mn}}} + \dddot{\bar{\mathrm{Mn}}}\,\dddot{\mathrm{Si}}$
194.	**Octahedrite**	$\ddot{\mathrm{Ti}}$	197.	? **Minium**	$\dot{\mathrm{Pb}}^2\,\ddot{\mathrm{Pb}}$

2. BROOKITE GROUP.—Orthorhombic.

198.	**Brookite**	$\ddot{\mathrm{Ti}}$	199.	**Pyrolusite**	$\ddot{\mathrm{Mn}}$

5. COMPOUNDS OF PROTOXYDS AND SESQUIOXYDS—In the ratio 3 : n, or $3\,RO + n\,R^2O^3$.

300. **Crednerite** (Monoclinic) $\dot{\mathrm{Cu}}^3\,\dddot{\bar{\mathrm{Mn}}}^2$

Appendix. 201. **Plattnerite.**

Some points in the above table require explanation. Admitting the principle stated on page 33, that in oxyds crystallizing in the *hexagonal* system the number of atoms of the *negative* element, oxygen, is 3, or a multiple of 3; and that in those crystallizing in the *tetragonal* system this number is 2 or 4, or a multiple of 4; and that the sesquioxyds $Fe^2\,O^3$, $Al^2\,O^3$ are hexagonal species in accordance with this principle, and the deutoxyds $Ti\,O^2$, $Sn\,O^2$ are tetragonal in exemplification of it,* we have reasons for the following conclusions. In the Zincite group, since water (ice) and zincite are hexagonal, these species, *when thus crystallized* (whatever be true in other states), may have the formulas $H^3\,O^3$, and $Zn^3\,O^3$. In the Massicot group, since the two species mentioned occur both in isometric and orthorhombic forms; and since the orthorhombic form is in angle closely like that of orthorhombic $\mathrm{Ti\,O^2}$ (brookite), the angles $I \wedge I$ and $I \wedge \frac{1}{2}$ being 99° 39′, 126° 29′ in cuprite, and 99° 50, 126° 15′ in brookite, it would seem to be true that while the isometric kinds have the formulas $\mathrm{Pb\,O}$ and $\mathrm{Cu\,O}$, as ordinarily written, the orthorhombic have the formulas $\mathrm{Pb^2\,O^2}$ and $\mathrm{Cu^2\,O^2}$ (or $\bar{\mathrm{C}}\mathrm{u\,O^2}$); and that the latter ought to be arranged with the deutoxyds, in the same group with brookite, which also has 2 of oxygen. (This arrangement would have been adopted above, if distinct orthorhombic forms of the species had been observed in nature.)

---

* The principle does not require that when the number of atoms of oxygen is 2 or 4, or a multiple of 4, that the forms should be *necessarily* tetragonal, but recognizes that tetragonal forms are then ble. The oxyd $Ti\,O^2$ crystallizes not only in tetragonal forms, but also in orthorhombic.

Again, under the Rutile group are arranged the species hausmannite and braunite, ores of manganese. The formula of *hausmannite* is commonly written $\dot{\mathrm{M}}\mathrm{n}\ \dddot{\mathrm{M}}\mathrm{n}$, making it analogous to species of the Spinel group. But it accords better with its tetragonal crystallization and its relations to $\mathrm{Ti\,O^2}$, to write it $\dot{\mathrm{M}}\mathrm{n}^2\ \ddot{\mathrm{M}}\mathrm{n}$. *Braunite* has been shown by Rammelsberg to have a composition that may be represented by the formula $(\mathrm{Mn\,Si})^2\,\mathrm{O^3}$, in which Mn and Si appear as replacing one another. The constituents, as deduced by analysts, are $3\,\dddot{\mathrm{M}}\mathrm{n} + \dot{\mathrm{M}}\mathrm{n} + \ddot{\mathrm{S}}\mathrm{i}$, which include 8 of Mn and Si to 12 of oxygen, in accordance with the above formula. But braunite has closely the crystallization of $\mathrm{Ti\,O^2}$ in rutile; and this relation is brought out in the formula $2\,\dot{\mathrm{M}}\mathrm{n}^2\ \ddot{\mathrm{M}}\mathrm{n} + \dot{\mathrm{M}}\mathrm{n}\ \ddot{\mathrm{S}}\mathrm{i}$ above given, which represents it as corresponding to 2 of hausmannite and 2 of a silicate analogous to zircon, with which silicate also it is isomorphous. The close relation and isomorphism of Mn and Si assumed in the formula $(\mathrm{Mn,\,Si})^2\,\mathrm{O^3}$ is unsustained by facts.

---

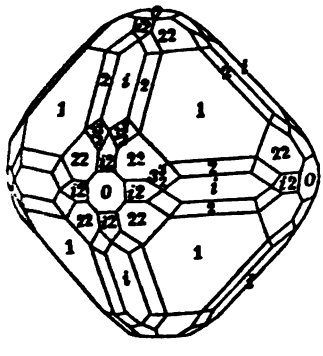
1. PROTOXYDS.

172. CUPRITE. Aes caldarium rubro-fuscum, *Germ.* Lebererzkupfer, *Agric.*, Foss., 334, Interpr., 462, 1546. Minera cupri calciformis pura et indurata, colore rubro, vulgo Kupferglas, Kupfer Lebererz., *Cronst.*, Min., 173, 1758. Cuprum tessulatum nudum *Linn.*, Syst., 172, tab. viii., 1756; Cuprum cryst. octaëdrum *ib.*, 1768. Octahedral Copper Ore, Red Glassy Copper Ore, *Hill*, Foss., 1771. Mine rouge de cuivre *Sage*, Min., 1772. Mine de cuivre vitreuse rouge *de Lisle*, Crist., 1772, 1783. Rothkupfererz. Cuivre oxidulé. Oxydulated copper. Zigueline *Beud.*, Tr., ii. 718, 1832. Ruberite *Chapm.*, Pract. Min., 63, 1843. Cuprit *Haid.*, Handb., 548. 1845.

Ziegelerz=Tile Ore; Kupferlebererz; Hepatinerz.

Haarformiges Rothkupfererz; Cuivre oxidulé capillaire, *H.*; Kupferblüthe *Hausm.*; Capillary Red Oxyd of Copper. Chalkotrichit *Glock.*, Grundr., 869, 1839.

135



Isometric. Observed planes, *O*, 1, *i*, *i*-2 (e′), *i*-5, 2 (a″), 3, 2-2 (a′), 3-$\frac{3}{2}$ (o). Figs. 1 to 8, and f. 135. Cleavage: octahedral. Sometimes cubes lengthened into capillary forms. Also massive, granular; sometimes earthy.

H.=3·5—4. G.=5·85—6·15; 5·992, Haidinger. Lustre adamantine or submetallic to earthy. Color red, of various shades, particularly cochineal-red; occasionally crimson-red by transmitted light. Streak several shades of brownish-red, shining. Subtransparent—subtranslucent. Fracture conchoidal, uneven. Brittle.

Comp., Var.—Oxyd of copper, $\dot{\bar{\mathrm{C}}}\mathrm{u}$=Oxygen 11·2, copper 88·8=100. Sometimes affords traces of selenium.

Var. 1. *Ordinary* (*a*) Crystallized; commonly in octahedrons, dodecahedrons, cubes, and intermediate forms; the crystals often with a crust of malachite; (*b*) massive.

2. *Capillary*; *Chalcotrichite.* In capillary or acicular crystallizations, supposed formerly to be orthorhombic, but, according to Brooke and A. Knop, really cubes elongated in the direction of the octahedral axis (Knop, Jahrb. Min., 521, 1861).

3. *Earthy; Tile Ore* (Ziegelerz *Germ.*). Brick-red or reddish-brown and earthy, often mixed with red oxyd of iron; sometimes nearly black.

The *hepatinerz*, or *liver-ore*, of Breithaupt has a liver-brown color. Von Bibra found (J. pr. Ch. xcvi. 203) the tile-ore of Algodon bay, Bolivia, to contain chlorine, and to be a mixture of atacamite, cuprite, hematite, and other earthy material; he obtained for one, atacamite 31·32, cuprite 10·85, sesquioxyd of iron 20·50, gangue 34·42, water, antimony, and loss 2·87. In two others, atacamite 28·40, 33·25, cuprite 12·77, 13·02, limonite 25·00, 19·07, gangue 30·81, 32·57, water, antimony and loss 3·02, 2·09.

Pyr., etc.—Unaltered in the closed tube. B.B. in the forceps fuses and colors the flame emerald-green; if previously moistened with muriatic acid, the color imparted to the flame is momentarily azure-blue from chlorid of copper. On charcoal first blackens, then fuses, and is reduced to metallic copper. With the fluxes gives reactions for oxyd of copper. Soluble in concentrated muriatic acid.

Obs.—Occurs at Camsdorf and Saalfield in Thuringia, at Les Capanne Vecchie in Tuscany; on Elba, in cubes; in Cornwall, in fine translucent crystals with native copper and quartz, at Wheal Gorland and other Cornish mines; in Devonshire near Tavistock; in isolated crystals, sometimes an inch in diameter, in lithomarge, at Chessy, near Lyons, which are generally coated with malachite; at Katherinenberg in Siberia; in South Australia; also abundant in Chili, Peru, Bolivia, the crystals in which regions, as far as examined by D. Forbes, are simple cubes (private communication); very fine crystals from Andacollo near Coquimbo.

It has been observed at Schuyler's, Somerville, and Flemington copper mines, N. J., crystallized and massive, associated with chrysocolla and native copper; also near New Brunswick, N. J., in red shale; 2 m. from Ladenton, Rockland Co., N. Y., with green malachite in trap; at Cornwall, Lebanon Co., Pa.; in the Lake Superior region.

When found in large quantities this species is valuable as an ore of copper.

Named *cuprite* by Haidinger from the Latin *cuprum*, *copper*. Chapman's name *ruberite* (from the Latin *ruber*, *red*) is prior in date (l. c.); but the laws of derivation would change it to *rubrite*; and instead of introducing this altered name, that next in priority, already long used, is here adopted.

Alt.—A deoxydation of this oxyd of copper sometimes takes place, producing native copper. It also becomes carbonated and green, by means of carbonated waters, changing to malachite or azurite; or through a silicate in solution it is changed to chrysocolla; or by taking oxygen it becomes melaconite. Limonite occurs as a pseudomorph by substitution after cuprite.

173. PERICLASITE. Periclasia *Scacchi*, Mem. Min., Naples, 1841. Periklas *Germ.*

Isometric. Figs. 1, 2. Cleavage: cubic, perfect. Also in grains.

H.= nearly 6. G. = 3·674, Damour. Color grayish to dark-green. Transparent to translucent.

Comp.—$\dot{M}g$; or magnesia, with 1 part in 25 of protoxyd of iron. Analyses: 1, Scacchi (l. c.); 2, 3, Damour (Ann. d. M., IV. iii. 360, and Bull. Soc. G. Fr., 1849, 313):

1.	$\dot{M}g$ 89·04	$\dot{F}e$ 8·56=97·60	Scacchi.
2.	93·86	5·97=99·83	Damour.
3.	93·38	6·01=99·39	Damour.

Pyr., etc.—B.B. unaltered and infusible. With cobalt solution after long blowing assumes a faint flesh-red color. The pulverized mineral shows an alkaline reaction when moistened, and dissolves in mineral acids without effervescence.

Obs.—Occurs disseminated through ejected masses of a white limestone, and in spots of small clustered crystals, on Mt. Somma, sometimes with forsterite and earthy magnesite.

Named from περι, *about*, and κλάσις, *cleavage*.

Artif.—Formed in crystals of a cubo-octahedral form by making lime to act at a high temperature on borate of magnesia (Ebelmen); by the action of chorhydric gas on magnesia (Deville); by the action of chlorid of magnesium on lime (Daubrée).

174. BUNSENITE. Nickeloxydul *C. Bergemann*, J. pr. Ch., lxxv. 243, 1858. Protoxyd of Nickel. Bunsenite *Dana*.

Isometric. In octahedrons, sometimes having truncated edges.

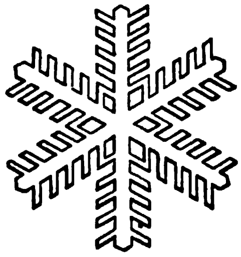
H.=5·5. G.=6·398. Lustre vitreous. Color pistachio-green. Streak brownish-black. Translucent. [Characters of minute crystals half a line in diameter.] Artificial crystals observed in slags have a metallic lustre, and brownish-black color.

Comp.—Ṅi, or pure protoxyd of nickel.

Obs.—Occurs in cavities with other nickel ores, and ores of uranium, at Johanngeorgenstadt (C. Bergemann, J. pr. Ch., lxxv. 239).

Named after Prof. Bunsen, who observed long since artificial crystals of this oxyd of nickel.

175. WATER



136

Hexagonal. Usual in compound stellate forms, one form of which is shown in f. 136.

G.=0·918, Brunner; 0·9178 at 32° F., L. Dufour. Colorless. Inodorous. Tasteless. Liquid above 32° F., and boils at 212° F. A cubic inch of pure water at 60° F., and 30 inches of the barometer, weighs 252·458 grains.

Comp.—HO=Oxygen 88·89, hydrogen 11·11=100.

Obs.—The density of water is greatest at 39°·1 F., according to Joule and Playfair. Despretz obtained 39°·176; Hallström 39°·38; Blagden and Gilpin 39°; Hope 39°·5; Muncke 38°·804. Below this temperature it expands as it approaches 32°, owing to incipient crystallization.

Water as it occurs in nature is seldom pure. It ordinarily contains some atmospheric air, often pure oxygen and carbonic acid, besides various saline ingredients, as salts of magnesia, lime, iron, soda, potash, and sometimes traces of zinc, arsenic, lead, copper, antimony, and even tin, these ingredients being derived from the rocks or soil of the region. For citation of numerous recent analyses of waters, see Kenngott's Uebersicht, 1844–1862; also the Jahresbericht f. Ch., etc.

Obs.—See on the Crystallization of Ice, Leydolt, Ber. Ak. Wien., vii. 477. Also A. E. Nordenskiöld, who states that it is dimorphous; one form probably orthorhombic (J. pr. Ch., lxxxv. 431).

176. ZINCITE. Red Oxyd of Zinc *A. Bruce*, Bruce's Min. J., i., No. 2, 96, 1810. Zinkoxyd, Rothzinkerz, *Germ.* Zinc oxydé *Fr.* Red Zinc Ore. Zinkit *Haid.*, Handb., 548, 1845. Spartalite *B. & M.*, 218, 1852. Sterlingite F. Alger, Min., 565, 1844.

Hexagonal. *O* ∧ 1=118° 7′; *a*=1·6208. In quartzoids with truncated summits, and prismatic faces *I*. 1 ∧ 1=127° 40′ (to 43′), Rose; *I* ∧ 1=151° 53′; 152° 20′, Levy. Cleavage: basal, eminent; prismatic, sometimes distinct. Usual in foliated grains or coarse particles and masses; also granular.

H.=4–4·5. G.=5·43–5·7. 5·684, orange-yellow crystals, W. P. Blake. Lustre subadamantine. Streak orange-yellow. Color deep red, also orange-yellow. Translucent—subtranslucent. Fracture subconchoidal. Brittle.

Comp.—Żn=Oxygen 19·74, zinc 80·26=100; containing oxyd of manganese as an unessential ingredient. Analyses: 1, Bruce (l. c.); 2, Berthier (Ann. d. M., iv. 483); 3, 4, Whitney (Pogg., lxxi. 169); 5, A. A. Hayes (Am. J. Sci., xlviii. 261); 6, W. P. Blake (Mining Mag., II. ii. 94, 1860):

	Żn	Mn	M̶n	F̶e	
1. *Red*	92	——	8		=100 Bruce.
2. "	88		12	——	=100 Berthier.
3. "	94·45	——	*tr.*	——	, Frankl. 4·49, ign. 1·09=100·03 Whit.
4. "	96·19	——	3·70	——	, *undec.* 0·10=99·99 Whitney.
5. "	93·48	5·50	——	0·36	, scales F̶e 0·44=99·78 Hayes.
6. *Yellow*	99·47	——	0·68	——	, ign. 0·23=100·38 Blake.

Thin scales magnified and viewed by transmitted light are deep yellow. The author finds by means of a high magnifying power that this ore is free from foreign scales of red oxyd of iron or other substances; and consequently the color is probably due, as held by G. Rose and J. D Whitney, to the presence of $\dot{M}n$. The crystals analyzed by Blake (anal. 6), which contain less than 1 p. c. of $\dot{M}n$, were orange-yellow in color.

Pyr., etc.—Heated in the closed tube blackens, but on cooling resumes the original color. B.B. infusible; with the fluxes, on the platinum wire, gives reactions for manganese, and on charcoal in R.F. gives a coating of oxyd of zinc, yellow while hot, and white on cooling. The coating moistened with cobalt solution and treated in R.F., assumes a green color. Soluble in acids without effervescence. On exposure to the air it suffers a partial decomposition at the surface and becomes invested with a white coating, which is carbonate of zinc.

Obs.—Occurs with Franklinite and also with calcite at Stirling Hill and Mine Hill, Sussex Co., N. J., sometimes in lamellar masses in pink calcite. It was first noticed, described, and analyzed, by Dr. Bruce. Reported as forming pseudomorphs after blende at Schneeberg.

An oxyd of zinc, mixed with hydrate of iron, occurs on marmatite at Bottino in Tuscany, which afforded C. Bechi (Am. J. Sci., II. xiv. 62) $\dot{Z}n$ 31·725, $\not{F}e$ 47·450, $\dot{H}$ 20·825.

Artif.—Mitscherlich has observed minute six-sided prisms in the iron furnaces of Königshütte in Silesia. Similar crystals have been met with in the zinc furnaces near Siegen; also in the furnaces and roast-heaps at the New Jersey zinc mines; surface drusy, color white to amber-yellow (Am. J. Sci., II. xiii. 417); in hexagonal prisms in the zinc furnaces at Bethlehem, Pa., and Newark, N. J.; by L. Stadtmuller at the iron furnace of Van Deusenville, Mass.; also at other furnaces in Europe and America.

177. MASSICOT. Bleiglätte. Lead-ochre. Plumbic Ochre. Oxyd of Lead. Plomb oxidé.

Massicot *Huot*, Min., 346, 1841.

Orthorhombic and isometric (artif.). Massive; structure scaly crystalline, or earthy.

H.=2. G.=8·0; 7·83—7·98, from Mexico, Pugh; 9·2—9·36 when pure. Lustre dull. Color between sulphur and orpiment-yellow, sometimes reddish. Streak lighter than the color. Opaque. Does not soil.

Comp.—$\dot{P}b$=Oxygen 7·17, lead 92·83=100; more or less impure. **Analyses**: 1, John (Schw. J., iv. 219, xxxii. 106); 2, 3, Pugh (Ann. Ch. Pharm., c. 128):

	$\dot{P}b$	$\ddot{C}$	$\not{F}e$, $\dot{C}a$	$\ddot{S}i$
1.	89·10	3·84	0·48	2·40=95·82 John.
2. Mexico	92·91	1·38	$\not{F}e$ 5·57	tr., S and loss 0·14 Pugh.
3. "	92·40	1 38	" 4·85	0·14, " 1·23 Pugh.

The specimens analyzed by Pugh were from the mine of Guillermo, near Perote, in the district of Vera Cruz, where native lead also is reported to occur in galena.

Pyr., etc.—B.B. fuses readily to a yellow glass, and on charcoal is easily reduced to metallic lead.

Obs.—It is said to occur at Badenweiler in Baden, in quartz. Gerolt states that it has been ejected from the volcanoes of Popocatapetl and Jztaccituall, in Mexico. It is found in many places in the provinces of Chihuahua and Cohahuila in considerable quantities, having been collected along the streams between Ceralvo and Monterey, being supposed to come from the range of mountains running nearly north of Monterey. The specimens (often 2 or more cubic inches in size) are between orpiment and sulphur-yellow in color, and glisten like a granular mica of a nearly golden color. The natural surface is slightly crystalline and shining, and when broken it shows a scaly texture (Bailey in Am. J. Sci., II. viii. 420).

Occurs also at Austin's mines, Wythe Co., Va.

Artif.—Artificial crystals have been obtained among furnace products and by direct chemical methods, as well as from fusion, which were orthorhombic (rhombic octahedrons, etc.); and others that were isometric (cubes, dodecahedrons, etc.).

178. MELACONITE. Kupferschwärze *Wern.*, Bergm. J., 1789. Black Oxyd of Copper; Black Copper. Melaconite *Huot*, Min., 326, 1841. Tenorite *Semmola*, Opere Minori, 45, Napoli, 1841, Bull. G. Fr., xiii. 206, 1841-42. Melaconisa *A. Scacchi*, Distrib. Sist. Min., 40, Napoli, 1842. Melaconite *Dana*, Min., 518, 1850.

isometric and orthorhombic (artif.). Earthy; massive; pulverulent; also in shining flexible scales. Rarely in cubes with truncated angles (pseudomorphous ?).

H.=3. G.=6·25, massive, Whitney; 5·952, ib., Joy. Lustre metallic, and color steel or iron-gray when in thin scales; dull and earthy, with a black or grayish-black color, and ordinarily soiling the fingers when massive or pulverulent.

Var.—1. Earthy-black, sometimes under the forms of crystals. 2. In scales, with a metallic lustre.

Comp.—Cu O, or Ɵu O^2 (the latter for the orthorhombic)=Oxygen 20·15, copper 79·85=100. Analyses: 1, 2, Joy (Pogg., lxxx. 287); 3, id. (Ann. Lyc. N. Y., viii. 121):

	$\dot{\mathrm{Cu}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dddot{\mathrm{Si}}$
1. Copper Harbor	99·45	——	——	——=99·45 Joy.
2. " "	[95·20]	1·19	0·23	3·38=100 Joy.
3. " "	93·06	1·07	0·22	3·08=97·43 Joy.

Pyr., etc.—B.B. in O.F. infusible; other reactions as for cuprite (p. 134). Soluble in muriatic and nitric acids.

Obs.—Found on lava at Vesuvius in scales from a twentieth to a third of an inch across, often hexagonal and sometimes triangular (Semmola); and also pulverulent (Sacchi, who uses the name melaconise for the mineral). Common in the earthy form about copper mines, as a result of the decomposition of chalcopyrite and other copper ores. Abundant thus at the Ducktown mines in Tennessee, and also formerly at Copper Harbor, Keweenaw Point, L. Superior. At the latter place a vein afforded, some years since, 40,000 lbs. of this ore. Imbedded in its mass there were numerous perfect crystals, having the form of cubes with truncated angles. These crystals have been regarded as pseudomorphs after cuprite by Teschemacher, Hayes, and others. J. D. Whitney has pronounced them (Rep. L. Sup., ii. 99) original crystals of the species, on the ground that the red copper now in the vein occurs only in octahedrons.

Artif.—Becquerel obtained tetrahedral crystals by fusing oxyd of copper with potash (Ann. Ch. Phys., li. 102); and Jenzsch has described (Pogg., cvii. 647) orthorhombic crystals, found in the hearth of a calcining furnace at Freiberg, having $I \wedge I=99° 39'$, $I \wedge \frac{1}{2}=126° 29'$, $I \wedge 1\text{-}\breve{i}=122° 58'$, $I \wedge 1\text{-}\bar{i}=113° 58'$, approaching the angles of brookite, and showing a relation of this oxyd of copper to the deutoxyds; $I \wedge I$ in brookite being 99° 50′, and $I \wedge \frac{1}{2}=126° 15'$.

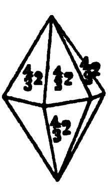
Marcylite Shepard (Marcy's Expl. Red River, 135, 1854, Shep. Min., 1857, 405) is an uncertain mixture from the Red River, near the Wachita Mts., Arkansas. Shepard made it (l. c.) a mixed hydrous chlorid and oxyd of copper, as if containing atacamite. Specimens put by him into the hands of S. W. Tyler for analysis were found to contain (Am. J. Sci., II. xli. 111) 63·42 p. c. of copper and 17·22 of sulphur, with a "supposed" amount of oxygen and water set down at 8 of oxygen and 9 of water, whence it is supposed to consist of oxyd of copper (Cu O) 39·70, sulphid of copper (Cu S) 47·70, with 9 of water. It is evidently a result of the alteration of a sulphid of copper.

2. SESQUIOXYDS.

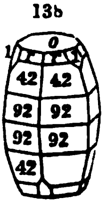
179. CORUNDUM. Corindon (=Sapphire, Corundum, and Emery united) *H.*, Gilb. Ann., xx. 187, 1805, Lucas Tabl., i. 257, 1806.

Rhombohedral. $R \wedge R=86° 4'$, $O \wedge 1(R)=122° 26'$; (122° 25′, Kokscharof); $a=1·363$. Observed planes: rhombohedrons, $\frac{1}{3}$, $\frac{1}{2}$, $1(R)$, -2, -1; pyramids, $\frac{4}{3}$-2 (f. 137, 139, 140, and plane *r* in f. 138), $\frac{14}{9}$-2, 2-2, $\frac{8}{3}$-2, $\frac{10}{3}$-2, 4-2, $\frac{16}{3}$-2, 8-2, 9-2; scalenohedrons, $\frac{2}{3}^{\frac{5}{3}}$, $\frac{2}{5}^{3}$, $\frac{1}{4}^{5}$ (=$\frac{10}{9}$-$\frac{5}{4}$, $\frac{6}{5}$-$\frac{3}{2}$, $\frac{5}{4}$-$\frac{5}{3}$); also *I*, *i*-2, *i*-$\frac{4}{3}$, *O*.

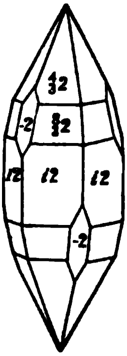
137



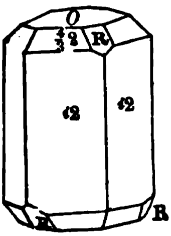
138



140



139



$O \wedge \frac{1}{3} = 152° 19'$
$O \wedge \frac{1}{2} = 141\ 48$
$O \wedge 2 = 107\ 38$
$O \wedge 2\text{-}2 = 110\ 9$

$i\text{-}2 \wedge \frac{4}{3}\text{-}2 = 151\ 11$
$2 \wedge 2 = 78\ 45$

Cleavage: basal, sometimes perfect, but interrupted, commonly imperfect in the blue variety; also rhombohedral. Large crystals usually rough. Twins: composition-face *R*. Also massive granular or impalpable; often in layers from composition parallel to *R*.

H.=9. G.=3·909—4·16. Lustre vitreous; sometimes pearly on the basal planes, and occasionally exhibiting a bright opalescent star of six rays in the direction of the axis. Color blue, red, yellow, brown, gray, and nearly white; streak uncolored. Transparent—translucent. Fracture conchoidal—uneven. Exceedingly tough when compact.

Comp., Var.—Pure alumina $\overset{\cdots}{\text{Al}}$=Oxygen 46·6, aluminum 53·4=100.

There are three subdivisions of the species prominently recognized in the arts, and until early in this century regarded as distinct species; but which actually differ only in purity and state of crystallization or structure. Haüy first (in 1805) formally united them under the name here accepted for the species, though the fact that adamantine spar and sapphire were alike in crystallization did not escape the early crystallographer Romé de Lisle, and led him to suggest their identity.

VAR. 1. SAPPHIRE.—'Υάκινθος (bluish S.) *Gr.*; Hyacinthos (id.) *Plin.*, xxxvii. 44; Asteria (the asteriated) *id.*, xxxvii. 49. Jacut *Arab.* [fr. name in India, and thence Hyacinthus *Vet.* (?) King]. 'Ανθραξ (red S., the Greek meaning *burning coal*) pt., *Theophr.* Carbunculus, Lychnis (red S.), pt. *Plin.*, xxxvii. 25, 29. Saphir, Sapphirus, *Wall.*, Min., 116; Orientalisk Rubin, id., 117, 1747. Télésie *H.*, Tr., 1801. Corindon hyalin *H.*, 1805.

Includes the purer kinds of fine colors, transparent to translucent, useful as gems. Stones are named according to their colors; true *Ruby*, or *Oriental Ruby*, red; *O. Topas*, yellow; *O. Emerald*, green; *O. Amethyst*, purple. A variety having a stellate opalescence when viewed in the direction of the vertical axis of the crystal, is the *Asteriated* Sapphire (*Asteria* of Pliny). The ruby sapphire was probably included under the ἄνθραξ of Theophrastus, and the *Carbunculus* and *Lychnis* of Pliny.

2. CORUNDUM.—Adamas Siderites *Plin.*, xxxvii. 15. Karund *Hind.* Corivindum, Corivendum (fr. India), *Woodw.*, Cat. Foss., 1714, 1725. Adamantine Spar (fr. India) *Black*, 178–? according to Greville and Klaproth (v. seq.). Demantspath *Klapr.*, Mem. Acad., Berlin, 1786–87, Berlin. 1792; Beitr., i. 47, 1795; *Wern.*, Bergm. J., i. 875, 390, 1789. Spath adamantin *Delameth.*, J. de Phys., xxx. 12, 1787; *Haüy*, ib., 193. Corundum *Greville*, Phil. Trans., 1798. Corindon *H.*, Tr., 1801. Corindon harmophane *H.* Corindon adamantin *Brongn.*, Min., i. 429, 1807. Korund *Germ.*

Includes the kinds of dark or dull colors and not transparent, colors light blue to gray, brown, and black. The original adamantine spar from India has a dark grayish smoky-brown tint, but greenish or bluish by transmitted light, when translucent, and either in distinct crystals often large, or cleavable-massive. It is ground and used as a polishing material, and being purer, is superior in this respect to emery. It was thus employed in ancient times, both in India and Europe. The "Armenian stone" below is supposed by King to have been corundum rather than emery.

3. EMERY.—'Ακόνη ἐξ 'Αρμενίας [=Armenian Whetstone], *Theophr.* Σμύρις *Dioscor.*, v. 165 Naxium (fr. Naxos), Naxium ex Armenia, *Plin.*, xxxvi. 10. Pyrites vivus (?) *Plin.*, xxxvi. 30

myra, Smiris, *Agric.*, Foss., 1546. Smergel, Smiris ferrea, *Wall.*, Min. 267, 1747. Smirgel, Schmirgel, *Germ.* Emeril *H.*, Tr., 1801; Corindon granuleux *H.*, 1805.

Includes granular corundum, of black or grayish-black color, and contains magnetite or hematite intimately mixed. Feels and looks much like a black fine-grained iron ore, which it was long considered. There are gradations from the evenly fine-grained emery to kinds in which the corundum is in distinct crystals. This last is the case with part of that at Chestor, Massachusetts

The following are analyses by J. Lawrence Smith, taken from elaborate papers in the Am. J. Sci., II. x. 354, xi. 53, xlii. 83. The column of hardness gives the effective abrasive power of the powdered mineral, that of sapphire being 100; Mag. stands for *Magnetite:*

Dr. C. T. Jackson makes the formula of emery $\dot{\mathrm{F}}\mathrm{e}\ \ddot{\bar{\mathrm{A}}}\mathrm{l}$, and puts the mineral in the spinel family. But neither microscopic nor chemical investigations appear to sustain this view.

Pyr., etc.—B.B. unaltered; slowly dissolved in borax and salt of phosphorus to a clear glass, which is colorless when free from iron; not acted upon by soda. The finely pulverized mineral, after long heating with cobalt solution, gives a beautiful blue color. Not acted upon by acids, but converted into a soluble compound by fusion with bisulphate of potash or soda. Friction excites electricity, and in polished specimens the electrical attraction continues for a considerable length of time.

Obs.—This species is associated with crystalline rocks, as granular limestone or dolomite gneiss, granite, mica slate, chlorite slate. The fine sapphires are usually obtained from the beds of rivers, either in modified hexagonal prisms or in rolled masses, accompanied by grains of magnetic iron ore, and several species of gems. The emery of Asia Minor, according to Dr. Smith, occurs in granular limestone.

The best ruby sapphires occur in the Capelan mountains, near Syrian. a city of Pegu, and in the kingdom of Ava; smaller individuals occur near Bilin and Merowitz in Bohemia, and in the sand of the Expailly river in Auvergne. Blue sapphires are brought from Ceylon; this variety was called *Salamstein* by Werner. Corundum occurs in the Carnatic on the Malabar coast, in the territories of Ava, and elsewhere in the East Indies; also near Canton, China. At St. Gothard, it occurs of a red or blue tinge in dolomite. and near Mozzo in Piedmont, in white compact feldspar. Adamantine spar is met with in large coarse hexagonal pyramids on the Malabar coast, and in Gellivara, Sweden. Emery is found in large boulders at Naxos, Nicaria, and Samos of the Grecian islands; also in Asia Minor, 12 m. E. of Ephesus, near Gumuch-dagh, where it was discovered in situ by Dr. J. Lawrence Smith, associated with margarite, chloritoid, pyrite, calcite, etc.; and also at Kulah, Adula, and Manser, the last 24 m. N. of Smyrna; also with the nacrite (?) of Cumberland, England. Other localities are in Bohemia near Petschau; in the Ural, near Katharinenburg; and in the Ilmen mountains, not far from Miask; Frederick Valley, Australia.

In N. America, in *Maine*, at Greenwood, in cryst. in mica schist, with beryl, zircon, lepidolite, rare. In *Massachusetts*, at Chester, corundum and emery in a large and valuable vein, consisting mainly of emery and magnetite, associated with diaspore, ripidolite, margarite, etc.; the corundum occasionally in blue bi-pyramidal crystals. In *Connecticut*, at W. Farms, near Litchfield, in pale blue crystals; at Norwich, with sillimanite, rare. In *New York*, at Warwick, bluish and pink, with spinel, and often in its cavities; Amity, white, blue, reddish crystals, with spinel and rutile in gran. limestone. In *New Jersey*, at Newton, blue crystals in gran. limestone, with grass green hornblende, mica, tourmaline, rare; at Vernon, near State line, red crystals, often several inches long. In *Pennsylvania*, in Delaware Co., in Aston, near Village Green, in large crystals; at Mineral Hill, in loose cryst.; in Chester Co., at Unionville, abundant in crystals, some masses weighing 4,000 lbs., and crystals occasionally 4 in. long, with tourmaline, margarite, and albite. In *N. Carolina*, in Buncombe Co., blue massive, cleavable, in a boulder; in Gaston Co., crystals and massive corundum. In *Georgia*, in Cherokee Co., red sapphire. In *California*, in Los Angeles Co., in the drift of San Francisqueto Pass. In *Canada*, at Burgess, red and blue crystals. A so-called *emery* from Arrowsic, Maine, ground and sold under this name, is nothing but massive garnet, much of it mixed with hornblende.

Red sapphire is the most highly esteemed. A crystal weighing four carats, perfect in transparency and color, has been valued at half the price of a diamond of the same size. They seldom exceed half an inch in length. Two splendid red crystals, however, having the form of the pyramidal dodecahedron, and "de la longueur du petit doigt," with a diameter of about an inch, are said to be in the possession of the king of Arracan. Transparent blue sapphires are sometimes over three inches long.

The *sapphire* of the Greek (σαπφειρος) was the lapis lazuli, which agrees with the character given it by Theophrastus, Pliny, Isidorus, and others. Pliny remarks, "Sapphirus cœruleus est cum purpura, habens pulveres aureos sparsos," particles of pyrite which are frequently disseminated through lapis lazuli, looking like gold. The ancient names applied to the species have already been given in the synonymy. See further on this subject, *King on Precious Stones*.

C. U. Shepard, after showing (Descr. of Em. of Chester, Mass., London, 1865) that the Chester emery is identical crystallographically with corundum, takes the precaution to propose the name *emerite* for emery, in case it should hereafter be established as a distinct species. But a name thus given has no claim to recognition.

Alt.—Corundum under some circumstances absorbs water and changes to diaspore; and perhaps also to the mica-like mineral margarite. It is also replaced by silica, forming quartz pseudomorphs.

Artif.—Formed in crystals by exposing to a high heat 4 pts. of borax and 1 of alumina (Ebelmen); by decomposing potash alum by charcoal (Gaudin); by subjecting in a carbon vessel fluorid of aluminum to the action of boric acid, the process yielding large rhombohedral plates (Deville & Caron); by addition to the last of fluorid of chromium, affording the red sapphire or ruby, or with less of the fluorid of chromium, blue sapphire, or with much of this chrome fluorid, a fine green kind; by action of chlorid of aluminum on lime (Daubrée).

Rhombohedral. $R \wedge R=86° 10'$, $O \wedge R=122° 30'$; $a=1{\cdot}3591$. Observed planes: rhombohedrons, $\frac{1}{16}$, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{4}{7}$, $\frac{5}{8}$, 1 (R), $\frac{5}{2}$, 4, -5, -2, $-\frac{5}{2}$, $-\frac{5}{4}$, -1, $-\frac{1}{2}$, $-\frac{2}{7}$, $-\frac{1}{4}$, $-\frac{1}{5}$, $-\frac{1}{6}$, $-\frac{1}{8}$; scalenohedrons, $\frac{1}{4}^3$, $\frac{2}{3}^3$, 1^3, $\frac{1}{4}^5$, $\frac{1}{2}^3$, $4^{\frac{11}{4}}$, $4^{\frac{3}{2}}$, $-\frac{1}{3}^3$, $-\frac{1}{2}^3$, -2^3; pyramids, $\frac{1}{3}$-2, $\frac{2}{3}$-2, $\frac{4}{3}$-2, $\frac{10}{3}$-2, 4-2; prisms I, i-2, i-$\frac{3}{2}$, i-$\frac{5}{4}$; and the basal plane O.

$O \wedge 2=107° 40'$	$2 \wedge 2=68° 47'$	$R \wedge \frac{4}{3}\text{-}2=154° 2'$
$O \wedge \frac{2}{3}\text{-}2=137\ 49$	$5 \wedge 5=61\ 34$	$R \wedge \frac{1}{4}=143\ 55$
$O \wedge \frac{4}{3}\text{-}2=118\ 53$	$\frac{1}{4} \wedge \frac{1}{4}=143\ 7$	$R \wedge i\text{-}2=136\ 55$
$O \wedge 1^3=103\ 32$	$\frac{1}{2} \wedge \frac{1}{2}=115\ 22$	$1^3 \wedge i\text{-}2=162\ 41$

Cleavage: parallel to R and O; often indistinct. Twins: composition-face R; also O (f. 145A). Also columnar—granular, botryoidal, and stalac titic shapes; also lamellar, laminæ joined parallel to *O*, and variously bent—thick or thin; also granular, friable or compact.

H.=5·5—6·5. G.=4·5—5·3; of some compact varieties, as low as 4·2. Lustre metallic and occasionally splendent; sometimes earthy. Color dark steel-gray or iron-black; in very thin particles blood-red by transmitted light; when earthy, red. Streak cherry-red or reddish-brown. Opaque, except when in very thin laminæ, which are faintly translucent and blood-red. Fracture subconchoidal, uneven. Sometimes attractable by the magnet, and occasionally even magnetipolar.

Elba.

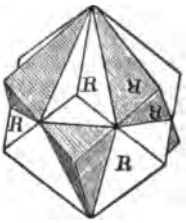
145A



Comp., Var.—Sesquioxyd of iron, $\bar{\mathrm{F}}\mathrm{e}$=Oxygen 30, iron 70=100. Sometimes containing titanium and magnesium.

In a tabular crystalline hematite from Vesuvius, Rammelsberg found (Pogg., cvii. 453) $\dot{\mathrm{F}}\mathrm{e}$ 3·11 and Mg 0·74; it was magnetic, and G.=5·303; the hematite may have contained some magnetite as impurity. Some hematite contains titanium. Crystals from Krageröe afforded Rammelsberg (Pogg., civ. 528) $\bar{\mathrm{F}}\mathrm{e}$ 93·63, $\ddot{\mathrm{T}}\mathrm{i}$ 3·55, $\dot{\mathrm{F}}\mathrm{e}$ 3·26=100·44=$\dot{\mathrm{F}}\mathrm{e}\,\ddot{\mathrm{T}}\mathrm{i}$+13 $\bar{\mathrm{F}}\mathrm{e}$, or $(\mathrm{Fe\,Ti})^2\,\mathrm{O}^3$+13 $\bar{\mathrm{F}}\mathrm{e}$.

The varieties depend on texture or state of aggregation, and in some cases the presence of impurities.

Var. 1. *Specular.* Lustre metallic, and crystals often splendent, whence the name *specular iron.* (*b*) When the structure is foliated or micaceous, the ore is called *micaceous* hematite.

2. *Compact columnar;* or fibrous. The masses often long radiating; lustre submetallic to metallic; color brownish-red to iron-black. Sometimes called *red hematite*, the name hematite among the older mineralogists including the fibrous, stalactitic, and other solid massive varieties of this species, limonite, and turgite.

3. *Red Ochreous.* Red and earthy. Often specimens of the preceding are red ochreous on some parts. *Reddle* and *red chalk* are red ochre, mixed with more or less clay.

4. *Clay Iron-stone; Argillaceous hematite.* Hard, brownish-black to reddish-brown, heavy stone; often in part deep-red; of submetallic to unmetallic lustre; and affording, like all the preceding, a red streak. It consists of oxyd of iron with clay or sand, and sometimes other impurities. (*b*) When reddish in color and jasper-like in texture, often called *jaspery* clay iron-stone. (*c*) When oolitic in structure (consisting of minute flattened concretions), it is the *lenticular iron ore.*

Itabirite is a schist resembling mica-schist, but containing much specular ore in grains or scales, or in the micaceous form.

Breithaupt states that some rhombohedrons of hematite have a magnetic axis crossing obliquely the vertical axis, passing between two opposite lateral angles (B. H. Ztg., xxv. 149); and further that the three cleavages of the rhombohedron are not quite equal.

Pyr., etc.—B.B. infusible; on charcoal in R.F. becomes magnetic; with borax in O.F. gives a bead, which is yellow while hot and colorless on cooling, if saturated, the bead appears red while hot and yellow on cooling; in R.F. gives a bottle-green color, and if treated on charcoal with metallic tin, assumes a vitriol-green color. With soda on charcoal in R.F. is reduced to a gray magnetic metallic powder. Soluble in concentrated muriatic acid.

Obs.—This ore occurs in rocks of all ages. The specular variety is mostly confined to crystalline or metamorphic rocks, but is also a result of igneous action about some volcanoes, as at Vesuvius. Many of the geological formations contain the argillaceous variety or clay iron-stone, which is mostly a marsh-formation, or a deposit over the bottom of shallow, stagnant water; but this kind of clay iron-stone (that giving a red powder) is less common than the corresponding variety of limonite or siderite. The beds that occur in metamorphic rocks are sometimes of very great thickness, and, like those of magnetite in the same situation, have resulted from the alteration of stratified beds of ore, originally of marsh origin, which were formed at the same time with the enclosing rocks, and underwent metamorphism, or a change to the crystalline condition, at the same time.

Beautiful crystallizations of this species are brought from the island of Elba, which has afforded it from a very remote period, and is described by Ovid as "Insula inexhaustis chalybdum generosa metallis." The surfaces of the crystals often present an irised tarnish and brilliant lustre; the faces *O* and $\frac{1}{2}$ are usually destitute of this tarnish and lustre, and may therefore assist, when present, in determining the situation of other planes when the crystal is quite complex. St. Gothard affords beautiful specimens, composed of crystallized plates grouped in the form of rosettes (*Eisenrose*), and accompanying crystals of feldspar. Near Limoges, France, it occurs in large crystals. Fine crystals are the result of volcanic action at Etna and Vesuvius, and particularly in Fossa Cancharone, on Monte Somma, where it incrusts the ejected lavas; also formed in most recent eruptions about the fumeroles; in that of 1855, in fine crystallizations about the fumaroles some so thin as to be blood-red by transmitted light (Scacchi). Arendal in Norway, Longban in Sweden, Framont in Lorraine, Dauphiny, and Switzerland, also Cleator Moor in Cumberland, afford splendid specimens. Red hematite occurs in reniform masses of a fibrous concentric structure, near Ulverstone in Lancashire, in Saxony, Bohemia, and the Harz. In Westphalia it occurs as pseudomorphs of calcite. In Brazil it is associated with quartz. In Chili there are immense beds.

In *N. America*, widely distributed, and sometimes in beds of vast thickness in rocks of the Azoic age, as in the Marquette region in northern Michigan; and in Missouri, at the Pilot Knob and the Iron Mtn.; the former 650 feet high, consisting mainly of an Azoic quartz rock, and having specular iron in the upper part, the iron ore in heavy beds interlaminated with quartz; the latter 200 feet high, and consisting at surface of massive hematite in loose blocks, many 10 to 20 tons in weight; in Arizona and New Mexico.

Besides these regions of enormous beds, there are numerous others of workable value, either crystallized or argillaceous. Some of these localities, interesting for their specimens, are in northern New York, at Gouverneur, Antwerp, Hermon, Edwards, Fowler, Canton, etc.; Woodstock and Aroostook, Me.; at Hawley, Mass., a micaceous variety; at Piermont, N. H., id.; in New York, in Oneida, Herkimer, Madison, Wayne Cos., a lenticular argillaceous var., constituting one or two beds in the Upper Silurian; the same in Pennsylvania, and as far south as Alabama; and in Canada, and Wisconsin to the west; in North and South Carolina a micaceous variety in schistose rocks, constituting the so-called *specular schist*, or *itabirite*.

This ore affords a considerable portion of the iron manufactured in different countries. The varieties, especially the specular, require a greater degree of heat to smelt than other ores, but the iron obtained is of good quality. Pulverized red hematite is employed in polishing metals, and also as a coloring material. This species is readily distinguished from magnetite by its red streak, and from turgite by its greater hardness and its not decrepitating before the blowpipe.

Named *hematite* from αἱμα, *blood*, it seeming, says Theophrastus, as if formed of concreted blood. This old Greek author speaks afterwards of a second kind of hematites ('Αιματίτης ξανθὴ), which was of a yellowish-white color, probably a yellow ochre, an impure form of limonite, the species long called *brown hematite*.

Alt.—By deoxydation through organic matter forms *magnetite* or protoxyds; and from the latter comes spathic iron by combination with carbonic acid; or by further deoxydation through sulphuretted hydrogen forms *pyrite*. By combination with water forms limonite. Limonite, magnetite, and pyrite constitute occurring pseudomorphs after hematite.

Artif.—Formed in crystals by the action of steam on chlorid of iron, regarded as the probable method of origin of the hematite of lavas; also by the action of perchlorid of iron on lime (Daubrée); by the action of a stream of muriatic acid gas on $\dot{\mathrm{F}}\mathrm{e}$, the application being made very slowly, lest the $\bar{\mathrm{F}}\mathrm{e}$ be all converted to chlorid.

180 A. **MARTITE.** (Martit *Breith.*, Char., 233, 1832). Martite is sesquioxyd of iron under an isometric form, occurring in octahedrons like magnetite (f. 2), and supposed to be pseudomorphous, mostly after magnetite. H.=6–7. G.=4·809–4·832, Brazil, Breith.; 4·65, Puy de Dome; 4·35, Frassem, Devalque; 5·15, Brazil, Ramm.; 5·33, Monroe, N. Y., Hunt. Lustre submetallic. Color iron-black, sometimes with a bronzed tarnish. Streak reddish-brown or purplish brown. Fracture conchoidal. Not magnetic, or only feebly so.

The crystals are sometimes imbedded in the massive sesquioxyd. They are distinguished from magnetite by the red streak, and very feeble, if any, action on the magnetic needle.

Found at the localities mentioned; also in Vermont at Chittenden; in the Marquette iron region south of L. Superior, where crystals are common in the ore, as if all of it, or the greater part, were martite; Bass lake, Canada West; at Monroe, N. Y., in a rock containing quartz, feldspar, and hornblende, and imbedded in each of these minerals; in Moravia, near Schönberg, in granite.

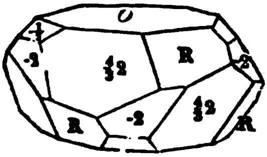
The martite of Monroe contains some $\dot{F}e$, Brush. The octahedral crystals from Chittenden, Vt., according to D. Olmstead, are part true magnetite, with a black powder: part give a slightly reddish streak, with little $\dot{F}e$; and part give a red powder and contain no $\dot{F}e$.

Whether the crystals of martite are original crystals or pseudomorphs is still questioned; but the latter seems to be the most probable view. Pseudomorphism after magnetite would imply that the Marquette ore bed was once all magnetite in composition, $Fe^3\,O^4$, and has been changed to the sesquioxyd, $Fe^2\,O^3$, by an addition of oxygen. Rammelsberg found 1·88—2·30 p. c. of protoxyd of iron in the Brazil crystals. The octahedrons from the fumeroles of Vesuvius afforded Rammelsberg (Min. Ch., 159) $\not{F}e$ 92·91, $\dot{F}e$ 6·17, $\dot{M}g$ 0·82=99·90. The crystals from Frassem, France, contain 0·2 p. c. of sulphur, which suggests that these may be pseudomorphs after pyrite.

181. **MENACCANITE.** Specular Iron pt., Eisensand pt., of last cent. Menachanite (fr. Cornwall) *Wm. McGregor*, J. de Phys., 72, 152, 1791, Crell's Ann., 1791, and Kirwan's Min., 1796 (making it to consist of iron and an oxyd of a probably new metal). Eisenhaltige Titanerze, Menakanit (fr. Cornw.) *Klapr.*, Beitr., ii. 226; (fr. Aschaffenberg) ib., 232, 235, 1797. Titane oxydé ferrifère *H.*, Tr., 1801. Mänaken *Karst.*, Tab., 74, 1808. Titaneisenstein, Titaneisen, *Germ.* Titanic or Titaniferous Iron. Crichtonite (spelt Craitonite) *Bourn.*, Cat., 430, 1813. Axotomes Eisenerz (fr. Gastein) *Mohs*, Grundr., ii. 462, 1824.=Kibdelophan *v. Kob.*, Schweig. J., lxiv. 1832. Ilmenit (fr. L. Ilmen) *A. T. Kupfer*, Kastn. Arch., x. 1, 1827. Mohsite (fr. Dauphiné) *Levy*, Phil. Mag., i. 221, 1827. Hystatisches Eisenerz, Hystatite (fr. Arendal), *Breith.* Ueb., 64, 1830, Char., 236, 1832. Basanomelan (fr. St. Gothard,=Eisenrose) *v. Kob.*, Grundr., 318, 1838. Washingtonite (fr. Conn.) *Shep.*, Am. J. Sci., xliii. 364, 1842. Titanioferrite *Chapm.*, Min., 1843. Paracolumbite (fr. Taunton) *Shep.*, ib., II. xii. 209, 1851.

Rhombohedral; tetartohedral to the hexagonal type. $R \wedge R = 85°\ 40' - 86°\ 10'$, $86°\ 5'$, Rose and Descloizeaux, $85°\ 59'$, Mohs. Observed planes: rhombohedrons, $\frac{2}{5}$, $1(R)$, -5, $-\frac{2}{5}$, -2, $-\frac{1}{2}$; pyramids, $\frac{2}{3}$-2, $\frac{4}{3}$-2, $\frac{10}{3}$-2, which are hemihedral; also *I*, *i*-2, *O*. Angles nearly as in hematite; $O \wedge R = 122°\ 23'$, and $R \wedge \frac{4}{3}\text{-}2 = 154°\ 0'$ when $R \wedge R = 86°$. Often a cleavage parallel with the terminal plane, but properly due to planes of composition. Crystals usually tabular. Twins: composition-face *O*; sometimes producing, when repeated, a form resembling f. 144. Often in thin plates or laminæ; in loose grains as sand.

146



H.=5—6. G.=4·5—5. Lustre submetallic. Color iron-black. Streak submetallic, powder black to brownish-red. Opaque. Fracture conchoidal. Influences slightly the magnetic needle.

Comp., Var.—$(Ti, Fe)^2\,O^3$ (or hematite, with part of the iron replaced by titanium), the proportion of Ti to Fe varying. Rammelsberg writes the formula $\dot{F}e\,\ddot{T}i + n\,\not{F}e$, which is equivalent to $(\frac{1}{2}Fe + \frac{1}{2}Ti)^2\,O^3 + n\,Fe^2\,O^3$, the $Fe^2\,O^3$ being in varying proportions. Sometimes also containing magnesia or manganese, whence the more general formula $(Ti, Fe, Mn, Mg)^2\,O^3$.

The varieties recognized arise mainly from the proportions of iron to titanium. They have been named as follows, commencing with that containing the most titanium. No satisfactory external distinctions have yet been made out:

1. *Kibdelophane.* About 30 p. c. titanium (anal. 1). In crystals, but usually massive, or in thin plates; $R \wedge R = 85°\ 59'$; G.=4·661, fr. Gastein, Mohs; 4·723—4·735, ib., Breith.

2. *Crichtonite.* Composition essentially like that of the preceding (anal. 2 and 23). In acute

rhombohedrons, with basal cleavage; $R \wedge R = 86° \; 62\frac{1}{4}'$; $-5 \wedge -5 = 61° \; 27'$; G.=4·79, from St. Cristophe (original); 4·689, same compound from Ingelsberg, Ramm. (anal. 23); lustre bright.

3. *Ilmenite.* 26—30 p. c. titanium, and near the preceding in composition, but containing more sesquioxyd of iron (anal. 3–6, 27). Crystallized and massive; $R \wedge R = 85° \; 43'$; G.=4·895, fr Ilmen Mts. (original), Breith.; 4·81—4·873, ib., Ramm. For same compound fr. Egersund, 4·744—4·791, Ramm.; fr. Krageröe 4·701.

4. *Menaccanite.* About 25 p. c. of titanium, and with more sesquioxyd of iron than in the preceding (anal. 7–10, 28, 29). Massive, and in grains or as a sand (Eisensand). G.=4·7—4·8, fr. near Menaccan, Cornwall (orig.). Similar compound from Iserwiese, 4·676—4·752, Ramm. (Iserine?)

5. *Hystatite.* 15—20 p. c. titanium, and much $\overline{\text{Fe}}$ (anal. 11–14). $R \wedge R = 86° \; 10'$; G.=5, fr Arendal (orig.). *Washingtonite* belongs here (anal. 13, 14. 30). Occurs in large tabular rather dull crystals; $R \wedge R = 86°$ approximately; G.=4·963, fr. Westerly, R. I., and 5·016, fr. Litchfield Ct. (orig.), Shepard; for latter, 4·986, Ramm.

6. *Uddevallite* D. About 10 p. c. titanium and 70 p. c. of $\overline{\text{Fe}}$ (anal 15). The Aschaffenberg titanic iron is near this. It occurs massive and in plates, and has G.=4·78.

7. *Basanomelan* (*Eisenrose* of the Alps). 6 to 8 p. c. Ti, and 75 to 83 of $\overline{\text{Fe}}$ (anal. 17). G = 4·95—5·21. It is properly a titaniferous hematite.

8. *Krageröe hematite.* Containing less than 8 p. c. of titanium (anal. 35).

9. *Magnesian Menaccanite; Picrotitanite* D. Contains 10 to 15 p. c. of magnesia, anal. 24; formula $(\dot{\text{Fe}}, \dot{\text{Mg}})\ddot{\text{Ti}}$; G.=4·293—4·313. Named from πικρός, *bitter*, in allusion to the magnesia.

The *Mohsite* is of uncertain locality and composition. The occurring rhombohedron affords the angle 73° 45′ (Levy); crystals tabular; in twins; no cleavage observable.

The loose *Iron-sand* of Iserwiese, called *iserine*, is in part, at least, in isometric octahedrons; and the *trappisches Eisenerz*, Breith., is similar. See ISERINE beyond.

Paracolumbite is an iron-black mineral from 1 m. S.W. of Taunton, Mass., having H. about 5. Pisani has proved it to be of this species. He found G.=4·353, H. 4·5.

With the analyses 23 to 35 the ratio of $\dot{\mathrm{F}}\mathrm{e}\ \ddot{\mathrm{Ti}}$ to $\bar{\mathrm{F}}\mathrm{e}$ is given in the last column, from Rammelsberg, who writes the formula for 23, 24, $\dot{\mathrm{F}}\mathrm{e}\ \ddot{\mathrm{Ti}}$; for 25, 6 $\dot{\mathrm{F}}\mathrm{e}\ \ddot{\mathrm{Ti}}+\bar{\mathrm{F}}\mathrm{e}$; for 26, 9 $\dot{\mathrm{F}}\mathrm{e}\ \ddot{\mathrm{Ti}}+\bar{\mathrm{F}}\mathrm{e}$, and so on But calculating the ratio between the metals combined and the oxygen, for these same analyses, we have:

	Metals.	Oxygen.	Ratio.
Anal. 23.	21·77	32·11	1 : 1·48
" 24.	22·71	34·64	1 : 1·52
" 25.	20·67	31·55	1 : 1·50
" 26.	20·09	32·11	1 : 1·60
" 27.	20·58	31·48	1 : 1·53
" 28.	21·17	31·67	1 : 1·50
" 29.	20·62	31·64	1 : 1·54
Anal. 30.	20·52	30·80	1 : 1·50
" 31.	20·29	30·62	1 : 1·51
" 32.	20·14	30·29	1 : 1·50
" 33.	20·07	30·14	1 : 1·50
" 34.	20·23	30·44	1 : 1·50
" 35.	20·13	30·22	1 : 1·50

These ratios are, with two or three exceptions, almost exactly 2 : 3, which shows still better that they correspond with the general formula $R^2\,O^3$. Analyses 1 to 22 afford this same ratio and formula. Rose made the formula m $\ddot{\bar{\mathrm{T}}}\mathrm{i}$ + n $\bar{\mathrm{F}}\mathrm{e}$, assuming that the $\dot{\mathrm{F}}\mathrm{e}$ obtained in the analyses arose from the oxydation of a supposed titanic oxyd ($Ti^2\,O^3$) at the expense of the $\bar{\mathrm{F}}\mathrm{e}$. This view is not sustained, since it has been proved that the $\dot{\mathrm{F}}\mathrm{e}$ exists as such in the ore.

For other analyses: fr. Harzburg in Gabbro, Streng, B. H. Ztg., xxiii. 55; fr. Cape de Verd Isles, Silva, C. R., lxv. 1867; fr. Löbauer Berg, E. Calberla, Ber. Iris Dresd., 1866, 136.

Paracolumbite afforded Pisani $\ddot{\mathrm{Ti}}$ 35·66, $\bar{\mathrm{F}}\mathrm{e}$ 3·48, $\dot{\mathrm{F}}\mathrm{e}$ 39·08, $\dot{\mathrm{M}}$ g1·94, $\dot{\mathrm{C}}\mathrm{a}$ 2·06, $\ddot{\mathrm{Si}}$ and insoluble matters 10·66, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 7·66 (Am. J. Sci., II. xxxvii. 359). It is so mixed with the gangue that it is extremely difficult to obtain it pure. A menaccanite found at Rajamäki, Finland, contains some columbic acid replacing part of the titanic (Pogg., cxxii. 615).

Pyr., etc.—B.B. infusible in O F. although slightly rounded on the edges in R.F. With borax and salt of phosphorus reacts for iron in O.F., and with the latter flux assumes a more or less intense brownish-red color in R.F.; this treated with tin on charcoal changes to a violet-red color when the amount of titanium is not too small. The pulverized mineral, heated with muriatic acid, is slowly dissolved to a yellow solution, which, filtered from the undecomposed mineral and boiled with the addition of tin-foil, assumes a beautiful blue or violet color. Decomposed by fusion with bisulphate of soda or potash.

Obs.—The principal European localities of this species have been enumerated above. One of the most remarkable is at Krageröe, Norway, where it occurs in veins or beds in diorite, which sometimes afford crystals weighing over 16 pounds. Fine crystals, sometimes an inch in diameter, occur in Warwick, Amity, and Monroe, Orange Co., N. Y, imbedded in serpentine and white limestone, and associated with spinel, chondrodite, rutile, etc.; also 4 m. west of Edenville, and near Greenwood furnace with spinel and chondrodite; also at Chester and South Royalston, Mass. Vast deposits or beds of titanic ore occur at Bay St. Paul in Canada, in syenite; one bed, 90 feet thick, continues on in view for 300 feet, and probably far beyond; also in the Seignory of St. Francis, Beauce, mixed with magnetite as a bed 45 feet thick in serpentine; G.=4·56–4·66; also with labradorite at Château Richer. Grains are found in the gold sand of California.

181A. **ISERITE.** (Titaneisenstein pt., Magnetischer Eisen-Sand pt., *Wern.* Iserin (fr. Iser) *Wern.*, Letztes Min., 26, 52, 1817, Hoffm. Min., iv. 258, 1817. Oktaëdrisches Titaneisen-Oxyd *Wern.* Iserin *Breith.*, Char., 51, 1820. Hexaedrisches Eisen-Erz *Mohs*, Min., 436, 1839.) Iserite is supposed to be isometric titanic iron, and, like martite, to be pseudomorphous. Forms like f. 2, 5, 6, 8.

Analyses: 1, Rammelsberg (Min. Ch., 419); 2, v. Hauer (Ber. Ak. Wien, xix. 350); 3, Edwards (Rep. Brit. Assoc., 1855); 4, Vogel and Rischauer (Jahresb., 1856, 840):

	$\ddot{\mathrm{Ti}}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$
1. Iserwiese	57·19	15·67	26·00	1·94=100·60 Ramm.
2. Plattensee, Hung.	30·71	49·93	18·88	3·79=103·31 Hauer.
3. Mersey	13·20	42·08	31·10, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 8·62, $\ddot{\mathrm{Si}}$ 4·02=99·02 Edwards.	
4. Silberberg	18·53	63·00	17·79	——=99·32 V. & R.

The locality of Iserwiese gave the name to this mineral. The titanic iron-sand is partly in octahedral forms, and this portion, if not all, is the *iserine*. Yet it is still doubted whether the otahedrons are regular octahedrons, or whether they are acute rhombohedrons with truncated apices, and therefore true ilmenite. The Iserwiese crystals, as analyzed by Rammelsberg (anal. 1), give for the ratio between the metals and oxygen 2 : 2·33, which is much more oxygen than the formula $R^2 O^3$ requires, and is still further remote from that of magnetite. The ore from Sio-Fok, on the Platensee, as analyzed by v. Hauer (anal. 2), affords the general formula $(Fe, Ti)^2 O^3 + Fe^3 O^4$, equivalent to $Fe O \; Ti O^2 + Fe^3 O^4$ (or $\dot{\text{Fe}} \ddot{\text{Ti}} + \dddot{\text{Fe}}$). G.=4·817. The grains were in part octahedrons, and some with truncated angles.

The sand on the Mersey comes from the shores nearly opposite Liverpool, and is mixed with magnetite. This is indicated in the analysis, which affords the formula $3 \, Fe \, O, Ti \, O^2$ (or $3 \, (Fe, Ti)^2 O^3$) $+ 5 \, \dot{\text{Fe}} \dddot{\text{Fe}}$ (or 5 of magnetite). Minute octahedrons occur at Ballycrogan, Mull of Cantyre. Sand from Müggelsee, near Berlin, having G.=5·075, afforded Rammelsberg a similar composition, but with only 5·20 p. c. $\ddot{\text{Ti}}$, it giving him the formula $Fe \, O \; Ti \, O^2 + 6$ of magnetite. It is not stated that this sand is octahedral. The ore from Silberberg, near Bodenmais, in Bavaria, corresponds nearly to $4\frac{1}{2} \, (Fe, Ti)^2 O^3 + 8 \, Fe^3 O^4$, and therefore comes under the general formula $R^3 O^4$.

Waltershausen has obtained from octahedral crystals of an iron-sand from Etna (Vulk. Gest. 121), having G.=4·43, $\ddot{\text{Ti}}$ 12·38 and $\dddot{\text{Fe}}$ 92·18=104·56. The analysis needs repetition. A. Knop obtained for a titanic iron-sand a composition corresponding to magnetite in atomic ratio, giving the ratio 1 : 1·25 between the metals and oxygen. See under MAGNETITE.

Iserine is reported also from Bohemia, Saxony, Calabria, Puy-de-Dome in France.

182. PEROFSKITE. Perowskit *G. Rose*, Pogg., xlviii. 558, 1839, Reis. Ural, ii. 128.

Isometric, Rose (fr. Ural). (Rhombohedral ?). Observed planes: *O*, *1*, 1, 2, i-$\frac{3}{2}$, i-$\frac{4}{3}$, i-$\frac{5}{4}$, 2-2, 3-3, 2-$\frac{4}{3}$, $\frac{3}{2}$-$\frac{9}{4}$. Habit cubic; f. 1, 5, 16; also 17, except that the planes are i-$\frac{3}{2}$. Rhombohedral, Descl. (fr. Zermatt); with $R \wedge R$ nearly 90°. Perhaps dimorphous. Cleavage: parallel to the cubic, or rhombohedral; faces rather perfect.

H.=5·5. G.=4·017, fr. Achmatovsk; 4·03—4·039, fr. Zermatt, Damour; 4·02, fr. Schelingen, Seneca. Lustre metallic—adamantine; color pale yellow, honey-yellow, orange-yellow, reddish-brown, grayish-black to iron-black; streak colorless, grayish. Transparent to opaque.

Comp.—$(Ca + Ti) O^3 = R^2 O^3$=Titanic acid 59·4, lime 40·6=100. Analyses: 1, Jacobson (Pogg., lxii. 596); 2, Brooks (ib.); 3, 4, F. Seneca (Ann. Ch. Pharm., civ. 371); 5, Damour (Ann. d. M., V. vi. 512):

			$\ddot{\text{Ti}}$	$\dot{\text{Ca}}$	$\dot{\text{Fe}}$	
1.	Achmatovsk, *black*		58·96	39·20	2·06	$\dot{\text{Mg}}$, $\dot{\text{Mn}}$ *tr.*=100·22 Jacobson.
2.	" *brown*		59·00	36·76	4·79	" 0·11—100·07 Brooks.
3.	Schelingen, *black*		58·95	35·69	6·23=100·87 Seneca.	
4.	" "		59·30	35·94	5·99=101·23 Seneca.	
5.	Zermatt, *yellow*	($\frac{1}{2}$)	59·23	39·92	1·14=100·29 Damour.	

Pyr., etc.—In the forceps and on charcoal infusible. With salt of phosphorus in O.F. dissolves easily, giving a greenish bead while hot, which becomes colorless on cooling; in R.F. the bead changes to grayish-green, and on cooling assumes a violet-blue color. Entirely decomposed by boiling sulphuric acid.

Obs.—Occurs in small crystals or druses of crystals, all of dark colors, associated with crystallized chlorite, and magnetic iron in chlorite slate, at Achmatovsk, near Slatoust in the Ural; at Schelingen in the Kaiserstuhl, in white or yellowish granular limestone, with mica, magnetite, and pyrochlore; in the valley of Zermatt, near the Findelen glacier, where crystalline masses occur, in talcose schist, as large as the fist, and the interior, if not the whole, is of a light yellow color (showing that the darker shades are due to alteration), along with garnet, idocrase, sphene, zircon, corundum, rutile, titanic iron, serpentine, etc.; at Wildkreuzjoch, between Pfitsch and Pfunders in the Tyrol, a crystal, probably of this species, having, according to Hessenberg, the planes *O*, *i*, i-$\frac{3}{2}$, 3-3, 2-$\frac{4}{3}$, $\frac{3}{2}$-$\frac{9}{4}$. Also in black cubo-octahedrons at Magnet Cove, Arkansas (Shepard).

Named after v. Perofski of St. Petersburg.

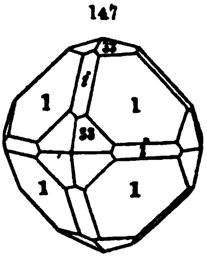
On cryst., see G. Rose, l. c.; Kokscharof, Min. Russl., i. 197; Hessenberg, Min. Not., iv. 20 Descloizeaux. Ann. d. M., V. xiv. 417. If the forms were all isometric, they would still be closely isomorphous with the rhombohedron of hematite.

Artif.—Formed in crystals by making lime to act at a high temperature on silicate of titanium (Ebelmen).

3. COMPOUNDS OF PROTOXYDS AND SESQUIOXYDS.

183. SPINEL.

147



Isometric. Observed planes: 1, *I*, *O*, 2, 3-3. Habit octahedral; f. 2, 7, 8, 20. Faces of octahedron sometimes convex. Cleavage: octahedral. Twins: f. 50; composition-face 1.

H.=8. G.=3·5—4·1; 3·523, Haidinger; 3·575, red spinel. Lustre vitreous; splendent—nearly dull. Color red of various shades, passing into blue, green, yellow, brown and black; occasionally almost white. Streak white. Transparent—nearly opaque. Fracture conchoidal.

Comp., Var.—Consists of alumina and magnesia, $\mathrm{\dot{M}g\,\ddot{\bar{A}}l}$, with more or less of the magnesia ($\mathrm{\dot{M}g}$) usually replaced by protoxyd of iron ($\mathrm{\dot{F}e}$), and sometimes also in part by lime ($\mathrm{\dot{C}a}$), protoxyd of manganese (Mn); and the alumina in part by sesquioxyd of iron ($\mathrm{\ddot{\bar{F}}e}$). There is thence a gradation into kinds containing little or no magnesia, which stand as distinct species, viz.: *Hercynite* and *Gahnite*. $\mathrm{\dot{M}g\,\ddot{\bar{A}}l}$=Alumina 72, magnesia 28=100.

Var. 1. *Ruby*, or *Magnesia Spinel*. Ἄνθραξ pt., Ἄνθρακα περὶ Μίλητον, *Theophr.* Carbunculus pt., Lychnis pt. [rest ruby sapphire], *Plin.*, xxxvii. 25, 29. Spinella, Carbunculus pt., Rubinus pt., Carb ruber parvus, = *Germ.* Spinel, Ballagius (a pallido colore videtur appellasse), = *Germ.* Ballas, Lychnis, = *Germ.* Gelblichter Rubin, *Agric.*, Foss., 293, Interpr., 463, 1546. Rubin orientales octaedrici, seu octo hedris comprehensi, quæ modo triangula sunt, modo trapezia, aliquando hedræ oblongæ angulos solidos occupant, etc., *Cappeler*, Prod. Crystallogr. Lucerne, 1723. Rubinus pt. (Spinell, Ballas, Rubicelle), *Wall.*, Min., 115, 1447. Rubis spinelle octaëdre (Spinelle, Balais), *de Lisle*, Crist., ii. 224, 1783 [by *de L.* first made distinct in species from Ruby Sapphire].—Clear red or reddish; transparent to translucent; sometimes subtranslucent. G.=3·52—3·58. Composition $\mathrm{\dot{M}g\,\ddot{\bar{A}}l}$, with little or no $\mathrm{\dot{F}e}$, and sometimes oxyd of chrome as a source of the red color.

Varieties are denominated as follows: (*a*) *Spinel-Ruby*, deep-red; (*b*) *Balas-Ruby*, rose-red; (*c*) *Rubicelle*, yellow or orange-red; (*d*) *Almandine*, violet.

2. *Ceylonite*, or *Iron-Magnesia Spinel*. Ceylanite (fr. the French spelling of Ceylon) *Delameth.*, J. de Phys., xlii. 23, 1793. Zeylanit *Karst.*, Tab., 28, 72, 1800. Pleonaste *H.*, Tr., 1801. Ceylonit *Ramm.* Candite (fr. Candy, Ceylon) *Bourn.*—Color dark-green, brown to black, mostly opaque or nearly so; G.=3·5—3·6. Composition $\mathrm{(\dot{M}g,\,\dot{F}e)\,\ddot{\bar{A}}l}$ or $\mathrm{(\dot{M}g,\,\dot{F}e)\,(\ddot{\bar{A}}l,\,\ddot{\bar{F}}e)}$.

3. *Magnesia-Lime Spinel?* Color green. From analyses of specimens of green spinel from Franklin, N. J., and Amity, N. Y., by Thomson (Min. i. 214), about which it may be right to have doubts.

4. *Chlorospinel*, or *Magnesia-Iron Spinel*. Chlorospinel (fr. Slatoust) *G. Rose*, Pogg., l. 652, 1840. Gahnit *B. de Marni*, 1833.—Color grass-green, owing to the presence of copper; G.=3·591—3·594. Composition $\mathrm{\dot{M}g\,(\ddot{\bar{A}}l,\,\ddot{\bar{F}}e)}$, the iron being in the state of sesquioxyd.

5. *Picotite* Charpentier, J. d. M., xxxii. 1812, Gilb. Ann., xlvii., 205. *Chrome-ceylonite.*—Contains over 7 p. c. of oxyd of chrome, and has the formula $\mathrm{(\dot{M}g,\,\dot{F}e)\,(\ddot{\bar{A}}l,\,\ddot{\bar{F}}e,\,\ddot{\bar{C}}r)}$. Color black lustre brilliant; G.=4·08. The original was from a rock occurring about L. Lherz, called *Lherzolite* by Delametherie (T. T., ii. 281, 1797), and earlier described by Picot de la Peyrouse (Mem. Ac. Toulouse, iii. 410), after whom *picotite* is named, the constituents of which rock are stated by Descloizeaux (Min., i. 65) to be chrysolite, a brown infusible pyroxene-mineral related to hypersthene, a green fusible pyroxene, and disseminated grains (rarely octahedral crystals) of *picotite*.

Analyses: 1, 2, Abich (Pogg., xxiii. 305); 3, Berzelius (Gehlen's J., vi. 304); 4, 5, Thomson (Min., i. 214); 6, C. Gmelin (Jahresb., iv. 156); 7–10, Abich (l. c.); 11, Abich (Ak. H. Stockh., 1842, 6); 12, Scheerer (Pogg., lxv. 294); 13, Erdmann (Ak. H., Stockh., 1848); 14 Pisani (C. R., lxiii.); 15 16, H. Rose (Pogg., l, 652); 17, Damour (Bull. G. Soc., II. xix. 413) 18, Hilger (Jahrb. Min., 1866, 399):

Pyr., etc.—B.B. alone infusible; red variety changes to brown, and even black and opaque, as the temperature increases, and on cooling becomes first green, and then nearly colorless, and at last resumes the red color. Slowly soluble in borax, more readily in salt of phosphorus, with which it gives a reddish bead while hot, becoming faint chrome-green on cooling. The black varieties give reactions for iron with the fluxes. Soluble with difficulty in concentrated sulphuric acid. Decomposed by fusion with bisulphate of soda or potash.

Obs.—Spinel occurs imbedded in granular limestone, and with calcite in serpentine, gneiss, and allied rocks. It also occupies the cavities of masses ejected from some volcanoes.

In Ceylon, in Siam, and other eastern countries, it occurs of beautiful colors, as rolled pebbles in the channels of rivers. Pleonaste is found at Candy, in Ceylon. At Aker, in Sweden, is found a pale-blue and pearl-gray variety in limestone. Small black splendent crystals occur in the ancient ejected masses of Mount Somma, with mica and idocrase; also in compact gehlenite at Monzoni, in the Fassa valley.

From Amity, N. Y., to Andover, N. J., a distance of about 30 miles, is a region of granular limestone and serpentine, in which localities of spinel abound. At Amity crystals are occasionally 16 in. in diameter; and one collected by Dr. Heron weighs 49 lbs.; it is in three pieces, and contains cavities studded with crystals of corundum; colors, green, black, brown, and less commonly red, along with chondrodite and other minerals. A mile S.W. of Amity, on J. Layton's farm, is a remarkable locality; also on W. Raynor's farm, a mile N.; another half mile N. affording grayish-red octahedrons; and others to the south. Localities are numerous about Warwick, and also at Monroe and Cornwall, though less favorable for exploration than those at Amity (form 1, also 1, i, 3-3, f. 147). Franklin, N. J., affords crystals of various shades of black, blue, green, and red, which are sometimes transparent, and a bluish-green ceylonite variety here, has the lustre of polished steel; Newton, N. J., pearl-gray crystals, along with blue corundum, tourmaline, and rutile; at Byram, red, brown, green, and black colors, along with chondrodite; at Sterling, Sparta, Hamburgh, and Vernon, N. J., are other localities. Light-blue spinels occur sparingly in limestone in Antwerp, Jefferson Co., N. Y., 2¼ m. S. of Oxbow, and rose and reddish-brown in Gouverneur, 2 m. N. and ½ m. W. of Somerville, St. Lawrence Co.; green, blue, and occasionally red varieties occur in granular limestone at Bolton, Boxborough, Chelmsford, and Littleton, Mass. Soft octahedral crystals occur in Warwick, which are pseudomorphs, consisting partly of steatite or serpentine. Good black spinel is found in Burgess, Canada West; blue with clintonite at Daillebout, C. E.

Alt.—Observed altered to steatite, serpentine, völknerite, mica.

Artif.—Formed in crystals by heating a mixture of alumina and magnesia with boracic acid, and also, for red spinel, some oxyd of chrome; for black, oxyd of iron (Ebelmen); by using fluorids of aluminum and magnesium and boracic acid, with heat (Deville & Caron); by action of chlorid of aluminum in vapor on magnesia (Daubrée).

184. HERCYNITE. Hercynit *F. X. Zippe*, Min. Böhm., 1839. Hercinite *bad orthogr.* Iron Spinel.

Isometric. Occurs massive, fine granular.

H.=7·5—8. G.=3·91—3·95. Lustre vitreous, externally dull. Color black. Streak dark grayish-green to leek-green. Opaque.

Comp.—$\dot{F}e\ \bar{\bar{A}}l$=Alumina 58·9, oxyd of iron 41·1=100. Analysis by B. Quadrat (Ann Ch Pharm., lv 357):

$\bar{\bar{A}}l$ 61·17 $\dot{M}g$ 2·92 $\dot{F}e$ 35·67=99·76.

Pyr., etc.—B.B. infusible. The heated powder becomes brick-red, and gives iron reactions With soda fuses only imperfectly to an olive-green mass.

Obs.—From Ronsberg, at the eastern foot of the Böhmerwald Mts.

Named from the Latin of the Bohemian Forest, *Silva Hercynia* (Plin., iv. 25, 28).

185. **GAHNITE.** Zinc-Spinel. Automolite (fr. Fahlun) *Ekeberg*, Afh., i. 84, 1806. Gahnit *v Moll*, Efem., iii. 78, 1807. Spinelle Zincifère *H.*, Tabl., 67, 99, 1809. Dysluite (fr. Sterling N. J.) *Keating*, J. Ac. N. Sci., Philad., ii. 287, 1821; *Shep.*, Min., i. 158, 1832, ii. 176, 1835; *Thomson*, Min., i. 220, 1836. Kreittonite *v. Kob.*, J. pr. Ch., xliv., 99, 1848. Spinellus superius *Breith.*, Handb., 623, 1847.

Isometric. In octahedrons, dodecahedrons, etc., like spinel.

H.=7·5—8. G.=4—4·6. Lustre vitreous, or somewhat greasy. Color dark green, grayish-green, deep leek-green, greenish-black, bluish, black, yellowish, or grayish-brown; streak grayish. Subtranslucent to opaque.

Comp., Var.—$\dot{Z}n\ \bar{\bar{A}}l$, with little or no magnesia. The oxyd of zinc sometimes replaced in small part by protoxyd of manganese or of iron ($\dot{M}n$, $\dot{F}e$), and the alumina in part by sesquioxyd of iron ($\bar{\bar{F}}e$). $\dot{Z}n\ \bar{\bar{A}}l$=Alumina 61·3, oxyd of zinc 38·7=100.

Var. 1. *Automolite*, or *Zinc Gahnite*, $\dot{Z}n\ \bar{\bar{A}}l$, with sometimes a little iron. G.=4·1—4·6. Colors as above given.

2. *Dysluite*, or *Zinc-Manganese-Iron Gahnite*. Composition ($\dot{Z}n$, $\dot{F}e$, $\dot{M}n$) ($\bar{\bar{A}}l$. $\bar{\bar{F}}e$). Color yellowish-brown or grayish-brown. G.=4—4·6. Form the octahedron, or the same with truncated edges.

3. *Kreittonnite*, or *Zinc-Iron Gahnite*. Composition ($\dot{Z}n$, $\dot{F}e$, $\dot{M}g$) ($\bar{\bar{A}}l$, $\bar{\bar{F}}e$). Occurs in crystals, and granular massive. H.=7—8. G.=4·48—4·89. Color velvet to greenish-black; powder grayish-green. Opaque.

Analyses: 1, Ekeberg (Gehlen's N. J., v. 418); 2, 3, Abich (Ak. H. Stockh., 1842, 6); 4, F. A. Genth (Am. J. Sci., II. xxxiii. 196); 5, Thomson (Min., i. 221); 6, v. Kobell (l. c.):

		$\bar{\bar{A}}l$	$\bar{\bar{F}}e$	$\dot{F}e$	$\dot{M}g$	$\dot{M}n$	$\dot{Z}n$	$\dddot{S}i$
1. Fahlun,	*Automolite*	60·00	9·25	——	——	*tr.*	24·25	4·75=98·25 E.

6. Bodenmais,	*Kreitt.*	44·66	16·63	——	8·05	1·80	24·00	Insol. 10=99·64 K.

Pyr., etc.—A coating of oxyd of zinc when treated with a mixture of borax and soda on charcoal. Otherwise like spinel.

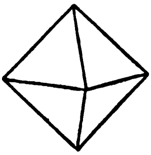
Obs.—*Automolite* is found at Fahlun, Sweden, in talcose schist; at Franklin, N. Jersey, with franklinite and willemite; at the Canton mine, Ga. (of the form 1, *i*); *Dysluite* at Sterling, N. J.; *Kreittonite* at Bodenmais in Bavaria.

Named after the Swedish chemist Gahn. The name *Automolite*, of Ekeberg, is from αὐτόμολος, *a deserter*, alluding to the fact of the zinc occurring in an unexpected place. Von Moll objected to such an idea in nature, and named the species the next year after Gahn, the discoverer. His name is here applied to the whole group of zinc spinels, and automolite retained for the special variety so named.

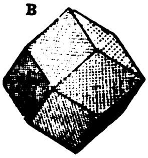
186. **MAGNETITE.** 'Ηράκλεια λίθος (fr. Heraclea, in Lydia) *Gr.* [Λίθος] σίδηρον ἄγουσα, *Theophr.* Not μαγνῆτις λίθος [=Talc] *Theophr.* Μαγνὴς λίθος *Dioscor.*, v. 147. Minera Ferri attractoria, Magnet, *Cronst.*, 184, 1758. Magnetischer Eisenstein (incl. Eisensand) *Wern.* Magneteisenstein, Magneteisenerz, *Germ.* Magnetic Iron Ore; Octahedral Iron Ore. Fer oxydulé *H.* Oxydulated Iron. Magnetite *Haid.*, Handb., 551, 1845.

Isometric. Observed planes, *O*, 1, *I*, *i*-2, 2, 3-3, 10-10, 16-16, 3-$\frac{3}{2}$, 5-$\frac{5}{3}$, $\frac{21}{8}$-3. Figs. 2 and 3, common, also 4, 5, 6, 7, 8, 7+8, 19, 19+2; fig. 149 is a distorted dodecahedron. Cleavage: octahedral, perfect to imperfect

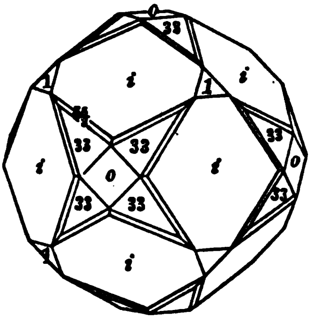
147A



B

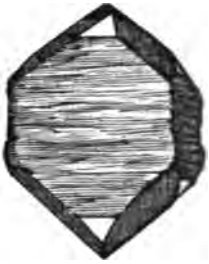


148



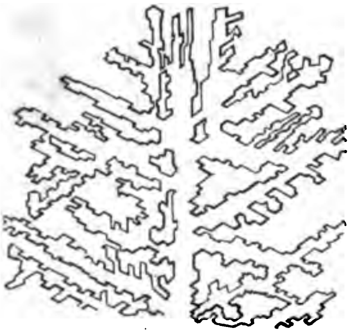
Achmatovsk.

149



Haddam.

150



In mica, Pennsbury.

Dodecahedral faces commonly striated parallel to the longer diagonal (f. 149). Twins like f. 50; also in dendrites, branching at angles of 60° (f. 150), indicating composition parallel to a dodecahedral face. Massive, structure granular—particles of various sizes, sometimes impalpable.

H.=5·5–6·5. G.=4·9–5·2; 5·168—5·180, crystals, Kenngott, and 5·27 after long heating. Lustre metallic—submetallic. Color iron-black; streak black. Opaque; but in very thin dendrites (f. 150) in mica sometimes transparent or nearly so; and varying from almost colorless to pale smoky-brown and black. Fracture subconchoidal, shining. Brittle. Strongly magnetic, sometimes possessing polarity.

Comp., Var.—Ḟe F̶̈e=Oxygen 27·6, iron 72·4=100; or sesquioxyd of iron 68·97, protoxyd 31·03=100. The iron sometimes replaced in small part by magnesia. Also sometimes titaniferous. E. Sochting obtained from the magnetite of Pfitsch valley (Pogg., cxxvii. 172) 30·94 Ḟe; and D. Finkler, from the same, 30·75 Ḟe.

Var. 1. *Ordinary.* (*a*) In crystals. (*b*) Granular, coarse or fine. (*c*) As loose sand. Kokscharof figures the above dodecahedral form modified by planes *O*, 1, 8-3, 5-$\frac{5}{3}$; and another with the same, and also $\frac{21}{8}$-3, both from Achmatovsk, Urals.

2. *Magnesian* (Ḟe, Ṁg) F̶̈e. (Talk-eisenerz *Breith.*, Schw. J., lxviii. 287, 1833.) G.=4·41—4·42, lustre submetallic; weak magnetic; from Sparta, N. J., in crystals, *Breith.* Prof. Andrews found in ore from the Mourne Mts., Ireland (Ch. Gaz., 379, 1852), F̶̈e 71·41, Ḟe 21·59, Mg 6·45. An octahedron from Eisenach gave Rammelsberg (Min. Ch., 158) F̶̈e 69·88, Ḟe 27·88, Mg 1·20, T̈i 0·10.

3. *Titaniferous.* Octahedrons from Meiches, in the Vogelsberg, afforded A. Knop (Ann. Ch Pharm., cxxiii. 348) F̶̈e 21·75, Ḟe 51·29, T̈i 24·95, Mn 1·75, which corresponds to (Ḟe, Mn)+$\frac{1}{2}$ Fe T̈i+$\frac{1}{2}$ F̶̈e=(Ḟe, Mn)+(Fe, Ti)^2 O^3, and hence differing from iserine in coming under the general formula of magnetite instead of that of hematite. Magnetite from Ytterby afforded J. A. Michaelson (J. pr. Ch., xc. 107) F̶̈e 68·54, Ḟe 30·18, T̈i 2·03=100·75.

4. *Ochreous.* (Eisenmulm *Germ.*) Black and earthy. A kind from near Siegen afforded F. A Genth, as a mean of 8 anal. (Ann. Ch. Pharm., lxvi. 277), F̶̈e 66·20, Ḟe 13·87, Mn 17·00, Cu 0·09 sand, etc., 1·75=98·91=(Ḟe Mn) F̶̈e. G.=3·76.

b. From the normal proportion of $\dot{\mathrm{F}}\mathrm{e}$ to $\overline{\mathrm{F}}\mathrm{e}$, 1 : 1, there is occasionally a wide variation, and thus a gradual passage to the sesquioxyd ($\overline{\mathrm{F}}\mathrm{e}$); and this fact may be regarded as evidence that the octahedral $\overline{\mathrm{F}}\mathrm{e}$, martite, is only an altered magnetite. Schwalbe has found (ZS. nat. Ver. Halle, xx. 198) in two magnetites from Landu, in Bengal, India:

	$\overline{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\ddot{\mathrm{S}}\mathrm{i}$	$\overline{\mathrm{A}}\mathrm{l}$	$\overline{\mathrm{F}}\mathrm{e}$: $\dot{\mathrm{F}}\mathrm{e}$
1.	69·27	29·48	0·49	0·05	0·28	0·03=99·60	3 : 1 nearly.
2.	86·90	11·97	0·17	0·38	0·18	0·22=99·82	3½ : 1

No. 1 was polar-magnetic and columnar; 2, granular, and not polar-magnetic. Von Kobell has found in the cylindrical magnetite of Schwarzenstein, in the Zillerthal, the ratio 4 : 3; and the same in an ore from Arendal. G. Winkler found in a specimen from the Pfitsch valley, $\dot{\mathrm{F}}\mathrm{e}$ 19·66, $\overline{\mathrm{F}}\mathrm{e}$ 79·66, giving the ratio 2 : 1; but this is not confirmed by the later analyses given above.

Pyr., etc.—B.B. very difficultly fusible. In O.F. loses its influence on the magnet. With the fluxes reacts like hematite. Soluble in muriatic acid.

Obs.—Magnetite is mostly confined to crystalline rocks, and is most abundant in metamorphic rocks, though found also in grains in eruptive rocks. In the Azoic rocks the beds are of immense extent, and occur under the same conditions as those of hematite (see p. 142). It is an ingredient in most of the massive variety of corundum called emery. The earthy magnetite is found in bogs like bog-iron ore.

The beds of ore at Arendal, and nearly all the celebrated iron mines of Sweden, consist of massive magnetite; Dannemora and the Tāberg in Smaoland are entirely formed of it. Still larger mountains of it exist at Kurunavara and Gelivara, in Lapland. Fahlun in Sweden, and Corsica, afford octahedral crystals (f. 2), imbedded in chlorite slate. Splendid dodecahedral crystals occur at Normark in Wermland. The most powerful native magnets are found in Siberia, and in the Harz; they are also obtained on the island of Elba.

In N. America, it constitutes vast beds (some scores of feet thick) in the Azoic, in the Adirondack region, Warren, Essex, and Clinton Cos., in Northern N. York, while in St. Lawrence Co the iron ore is mainly hematite; also similarly in Canada, in Hull, Grenville, Madoc, etc.; and at Cornwall in Pennsylvania, and at Magnet Cove, Arkansas. It occurs also in *N. York*, in Saratoga, Herkimer, Orange, and Putnam Cos.; at O'Neil mine, Orange Co., in crystals (f. 1, 2, 3, 5, 6). In *Maine*, Raymond, Davis's Hill, in an epidotic rock; at Marshall's island, masses strongly magnetic. In *N. Hampshire*, at Franconia, in epidote and quartz; at Swanzey near Keene, and Unity. In *Vermont*, at Marlboro', Rochester, Bethel, and Bridgewater, in crystals (f 11) in chlorite slate. In *Conn.*, at Haddam, in crystals (f. 4, 8, 149), etc. In *N. Jersey*, at Hamburg, near Franklin furnace. In *Penn.*, at Goshen, Chester Co.; at Webb's mine, Columbia Co.; in dendritic delineations (f. 150) forming hexagonal figures, in mica at Pennsbury and New Providence. In *Maryland*, at Deer Creek. In *California*, in Sierra Co., abundant, massive, and in crystals; in Plumas Co.; Mariposa Co., east of the Mariposa estate, on the trail to the Yosemite; Placer Co., Utt's ranch; Los Angeles Co., at Cañada de las Uvas; El Dorado Co., near the Boston copper mine, in oct., and at the El Dorado Excelsior copper mine. In *Canada*, at Sutton, in crystals; Bromet, etc. In *N. Scotia*, Digby Co, Nichol's Mt., in fine crystals.

No ore of iron is more generally diffused than the magnetic, and none superior for the manufacture of iron. It is easily distinguished by its being attracted readily by the magnet, and also by means of the black color of its streak or powder, which is some shade of red or brown in hematite and limonite. The ore when pulverized may be separated from earthy impurities by means of a magnet, and machines for this purpose are in use.

Named from the loc. *Magnesia*, bordering on Macedonia. But Pliny favors Nicander's derivation from Magnes, who first discovered it, as the fable runs, by finding, on taking his herds to pasture, that the nails of his shoes and the iron ferrule of his staff adhered to the ground.

Alt.—By deoxydation through organic matter changed to protoxyd, which may become a carbonate or siderite. By oxydation becomes sesquioxyd of iron or hematite.

Artif.—Formed in crystals by the action of chlorhydric acid on the sesquioxyd heated, producing a partial deoxydation (Deville); by decomposition of the sesquioxyd with boracic acid (Deville and Caron, Ann. Ch. Phys., IV. v. 108).

185A. *Dimagnetite* of Shepard (Am. J. Sci., II. xiii. 392) appears to be a magnetite pseudomorph. The slender rhombic prisms occur upon a surface which is covered with small cubo-octahedrons dodecahedrons, and cubo-dodecahedrons of magnetite, and some small irregular cavities in the dimagnetite crystals contain similar crystals; moreover no difference of lustre is perceived in a fractured surface of the magnetite and dimagnetite. The species imitated in the pseudomorph is probably Lievrite. The angle of the prism varies between 110° and 115°, according to the author's measurements (Shepard gives the angle 130°). One crystal gave approximately 110° and 70°; another 114° 20′ and 65° 40′; another 112° and 68°, and the obtuse edge was bevelled in this last crystal by planes (*i*-2) inclined to the larger ones at an angle of about 160½°. The faces are even but not very bright. From Monroe, Orange Co., N. Y.

187. MAGNESIOFERRITE. Magnoferrit *Ramm.*, Pogg., cvii. 451, 1859. Magneferrit *Kenng.*, Ueb. J., 1859, 98, 1860.

Isometric. In octahedrons, and octahedrons with truncated edges (f. 8). H.=6—6·5. G.=4·568—4·654. Lustre, color, and streak as in magnetite. Strongly magnetic.

Comp.—$\dot{M}g\ \bar{F}e$=Magnesia 20, oxyd of iron 80=100; but the crystals usually intersected by hematite in innumerable very thin laminæ, parallel to the octahedral faces. Analyses: 1-5, Rammelsberg (Pogg., cvii. 451, Min. Chem., 160):

	$\bar{F}e$	$\dot{M}g$	$\dot{C}u$
1. Vesuvius, erupt. of '55	86·96	12·58	——=99·54
2. " "	85·00	13·69	0·60=99·29
3. " "	85·05	13·95	1·01=100·01
4. " older erupt.	84·20	16·00	——=100·20
5. " "	84·35	15·65	——=100

Regarding a fourth of the sesquioxyd of iron as a mixture, the results give Rammelsberg the above formula. For the purpose of analysis, the magnesioferrite was separated from the mixed hematite by means of a magnet.

Pyr., etc.—B.B. like hematite. Difficultly soluble in muriatic acid.

Obs.—Formed about the fumaroles of Vesuvius, and especially those of the eruption of 1855, as observed by Scacchi, who particularly described the crystals and their associations. The laminæ of hematite intersecting the octahedrons have rhombohedral planes on their edges. Crystals of hematite occur at the same fumaroles.

Rammelsberg first detected the magnesian nature of the crystals, and, in allusion to it, named the species *magnoferrite*. But *magno* has its own different signification in Latin; and the word should be *magnesioferrite*.

Artif.—Formed in crystals by heating together $\bar{F}e$ and $\dot{M}g$, and subjecting to the action of chlorhydric acid vapor (Deville).

188. FRANKLINITE. *Berthier*, Ann. d. M., iv. 489, 1819.

Isometric. Observed planes: 1, *I*, *O*, 2, 2-2. Figs. 2, 7, 8, common. Cleavage: octahedral, indistinct. Also massive, coarse or fine granular to compact.

H.=5·5—6·5. G.=5·069, Thomson; 5·091, Haidinger. Lustre metallic. Color iron-black. Streak dark reddish-brown. Opaque. Fracture conchoidal. Brittle. Acts slightly on the magnet.

Comp.—($\dot{F}e$, $\dot{Z}n$, $\dot{M}n$), ($\bar{F}e$, $\bar{M}n$). Analyses: 1, Berthier (l. c.); 2, Thomson (Min., i. 438); 3, Abich (Pogg., xxiii. 342); 4, 5, G. J. Dickerson (C. T. Jackson's Rep. on N. J. zinc mines); 6, G. J. Brush (Am. J. Sci., II. xxix. 371); 7, Steffens (B. H. Ztg., xix. 463); 8, J. A. Dahlgren (ib.); 9, Rammelsberg (Pogg., cvii. 312); 10, v. Kobell (J. pr. Ch., xcviii. 129):

	$\bar{F}e$	$\bar{M}n$	$\dot{Z}n$
1. New Jersey	66	16	17=99 Berthier.
2. "	66·10	14·96	17·43, $\dddot{S}i$ 0·20, $\dot{\bar{H}}$ 0·56=99·25 Thomson.
3. "	68·88	18·17	10·81, " 0·40, $\ddot{\bar{A}}l$ 0·73=98·99 Abich.

8. "	66·11	11·99	21·77, " 0·13=100 Dahl.
9. "	64·51	13·51	25·30=103·52 Ramm.
10. "	66·20	12·42	21·00, $\ddot{\bar{A}}l$ 0·80=100·42 Kobell.

Von Kobell states that the magnetic character of the mineral shows that the iron is partly protoxyd, and he deduces from his analysis (l. c.), for the most probable composition, $\bar{F}e$ 58·76, $\bar{M}n$

7

75. $\overline{\mathrm{Al}}$ 0·80, $\dot{\mathrm{F}}\mathrm{e}$ 7·06, $\dot{\mathrm{M}}\mathrm{n}$ 3·48, $\dot{\mathrm{Z}}\mathrm{n}$ 21, with mixed $\overline{\mathrm{Mn}}$ 0·79=99·24, corresponding to the formula $\dot{\mathrm{M}}\mathrm{n}$ $\overline{\mathrm{Mn}}$+2 $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Fe}}$ + 5 $\dot{\mathrm{Z}}\mathrm{n}$ $\overline{\mathrm{Fe}}$=Sesquioxyd of iron 58·99, id. of manganese 8·32, protoxyd of iron 7·58, id. of manganese 3·74, oxyd of zinc 21·37=100. Rammelsberg, in his most recent paper (Pogg., cxxx. 146, 1867) adopts essentially the same view. The evolution of chlorine in the treatment of the mineral is attributed by v. Kobell to the presence of a little $\overline{\mathrm{Mn}}$ (0·80 p. c.) as mixture, which Rammelsberg observes may have come from the oxydation of some of the protoxyd of manganese.

Pyr., etc.—B.B. infusible. With borax in O.F. gives a reddish amethystine bead (manganese), and in R.F. this becomes bottle-green (iron). With soda gives a bluish-green manganate, and on charcoal a faint coating of oxyd of zinc, which is much more marked when a mixture of borax and soda is used. Soluble in muriatic acid, with evolution of a small amount of chlorine.

Obs.—Occurs in cubic crystals near Eibach in Nassau; in amorphous masses at Altenberg, near Aix la Chapelle.

Abundant at Hamburg, N. J., near the Franklin furnace (whence the name of the species), with red oxyd of zinc and garnet, in granular limestone; also at Stirling Hill, in the same region, where it is associated with willemite, in a large vein, in which cavities occasionally contain crystals from one to four inches in diameter.

Artif.—Formed in crystals by action of perchlorid of iron and chlorid of zinc on lime, with heat (Daubrée).

189. CHROMITE.

Fer chromaté aluminé (fr. Var) *Vauq.*, Bull. Soc. Philom. 1800, 55, 57. Eisenchrom (fr. Ural) *Meder*, Crell's Ann., 1798, i. 500; *Karst.*, Tab., 56, 79, 1800, 74, 1808. Fer chromaté *H.*, Tr., iv. 1801. Chromate of Iron, Chromic Iron, Chromiron. Chromsaures Eisen, Chromeisenstein, *Germ.* Eisenchrome *Beud.*, 1832. Sidérochrome *Huot*, i. 287, 1841. Chromoferrite *Chapm.*, Min., 1843. Chromit *Haid.*, Handb., 550, 1845.

Isometric. In octahedrons (f. 2). Commonly massive; structure fine granular, or compact.

H.=5·5. G.=4·321, crystals, Thomson; 4·498, a variety from Styria; 4·568, Texas, Pa. Lustre submetallic. Streak brown. Color between iron-black and brownish-black. Opaque. Fracture uneven. Brittle. Sometimes magnetic.

Comp.—$\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Cr}}$, or ($\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{g}$, $\dot{\mathrm{C}}\mathrm{r}$) ($\overline{\mathrm{Al}}$, $\overline{\mathrm{Fe}}$, $\overline{\mathrm{Cr}}$). $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Cr}}$=Oxyd of iron 32, oxyd of chromium 68 =100. **Analyses**: 1, 2, Seybert (Am. * With some titanic acid ?

In Moberg's analysis the chromium is supposed to be partly protoxyd, giving the formula ($\dot{\mathrm{F}}\mathrm{e}$ $\dot{\mathrm{M}}\mathrm{g}$, $\dot{\mathrm{C}}\mathrm{r}$) ($\overline{\mathrm{Cr}}$, $\overline{\mathrm{Al}}$). Garrett's analysis of the Texas ore corresponds to $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Cr}}$ 93·16 + $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Fe}}$ 0·59 + $\dot{\mathrm{N}}\mathrm{i}$ $\overline{\mathrm{Fe}}$ 1·15. In grains that were magnetic, Garrett found $\overline{\mathrm{Cr}}$ 41·55, $\overline{\mathrm{Fe}}$ 62·02, $\ddot{\mathrm{S}}\mathrm{i}$ 1·25, corresponding to $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Cr}}$ 61·07 + $\dot{\mathrm{F}}\mathrm{e}$ $\overline{\mathrm{Fe}}$ 38·64 + $\ddot{\mathrm{S}}\mathrm{i}$ 1·25=100·96 (loc. cit).

Pyr., etc.—B.B. in O.F. infusible; in R.F. slightly rounded on the edges, and becomes magnetic. With borax and salt of phosphorus gives beads which, while hot, show only a reaction for iron, but on cooling become chrome-green; the green color is heightened by fusionon charcoal with metallic tin.

Not acted upon by acids, but decomposed by fusion with bisulphate of potash or soda.

Obs.—Occurs in serpentine, forming veins, or in imbedded masses. It assists in giving the variegated color to verde-antique marble.

Occurs in the Gulsen mountains, near Kraubat in Syria; in crystals in the islands of Unst and Fetlar, in Shetland; in the province of Drontheim in Norway; in the Department du Var in France; in Silesia and Bohemia; abundant in Asia Minor (Am. J. Sci., II. vii. 285); in the Eastern and Western Urals; in New Caledonia, affording ore for commerce.

At Baltimore, Md., in the Bare Hills, in large quantities in veins or masses in serpentine; also in Montgomery Co., 6 m. north of the Potomac; at Cooptown, Harford Co., and in the north part of Cecil Co., Md. In Pennsylvania, in W. Goshen (crystals), Nottingham, Mineral Hill, and elsewhere; Chester Co., near Unionville, abundant; at Wood's Mine, near Texas, Lancaster Co., very abundant. Massive and in crystals at Hoboken, N. J., in serpentine and dolomite; in the south-western part of the town of New Fane, and in Jay, Troy, and Westfield, Vt.; Chester and Blanford, Mass.; on I. à Vache, near San Domingo; at Bolton and Ham, Canada East. In California, in Monterey Co.; also Santa Clara Co., near the N. Almaden mine.

This ore affords the oxyd of chrome, used in painting, etc. The ore employed in England is obtained mostly from Baltimore, Drontheim, and the Shetland Isles; it amounts to about 2,000 tons annually.

IRITE *Herm.*, J. pr. Ch., xxiii. 276, 1841, was described by Hermann as occurring in the Urals in black shining octahedrons, with G.=6·506, and as consisting of Iridium 56·04, osmium 9·53, iron 9·72, chromium 9·40, traces of manganese, with a loss of 15·25, which he reckoned as oxygen. But Claus has shown that the mineral is only a mixture of iridosmine, chromite, etc., and sustains this by a mechanical examination of the substance obtained by Hermann's method of separation (J. pr. Ch., lxxx. 285).

190. URANINITE. Schwarz Beck-Erz (fr. Joach.) *Brückm.*, Magn. Dei, 204, 1727. Beck-Blände=Pseudogalena picea pt. [rest (? all) pitch-like Zinc-blende] *Wall.*, 249, 1747. Uranin *Haid.*, Handb., 549, 1845.

Schweruranerz (fr. Przibram) *Breith.*, Handb., 903, 1847. Coracite (fr. L. Sup.) *Le Conte*, Am. J. Sci., II. iii. 117, 173, 1847. Kristallisirtes Uranpecherz (fr. Norway) *Th. Scheerer*, Pogg., lxxii. 570, 1847=Uranoniobit *Herm.*, J. pr. Ch., lxxvi. 326, 1859.

Isometric. Observed forms: f. 2, 7, 8. Usually massive and botryoidal; also in grains: structure sometimes columnar, or curved lamellar.

H.=5·5. G.=6·4–8. Lustre submetallic, to greasy or pitch-like, and dull. Color grayish, greenish, brownish, velvet-black. Streak brownish-black, grayish, olive-green, a little shining. Opaque. Fracture conchoidal, uneven.

Comp., Var.—$\dot{U}\,\dddot{\bar{U}}$, Ramm.=Protoxyd of uranium 32·1, sesquioxyd 67·9=100; but analyses vary much in their results through mixtures with other substances.

Var. 1. *Crystallized.* Color pure black; G.=6·71. Occurs in Norway. It is Hermann's *Uranoniobite.*

2. *Ordinary* massive. G.=6·4–7·0. Breithaupt found in 11 trials of the ore from Johanngeorgenstadt and Schneeberg (the heaviest from the latter place) G.=6·44–6·934, with one at 5·625. A specimen from the former locality gave F. Marian 7·08–7·23; and one from Joachimsthal gave Hermann (anal. 5) 6·97. The Przibram ore (*Schweruranerz*) gave Breithaupt, in 4 trials, G.= 68–8·025.

Coracite. Coracite is probably pitchblende mixed with some gummite (the hydrous ore). It lack in color, and affords a grayish powder; G.=4·378, Le Conte. In Whitney's analysis he obtained 15·92 p. c. of carbonate of lime, which accounts for the low specific gravity. was separated by Genth, as far as possible, before making his analysis (No. 9). Genth the oxygen ratio for the $\dot{U}$ and $\dddot{\bar{U}}$ nearly 1 to 4.

dinger's name is retained for the species, with the addition of the terminal syllable ite 's has precedence; but it is badly made, its derivation requiring the form *Uranatomite*, moreover, until crystals are known and found to be without cleavage, or until crystals are to be an impossibility, it cannot be asserted that the species is *uncleavable*.

Analyses: 1, Klaproth (Beitr., ii. 197); 2, Rammelsberg (Pogg., lix. 35, and Min. Ch., 175); 3, (Ramm. Min. Ch., 175); 4, Ebelmen (Ann. Ch. Phys., 1843, 498); 5, Hermann (J. pr. Ch., 326); 6, Pfaff (Schw. J., xxxv. 326); 7, v. Hauer (Jahrb. G. Reichs., 1853, 197); 8, Whit (Am. J. Sci., II. vii. 434); 9, Genth (ib., xxiii. 421); 10, Scheerer (Pogg., lxxii. 561):

10. Norway, Uranoni.	76·6				$\dot{Pb}$, $\ddot{C}b$, $\dddot{Si}$ 15·6, $\dot{Mn}$ 1·0, $\dot{H}$ 4·1, insol. and loss 2·7 Scheerer.

Scheerer, in anal. 5, obtained $\dddot{\bar{U}}$ 52·37, and $\dot{U}$ 28·84; and Genth, in anal. 9, $\dddot{\bar{U}}$ 46·21, and $\dot{U}$ 16·47.

Pyr., etc.—B.B. infusible, or only slightly rounded on the edges, sometimes coloring the outer green (copper). With borax and salt of phosphorus gives a yellow bead in O.F., becoming in R.F. (uranium). With soda on charcoal gives a coating of oxyd of lead, and frequently odor of arsenic. Many specimens give reactions for sulphur and arsenic in the open tube. in nitric acid. Not attractable by the magnet.

Obs.—Uraninite accompanies various ores of silver and lead at Johanngeorgenstadt, Marien- and Schneeberg in Saxony, at Joachimsthal and Przibram in Bohemia, and Retzbanya in It is associated with torbernite at Tincroft and Tolcarn mines near Redruth in Corn- also near Adrianople, Turkey; at the Middletown feldspar quarry, in octahedrons with trun- edges, according to Shepard.

is from about 90 m. above Sault St. Marie, on the north side of L. Superior.

valuable in porcelain painting, affording an orange color in the enamelling fire, and a black in that in which the porcelain is baked. A laboratory has been opened at Joachimsthal, the ore is converted into uranate of soda for use.

Alt.—The hydrous ore called gummite occurs as a result of the alteration of this species; also ochre.

CHRYSOBERYL. [Not Chrysoberyl (=var. Beryl) of *the Ancients*.] Krisoberil *Wern.*, J., 373, 387, 1789; 84, 1790. Chrysoberyll *Karsten*, *Lenz*, etc. Cymophane *H.*, J. de 1798. 155A

Haddam.

Plane *i-ī* vertically striated; an sometimes also *i-ĭ*, and other vertica planes. Cleavage: 1-*ĭ* quite distinct *i-ĭ* imperfect; *i-ī* more so. Twins composition-face 3-*ĭ*, as in f. 153, 155 made up of 6 parts by the crossing o 3 crystals, united along the dotte line, as shown by the striæ, the form either stellate, or simply hexagona pyramids with truncated summits also (2) conjointly, 3-*ĭ* and *i-ĭ*, a in f. 154, 155, each made by the crossing of 3 pairs of twins, each sector pair twinned by 3-*ĭ*, and united to the next pair by *i-ĭ*.

H. = 8·5. G. = 3·5—3·84. Lustre vitreous. Color asparagus-green grass-green, emerald-green, greenish-white, and yellowish-green; sometime raspberry or columbine-red by transmitted light. Streak uncolored. Trans parent—translucent. Sometimes a bluish opalescence internally. Fractur conchoidal, uneven.

Var. 1. *Ordinary.*—Color pale green, being colored by iron. G.=3·597, Haddam; 3·73 Brazil; 3·689, Ural, Rose; 3·835, Orenburg, Kokscharof.

2. *Alexandrite.*—Color emerald-green, but columbine-red by transmitted light. G.=3·644, mea of results, Kokscharof. Supposed to be colored by chrome. Crystals often very large, and i wins, like fig. 153, either six-sided or six-rayed.

Comp.—$\dot{\text{B}}\text{e}^3\ddot{\text{A}}\text{l}$=Alumina 80·2, glucina 19·8=100. Analyses: 1, 2, 3, Avdejef (Pogg., lv 118); 4, 5, Damour (Ann. Ch. Phys., III. vii. 173):

	$\ddot{\text{A}}\text{l}$	$\dot{\text{B}}\text{e}$	$\dot{\text{F}}\text{e}$
1. Brazil	78·10	17·94	4·47=100·51 Avdejef; G.=3·7337.
2 "	78·71	18·06	3·47=100·24 "
3. Ural	78·92	18·02	3·12, $\ddot{\text{C}}\text{r}$ 0·36, $\dot{\text{C}}\text{u}$ and $\dot{\text{P}}\text{b}$ 0·29=100·71 Avdejef.
4. Haddam, Ct.	76·02	18·41	——, $\ddot{\text{F}}\text{e}$ 4·51, quartz 0·49=99·43 Damour.
5. "	75·43	17·93	——, " 4·06, " 0·96=98·38 "

Pyr., etc.—B.B. alone unaltered; with soda, the surface is merely rendered dull. With bora or salt of phosphorus fuses with great difficulty. With cobalt solution, the powdered miner gives a bluish color. G. hardly changed by heating; before 3·84, after 3·833. No action with acids.

Obs.—In Brazil and also Ceylon, in rolled pebbles, in the alluvial deposits of rivers; at Marchendorf in Moravia; in the Ural, 85 versts from Katherinenburg, in mica slate with beryl and phenacite, the variety *Alexandrite*, of emerald-green color, columbine-red by transmitted light; in the Orenberg district, S. Ural, yellow; in the Mourne Mts., Ireland; at Haddam, Ct., in granite traversing gneiss, with tourmaline, garnet, beryl, automolite, and columbite; in the same rock at Greenfield near Saratoga, N. Y., with tourmaline, garnet, and apatite; Orange Summit, N. H., in granite at the deep cut of the northern railroad; Norway, Me., in granite with garnet (Verrill).

When transparent, and of sufficient size, chrysoberyl is cut with facets, and forms a beautiful yellowish-green gem. If opalescent, it is usually cut *en cabochon*.

Chrysoberyl is from χρυσός, *golden*, βήρυλλος, *beryl*. *Cymophane*, from κῦμα, *wave*, and φαίνω, *appear*, alludes to a peculiar opalescence the crystal sometimes exhibits. *Alexandrite* is after the Czar of Russia, Alexander I.

On Cryst., see B. & M.; Kokscharof, Min. Russl., iv.; Hessenb., Min. Not., iv. Fig. 152 is natural size, from a crystal belonging to A. E. Verrill. Chrysoberyl has very distinct cleavage parallel to 1-ī, which appears to show that 1-ī is the true vertical prism as made in the last edition of this work, although 3-ī is the twinning-plane. But, for the sake of the simpler notation, the position given the crystals by other authors is here adopted.

Artif.—Formed in crystals by exposing to a high heat a mixture of 6 of alumina, 1·62 glucina, and 5·0 boric acid (Ebelmen); by putting a mixture of fluorid of glucinum and fluorid of aluminum, in the proportions of their equivalents, in a carbon crucible, and at the centre of the fluorids a small carbon crucible with a little fused boric acid, and heating for some hours (Deville and Caron), the process yielding fine crystals easily.

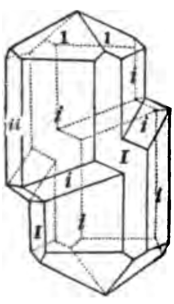
$O \wedge 3\text{-}\frac{3}{2} = 112° 25'$
$1 \wedge 1$, pyr., $= 121\ 40$
$1 \wedge 1$, bas., $= 87\ 7$

$I \wedge 1 = 133° 34'$
$1\text{-}i \wedge 1\text{-}i$, pyr., $= 133\ 31$
$I \wedge i\text{-}\frac{3}{2} = 168\ 42$

Cleavage: *I* and *i-i* hardly distinct. Twins: f. 158, composition-face 1-*i*; producing often complex forms through the many modifying planes; sometimes repeated parallel to all the eight planes 1-*i*; also f. 159, a metagenic twin. Often in reniform shapes, structure fibrous divergent: also massive, granular or impalpable.

159



H.=6–7. G.=6·4–7·1. Lustre adamantine, and crystals usually splendent. Color brown or black; sometimes red, gray, white, or yellow. Streak white, grayish, brownish. Nearly transparent—opaque. Fracture subconchoidal, uneven. Brittle.

Var.—1. *Ordinary*, Tin-stone. In crystals and massive. G. of ordinary cryst. 6·96; of colorless, from Tipuani R., Bolivia, 6·832, Forbes; of honey-yellow, from Oruro, 6·704, id.; of very pure crystals from Carabuco, 6·4, id.; of black cryst. fr. Tipuani, 7·021, id.

2. *Wood Tin* (Holz-Zinn *Germ.*). In botryoidal and reniform shapes, concentric in structure, and radiated fibrous internally, although very compact, with the color brownish, of mixed shades, looking somewhat like dry wood in its colors. *Toad's-eye* tin is the same, on a smaller scale. G. of one variety 6·514. Excellent figs. in Rashleigh's Brit. Min., 1797.

Stream tin is nothing but the ore in the state of sand, as it occurs along the beds of streams or in the gravel of the adjoining region. It has been derived from tin veins or rocks, through the wear and decomposition of the rocks and transportation by water.

Comp.—$\ddot{\mathrm{Sn}}$=Tin 78·67, oxygen 21·33=100. Analyses: 1, Berzelius (Afh., iv. 164); 2, Mallet (J. G. Soc. Dubl., iv. 272); 3, Bergemann (Jahrb. Min., 1857, 395); 4, 5, D. Forbes (Phil. Mag., IV. xxx. 140):

5. " " *black*	91·80	—	2·69	—	5·51		=100 Forbes. G.=7·021.

Crystals from Carabuco, Bolivia, afforded Kroeber (Phil. Mag., IV. xxx. 141) 76·805 p. c. of tin (equivalent to 97·8 p. c. of oxyd), with iron 2·18, silver 0·015, tungstic acid 0·02, lead 0·25, and 1·74 of water. (The analysis is stated to have afforded 19·584 of oxygen, which is not enough for the tin alone found.) The Tenebra ore contains from 2 to 5 p. c. of columbic and tantalic acids. Vauquelin obtained 9 p. c. of sesquioxyd of iron from wood tin.

Pyr., etc.—B.B. alone unaltered. On charcoal with soda reduced to metallic tin, and gives a white coating. With the fluxes sometimes gives reactions for iron and manganese, and more rarely for tantalic acid. Only slightly acted upon by acids.

Obs.—Tin ore is met with in veins traversing granite, gneiss, mica schist, chlorite or clay schist, and porphyry.

Occurs in remarkable crystals in Cornwall, associated with fluor, apatite, topaz, blende, wolfram, etc., and also the *wood-tin* and *stream-tin;* in Devonshire, near Tavistock and elsewhere: County of Wicklow, Ireland; in pseudomorphs after feldspar at Wheal Coates, near St. Agnes, Cornwall; singular compound crystals in Bohemia and Saxony, the twin forms from Zinnwald and Schlackenwald often weighing several pounds; at Limoges in splendid crystals; also in Gallicia; Greenland, with cryolite at Evigtok, Sweden, at Finbo; Finland, at Pitkaranta.

In the E. Indies, on Malacca, Banca, Blitong near Borneo; in the Ovens district, and in some gullies of the Strathbogie ranges in Victoria, Australia.

In Bolivia, S. A., in the gold region along the Tipuani R.; at Oruro tin mines; and at Carabuco, Bolivia; in Mexico, at Xeres and Durango.

In the United States, in *Maine*, sparingly at Paris and Hebron; in *Mass.*, at Chesterfield and Goshen, a few crystals, with albite and tourmaline; in *N. Hamp.*, at Lyme, and somewhat more abundantly on the estate of Mr. Eastman, in the town of Jackson; in *Virginia*, sparingly in some gold mines, imbedded in a talco-micaceous slate; in *California*, in San Bernardino Co., in Temescal region; in *Idaho*, on Jordan creek, near Boonville.

Stannite Breith. (Handb. 772, 1847), an amorphous, pale yellowish-white substance, from Cornwall, with H.=6·5, G.=3·545, has been regarded as a pseudomorph after feldspar, con taining much oxyd of tin as a mixture with the other ingredients. Bischof obtained (Chem. G., ii. 2026) S̈i 51·57, S̈n 38·91, A̶̶l 4·53, F̶e 3·55, Ċa 0·16, ign. 0·43=99·15.

On cryst., Hessenberg, Min. Not., vi.; A. E. Nordenskiöld and Gadolin, Pogg., ci. 637. Nordenskiöld makes the angle 1 ∧ 1=121° 42′, whence *a*=0·6720. According to Mr. Gadolin, Finland crystals afford also the planes $\frac{2}{3}$, 7, $\frac{19}{7}$-$\frac{19}{16}$, $\frac{17}{6}$-$\frac{17}{12}$, $\frac{7}{2}$-$\frac{7}{4}$, $\frac{4}{3}$-$\frac{8}{3}$, $\frac{7}{6}$-$\frac{7}{2}$, 1-3, *i*-$\frac{7}{6}$, *i*-$\frac{11}{8}$, *i*-$\frac{9}{7}$, *i*-$\frac{5}{4}$, *i*-$\frac{6}{5}$, *i*-$\frac{7}{6}$, *i*-$\frac{4}{3}$, *i*-$\frac{11}{10}$, *i*-$\frac{4}{3}$, *i*-$\frac{33}{32}$; but there is doubt as to some at least of these planes, as these unusual ratios were determined from measured angles alone and not through zones.

Artif.—Formed in crystals by the action of a stream of muriatic acid gas on Sn O^2 (Deville); by action of steam on chlorid or fluorid of tin (Daubrée).

192A. AINALITE *A. E. Nordenskiöld* (Finl. Min., 162, 1855, 26, 1863). A cassiterite containing nearly 9 p. c. of tantalic acid. Isomorphous with cassiterite, and presenting the planes 1, 1-*i*. H.=6–6·5; G.=6·6—6·8. Lustre vitreous to adamantine; color black to grayish-black; streak light-brown; opaque. Analysis by Nordenskiöld:

S̈n 88·95 T̈a 8·78 F̶e 2·04 Ċu 0·78=100·55

From Fennikoja in Somero, Finland, with tantalite and beryl in albite.

Cleavage: *I* and *i-i*, distinct; 1, in traces. Vertical planes usually striated. Crystals often acicular. Twins: 1, composition-face 1-*i*, either (1) having a geniculation at the centre of origin of the crystal (nearly like f. 50, or f. 158 under cassiterite); or (2) having commenced as a simple crystal, and afterward become geniculated, as in f. 161. (A) Usually the successive geniculations take place in a common plane, that is by those faces 1-*i* that lie in the direction of the same diagonal; and (*a*) either the parts at the geniculations, at the opposite extremities, resume alternately a like direction, as in f. 159, under cassiterite, p. 157; or the direction changes successively (f. 161), the extremities finally bending into one another, and producing at times when thus completed an inequilateral hexagonal prism (f. 162); but (B) occasionally the twinned commencement (as I, II, f. 163) is next geniculated at either end parallel to the *transverse* plane 1-*i*, and a zig-zag form is produced, and this in successive alternations, thence resulting, if the twinning begins nearly at, or at, the commencement of the crystal, in the scalenohedral form in f. 164, which consists of 8 united sectors. [Fig. 163 is ideal (from G. Rose), being introduced to illustrate the form in f. 164.] 2. Composition-face 3-*i*, making a wedge-shaped crystal consisting of two individuals. 3. Composition-faces 1-*i* and 3-*i* in the same crystal (fr. Magnet Cove, Hessenberg). Occasionally compact, massive.

H.=6–6·5. G.=4·18–4·25. Lustre metallic-adamantine. Color reddish-brown, passing into red; sometimes yellowish, bluish, violet, black; rarely grass-green. Streak pale brown. Subtransparent—opaque. Fracture subconchoidal, uneven. Brittle.

Comp., Var.—Titanic acid, $\ddot{\mathrm{T}}\mathrm{i}$=Oxygen 39, titanium 61=100. Sometimes a little iron is present.

Var. 1.—*Ordinary.* Brownish-red and other shades, not black. G.=4·18–4·22. Transparent quartz is sometimes penetrated thickly with acicular or capillary crystals, and this variety is the *Sagenite* (fr. σαγηνη, a net), also named *Crispite.* Dark smoky quartz penetrated with the acicular rutile is apparently the *Veneris crinis* of Pliny (xxxvii. 69).

2. *Ferriferous.* (*a*) *Nigrine.* Color black, whence the name. Contains 2 to 3 p. c. of oxyd of iron. But as ordinary rutile has 1 to 2 p. c., the distinction is very small. G.=4 249, fr. Ohlapian; 4·242 fr. Freiberg. (*b*) *Ilmenorutile.* A black variety from the Ilmen Mts, occurring in octahedrons, containing over 10 p. c. of oxyd of iron, and having G.=5·074–5·133.

3. *Chromiferous* (Titane oxydé chromifère *H.*). A grass-green variety, containing oxyd of chrome, which gives the color.

Analyses: 1, Damour (Ann. Ch. Phys., III. x. 417); 2, H. Rose (Gilb. Ann., lxiii. 67, Pogg., iii 166); 3, Kersten (J. pr. Ch., xxxvii. 170); 4, 5, Demoly (Jahresb., 1849, 728):

4.	Loc. unknown	96·41	1·63, $\ddot{\bar{\mathrm{M}}}\mathrm{n}$ 0·13, $\ddot{\mathrm{S}}\mathrm{i}$ 1·83=100 Demoly.	
5.	" "	96·45	1·62, " 0·14, " 0·79=100 Demoly.	

[a] In part at least *magnetite*, which may be separated by a magnet.

The *Ilmenorutile* consists approximately, according to Hermann (l. c.), of $\ddot{\mathrm{T}}\mathrm{i}$ 89·3, $\bar{\mathrm{F}}\mathrm{e}$ 10·7.

Pyr., etc.—B.B. infusible. With salt of phosphorus gives a colorless bead, which in R.F. assumes a violet color on cooling. Most varieties contain iron, and give a brownish-yellow or red bead in R.F., the violet only appearing after treatment of the bead with metallic tin on charcoal. Insoluble in acids; made soluble by fusion with an alkali or alkaline carbonate. The solution containing an excess of acid, with the addition of tin-foil, gives a beautiful violet-color when concentrated.

Obs.—Rutile occurs in granite, gneiss, mica slate, and syenitic rocks, and sometimes in granular limestone and dolomite. It is generally found in imbedded crystals, often in masses of quartz or feldspar, and frequently in acicular crystals penetrating quartz. It has also been met with in hematite and ilmenite. It is common in grains or fragments in many auriferous sands. Occurs in Arendal and Krageröe in Norway; at Horrsjöberg, Finland, with lazulite and kyanite; Saualpe Carinthia · in the Urals; in the Tyrol; at St. Gothard; at Yrieix, in France; Krummhenners dorf near Freiberg; in Castile, in geniculated crystals, often large; at Ohlapian in Transylvania, *nigrine* in pebbles; in large crystals in Perthshire, Scotland; at Crianlarick, at Craig Calleach near Killin and on Benygloe; in Donegal Co., Ireland. A variety from Karingsbricka in Sweden contains according to Ekeberg (Ak. H., Stockh., 1803, 46), 3 p. c. of chrome, and is the *titane oxydé chromifère* of Haüy; *grass-green* needles, supposed to be chromiferous, have been found in the Swiss Alps. The *Ilmenorutile* is from the phenacite and topaz mine of the Ilmen Mts., in the Urals. Rough octahedrons, reticulated within, from Brazil, are supposed to be pseudomorphs after anatase.

In *Maine*, at Warren, along with tremolite and chalcopyrite. In *N. Hamp.*, sparingly at Lyme, with tourmaline; near Hanover, acicular crystals in quartz, only in loose masses. In *Vermont*, at Waterbury, Bristol, Dummerston, and Putney; also in loose boulders in middle and northern Vermont, acicular, some specimens of great beauty in transparent quartz. In *Mass.*, at Barre, in gneiss, crystals occasionally an inch and a half in diameter; at Windsor, in feldspar veins intersecting chlorite slate; at Shelburne, in fine crystals in mica slate; at Leyden, with scapolite; at Conway, with gray epidote. In *Conn.*, at Lane's mine, Monroe, and in the adjoining town of Huntington. In *N. York*, in Orange Co., 1 m. E. of Edenville, with pargasite in limestone boulders, 2 m. E. of Warwick, in granite with zircon; 1 m. E. of Amity, in quartz with brown tourmaline, and 2 m. W., with spinel and corundum, and also 2 m. S.W., with red spinel and chondrodite; near Warwick, in slender prisms penetrating quartz; in N. York Co., at Kingsbridge, in veins of quartz, feldspar, and mica traversing granular limestone; in the limestone of Essex Co. In *Penn.*, in fine long crystals, at Sudsbury, Chester Co., and the adjoining district in Lancaster Co.; at Parksburg, Concord, West Bradford, and Newlin, Chester Co.; at the Poor House quarry, Chester Co., in delicate crystals, sometimes iridescent, on dolomite. In *N. Jersey*, at Newton, with spinel. In *N. Car.*, at Crowder's Mountain. In *Georgia*, in Habersham Co.; in Lincoln Co., at Graves' Mountain, with lazulite in large and splendent crystals, some 3½ by 2½ in. In *Arkansas*, at Magnet Cove.

In *Canada*, small crystals, with specular iron at Sutton, C. E.; in the ilmenite of Bay St. Paul, C. E., orange translucent grains, pure T̈i, and probably rutile or brookite.

The oxyd of titanium is employed for a yellow color in painting porcelain, and also for giving the requisite tint to artificial teeth.

Recent art. on cryst., Kokscharof Min. Russl., i. ii. iii. iv.; Pogg., xci. 154 (whence angles given); G. Rose, Pogg., cxv. 643; Hessenberg, Min. Not., I. II. V. Figs. 162–164 by G. Rose.

Artif.—Formed in crystals by heating together to redness titanic acid and protoxyd of tin, and then heating the mass with silica to a cherry red heat (Deville); by the action of steam on fluorid or chlorid of titanium (Daubrée, Hautefeuille). Hautefeuille observes that in this process crystals of *rutile* are formed when the heat used is red heat; of *brookite*, when it is between that required for volatilizing cadmium and zinc; and of *anatase*, when the heat is a little below that required for the volat. of cadmium.

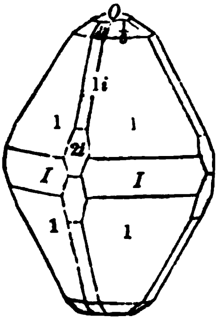
Has been observed in crystals as a furnace product by Scheerer.

194. **OCTAHEDRITE.** Schorl bleu indigo (fr. Oisans) *Bourn.*, de Lisle's Crist., ii. 406, 1783; Schorl octaèdre rectangulaire *id.*, J. de Phys., xxx. 386, 1787. Octaédrite *Sauss.*, Alpes, § 1901, 1796. Oktaëdrit *Wern.*, 1803, Ludwig's Wern., ii. 218, 1804. Oisanite *Delameth.*, T. T., ii. 269, 1797; *H.*, J. d. M., v. 273, 1799. Anatase *H.*, Tr., iii. 1801. Dauphinit.

Tetragonal. $O \wedge 1\text{-}i=119° 22'$; $a=1{\cdot}77771$. Commonly octahedral or tabular. Observed planes: O; prisms, I, $i\text{-}i$; octahedrons, 1, $\frac{1}{3}$, $\frac{8}{7}$, $\frac{1}{2}$, $\frac{1}{5}$, $\frac{1}{7}$, $3\text{-}i$, $2\text{-}i$, $1\text{-}i$, $\frac{1}{5}\text{-}i$, $\frac{1}{7}\text{-}i$; zirconoid, $\frac{5}{19}\text{-}5$.

$O \wedge \frac{1}{5}=153° 19'$ — $1 \wedge 1$, bas., $=136° 36'$
$O \wedge \frac{1}{7}=160\ 15$ — $2\text{-}i \wedge 2\text{-}i$ " $=148\ 28$
$O \wedge 1=111\ 42$ — $1\text{-}i \wedge 1\text{-}i$ " $=121\ 16$
$O \wedge 2\text{-}i=105\ 46$ — $O \wedge I=90.$
$1 \wedge 1$, pyr., $=97\ 51$ — $I \wedge 1=158\ 18$

165



Cleavage: 1 and O, perfect.

H.=5·5–6. G.=3·82–3·95; sometimes 4·11—4·16 after heating. Lustre metallic-adamantine. Color various shades of brown, passing into indigo-blue, and black; greenish-yellow by transmitted light. Streak uncolored. Fracture subconchoidal. Brittle.

Comp.—Like rutile and brookite, pure titanic acid.

Rose found in crystals from Brazil 1·25 per cent. sesquioxyd of iron (Pogg., lxi. 516); and Damour obtained in an analysis (Ann. Ch. Phys., III. x. 417), $\ddot{\mathrm{Ti}}$ 98·36, $\bar{\mathrm{Fe}}$ 1·11, $\ddot{\mathrm{Sn}}$ 0·20=99·67

Pyr., etc.—Same as for rutile.

Obs.—Most abundant at Bourg d'Oisans, in Dauphiny, with feldspar, axinite, and ilmenite Found in mica slate in the Grisons; in Bavaria; near Hof in the Fichtelgebirge; Norway; the Urals; in chlorite in Devonshire, near Tavistock; with brookite at Tremadoc, in North Wales; in Cornwall, near Liskeard and at Tintagel Cliffs; in Brazil in quartz, and in detached crystals so splendent as to be sometimes mistaken for diamonds.

In the U. States, at the Dexter lime rock, Smithfield, R. I., in dolomite.

De Saussure's name *octahedrite* has the priority, and is particularly appropriate, the crystals being usually octahedrons. Haüy's *anatase* is No. 3 in order of time, and was brought forward after he had once adopted for a while Delametherie's name *oisanite*; it is from *ἀνάτασις*, *erection*, and was intended to signify, as Haüy says, that the common octahedron was longer than that of other tetragonal species; but *length* is not in the meaning of the Greek word.

Artif.—Formed in crystals by the action of steam on chlorid or fluorid of titanium (Daubrée); by the action of a stream of muriatic acid gas on Ti O^2 (Deville); by fusing titanic acid with salt of phosphorus B.B. in R.F., and then exposing the bead to the point of the blue flame, when minute transparent crystals of octahedrite separate (G. Rose).

195. HAUSMANNITE. Schwarz Braunsteinerz pt. *Wern.*, Bergm. J., 386, 1789. Schwarz Manganerz pt. *Karst.*, Tab. 72, 100, 1808. Black Manganese. Blättricher Schwarz-Braunstein *Hausm.*, Handb., 293, 1813. Manganése oxydé hydraté *H.*, Tr., 1822. Pyramidal Manganese Ore *Haid.*, Mohs, Min., ii 416, 1824. Hausmannite *Haid.*, Trans. R. Soc. Ed., 1827. Glanzbraunstein *Hausm.*, Handb., 405, 1847.

Tetragonal. $O\wedge1\text{-}i=130^\circ\ 25'$; $a=1·1743$. Observed planes: 1, $\frac{1}{2}$, 1-i. Forms octahedral.

$O\wedge1=121^\circ\ 3'$ $\qquad$ $\frac{1}{2}\wedge\frac{1}{2}$, pyr., $=139^\circ\ 57'$
$1\wedge1$, pyr., $=105\ 25$ $\qquad$ $1\text{-}i\wedge1\text{-}i$, " $=114\ 52$
$O\wedge\frac{1}{2}=151\ 2$ $\qquad$ $1\wedge1\text{-}i=142\ 42$

Cleavage: basal, nearly perfect. Twins, parallel to 1-i; the same kind of composition sometimes between four individuals, nearly like 93, p. 65. Also granular massive, particles strongly coherent.

H.=5–5·5. G.=4·722. Lustre submetallic. Color brownish-black. Streak chestnut-brown. Opaque. Fracture uneven.

Comp.—$\dot{\mathrm{M}}\mathrm{n}^2\ddot{\mathrm{Mn}}$=Manganese 72·1, oxygen 27·9=$\bar{\mathrm{Mn}}$ 69, $\dot{\mathrm{Mn}}$ 31=100. Formula usually written $\dot{\mathrm{Mn}}\,\bar{\mathrm{Mn}}$. Analyses: 1, Turner (Trans. Roy. Soc. Edinb., xi.); 2, Rammelsberg (Pogg., xiv. 222); 3, id. (ib., cxxiv. 523); 4, L. J. Igelström (Œfv. Ak. Stockh., 1865, 606):

	$\dot{\mathrm{Mn}}$	$\bar{\mathrm{Mn}}$	O	$\dot{\mathrm{Ba}}$	$\dddot{\mathrm{Si}}$	$\dot{\mathrm{H}}$
1. Ilefeld	98·902		0·215	0·111	0·337	0·435=100 Turner.
2. Ilmenau	92·487	——	7·004	1·150	——	——=99·641 Ramm.
3. Filipstad	92·12	——	6·95	0·13	——	0·34, $\dot{\mathrm{Ca}}$ 0·14, $\dot{\mathrm{Mg}}$ 0·41=100·09 Ramm.
4. Jakobsberg	28·78	71·27	——	——	——	——=100 Igelström.

Rammelsberg, in later examinations of the Ilmenau mineral (Pogg., cxxiv. 522), found $\dddot{\mathrm{Si}}$ 0·1 0·91, 0·60, and $\dot{\mathrm{Ba}}$ 0·15, 0·60, 0·14, with ign. 0·5, and O 7·10.

Pyr., etc.—B.B. like manganite. Dissolves in heated muriatic acid, affording chlorine.

Obs.—Occurs with porphyry, along with other manganese ores, in fine crystals, near Ilmenau in Thuringia; Ilefeld in the Harz; Filipstad in Wermland. Reported also from Framont in Alsace. Observed at Lebanon, Penn.

Dauber found for crystals from Ilmenau $1\wedge1=105^\circ\ 30'$, and $\frac{1}{2}\wedge\frac{1}{2}=140^\circ\ 31'$ (Pogg., xciv. 406).

The formula $\dot{\mathrm{M}}\mathrm{n}^2\ddot{\mathrm{Mn}}$, which makes the two members each to contain *two of oxygen*, accords with the approximate isomorphism of the species with octahedrite and rutile, the angle $O\wedge1$ in it differing hardly 2° from $O\wedge1\text{-}i$ in octahedrite, and about $2\frac{1}{2}$° from $O\wedge1$ in rutile.

Artif.—Formed in crystals by subjecting $\bar{\mathrm{Mn}}$ and $\dot{\mathrm{Mg}}$ to heated muriatic acid gas (Deville).

196. BRAUNITE. Braunite, Brachytypous Manganese-Ore, *Haid.*, Ed. J. Sci., iv. 48, 1826 Hartbraunstein *Hausm*, Handb., 222, 1847. Marceline *Beud.*, ii. 188, 1832. Heteroklin *Breith.* Pogg., xlix. 204, 1840 (in art. by Evreinoff), Handb., 801, 1847.

Tetragonal. *O* ∧ 1-*i*=135° 26′; *a*=0·98525. Observed planes: *O*, 1, 2, 2-2:

O ∧ 1=125° 40′
O ∧ 2=109 45
1 ∧ 1, pyr.,=109 53
1 ∧ 1, bas.,=108 40
2 ∧ 2, pyr.,=96° 33′
2 ∧ 2, basal,=140 30
2-2 ∧ 2-2, pyr. axial,=128 17
2-2 ∧ 2-2, pyr. diag.,=144 4

1 ∧ 1=109° 46′ and 108° 53′, Descloizeaux. Twins: forms consisting of three crystals, Kenngott. Also massive.

H.=6—6·5. G.=4·75—4·82; 4·752, fr. Elgersburg, Ramm.; 4·818, ib., Haid.; 4·77, fr. St. Marcel, Damour. Lustre submetallic. Streak and color dark brownish-black. Fracture uneven. Brittle.

Comp.—$2\,\mathrm{Mn}^3\,\dot{\mathrm{Mn}}+\dot{\mathrm{Mn}}\,\ddot{\mathrm{Si}}$ (see p. 138). Turner obtained no silica, and made the mineral simply $\overline{\mathrm{Mn}}$. Analyses: 1, Turner (Edinb. Trans., xi.); 2–4, Rammelsberg (Pogg., cxxiv. 515):

				$\dot{\mathrm{Mn}}$	O	$\dot{\mathrm{Ba}}$	$\ddot{\mathrm{Si}}$	$\dot{\mathrm{H}}$
1. Elgersburg				86·95	9·85	2·25	*tr.*	0·95=100 Turner.
2. "	cryst.	([illegible])		*undet.*		0·24	7·98	—— Ramm.
3. "	massive	([illegible])		"		0·54	8·32	—— Ramm.
4. "				[80·94]	8·08	0·44	8·63	1·00, $\dot{\mathrm{C}}\mathrm{a}$ 0·91=100 Ramm.

The *marceline* (or heterocline) from St. Marcel in Piedmont, shown chemically by Damour, and crystallographically by Descloizeaux, to be impure braunite, was found by Damour (Ann. d. M., IV. i. 400) to consist of

$\overline{\mathrm{Mn}}$ 66·68, $\overline{\mathrm{Fe}}$ 10·04, $\dot{\mathrm{Mn}}$ 8·79, $\dot{\mathrm{Fe}}$ 1·30, $\dot{\mathrm{C}}\mathrm{a}$ 1·14, $\dot{\mathrm{Mg}}$ 0·26, $\ddot{\mathrm{Si}}$ 10·24=98·45

Analyses of impure ore from Elba, by Bechi, in Am. J. Sci., II. xiv. 62; from Engadin, in serpentine, by Bukeisen, in Ber. Ak. Wien, xxiv. 287.

Pyr., etc.—B.B. infusible. With borax and salt of phosphorus gives an amethystine bead in O.F., becoming colorless in R.F. With soda gives a bluish-green bead. Treated with muriatic acid evolves chlorine. Marceline gelatinizes with acids.

Obs.—Occurs both crystallized and massive, in veins traversing porphyry, at Oehrenstock, near Ilmenau; at Elgersburg in Thuringia; at Botnedalen, Upper Tellemark, in Norway; near Ilefeld in the Harz; at St. Marcel in Piedmont· at Elba (Bechi, Am. J. Sci., II. xiv. 62); at Vizianagram in India.

Named after Mr. Braun of Gotha.

To exhibit the true relations between the forms of braunite and cassiterite or rutile, the plane 1-*i* above should be 1, *O* ∧ 1 in cassiterite being 136° 26′. Homologically this plane in all these related species is 1-*i*, the plane corresponding to that truncating an edge of a cube which inclines to *O* 135°.

197. MINIUM. Mennige *Germ.* Plomb oxidé rouge *H.*

Pulverulent, occasionally exhibiting, under the microscope, crystalline scales.

H.=2—3 G.=4·6. Lustre faint greasy, or dull. Color vivid red, mixed with yellow; streak orange-yellow. Opaque.

Comp.—$\mathrm{Pb^3\,O^4}=\ddot{\mathrm{Pb}}+2\,\dot{\mathrm{Pb}}$=Oxygen 9·34, lead 90·66=100.
Pyr.—In the reduction flame of the blowpipe globules of lead are obtained.
Obs.—Usually associated with galenite, and also with calamine, and sometimes constituting pseudomorphs after galenite and cerussite.

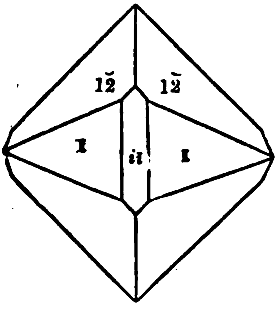
Occurs at Bleiaif in the Eifel; in Badenweiler in Baden; Brillon in Westphalia; island of Anglesey; Grassington Moor and Weardale in Yorkshire; Leadhills in Scotland; Schlangenberg in Siberia.

Found at Austin's mine, Wythe Co., Va., along with cerussite.

198. BROOKITE. Jurinite *Soret*, 1822. Brookite *Levy*, Ann. Phil., II. ix. 140, 1825. Arkansite *Shep.*, Am. J. Sci., II. ii. 250, 1846. ? Eumanite *Shep.*, ib., xii. 211, 1851.

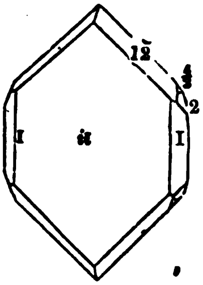
Orthorhombic. $I \wedge I = 99° \ 50'$ ($-100° \ 50'$): $O \wedge 1\text{-}\bar{i} = 131° \ 42'$; $a:b:c = 1{\cdot}1620:1:1:1{\cdot}1883$. Observed planes: O; vertical, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\bar{\tfrac{3}{2}}$, $i\text{-}\bar{2}$, $i\text{-}4$, $i\text{-}\tfrac{11}{2}$, $i\text{-}\tfrac{11}{4}$, $i\text{-}\breve{2}$; domes, $\tfrac{1}{4}\text{-}\bar{i}$, $\tfrac{1}{2}\text{-}\bar{i}$, $2\text{-}\breve{i}$; octahedral, $\tfrac{1}{2}$, 1, 2, $\tfrac{1}{2}\text{-}\bar{\tfrac{3}{2}}$, $\tfrac{3}{2}\text{-}\bar{\tfrac{3}{2}}$, $1\text{-}\breve{2}$, $2\text{-}\breve{2}$, $\tfrac{7}{3}\text{-}\tfrac{7}{3}$, $5\text{-}\breve{\ }$, $5\text{-}\tfrac{10}{3}$, $2\text{-}\breve{\tfrac{8}{7}}$, $2\text{-}\breve{\tfrac{4}{3}}$.

166

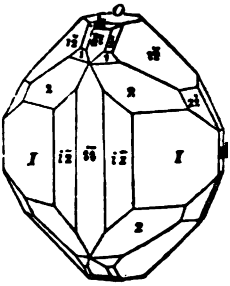


Arkansas.

167

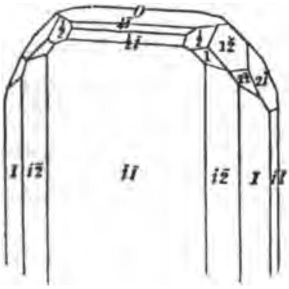


168



Miask, Ural.

169



Ellenville, N. Y.

$O \wedge \tfrac{1}{2}\text{-}\bar{i} = 150° \ 42'$
$O \wedge \tfrac{1}{2}\text{-}\bar{\tfrac{3}{2}} = 147 \ \ 14$
$O \wedge 1 \ \ = 124 \ \ 17$
$O \wedge \tfrac{1}{2} \ \ = 143 \ \ 45$
$O \wedge 2\text{-}\breve{\tfrac{4}{3}} = 111 \ \ 34$
$O \wedge 1\text{-}\breve{2} = 132 \ \ 19$
$O \wedge 5\text{-}\breve{5} = 101 \ \ 38$
$O \wedge 2\text{-}\breve{i} = 117 \ \ 54$

$I \wedge i\text{-}\bar{i} = 139° \ 55'$
$i\text{-}\bar{i} \wedge i\text{-}\bar{2} = 157 \ \ 11$
$i\text{-}\bar{2} \wedge i\text{-}\bar{2}$, mac., $= 134 \ \ 22$

$1 \wedge 1$ " $= 115 \ \ 43$
$1\text{-}\breve{2} \wedge 1\text{-}\breve{2}$ " $= 101 \ \ 3$
$1\text{-}\breve{2} \wedge 1\text{-}\breve{2}$, brach., $= 135 \ \ 37$
$2\text{-}\breve{i} \wedge 2\text{-}\breve{i}$, top, $= 55 \ \ 48$

Cleavage: I, indistinct; O, still more so.

H.=5·5—6. G.=4·12—4·23, brookite; 4·21—4·23, trp. Ural cryst.; 4·03—4·085, arkansite, Whitney and Damour, 3·86—3·95, Rammelsberg, 3·81, a variety from the Ural, Hermann. Hair-brown, yellowish, or reddish, with metallic adamantine lustre, and translucent (brookite); also iron-black, opaque, and submetallic (arkansite). Streak uncolored—grayish, yellowish. Brittle.

Comp.—Pure titanic acid, $\ddot{\text{T}}\text{i}$, like rutile. Analyses: 1, Hermann (J. pr. Ch., xlvi. 404); 2 Romanovsky (B. H. Ztg., 1853, No. 26); 3, Damour (Ann. d. M., IV. xv. 447):

	$\ddot{\text{T}}\text{i}$	Fe	$\ddot{\text{A}}\text{l}$	ign.
1. Urals	94·09	4·50	*tr.*	1·40=100·00 Hermann.
2. "	94·31	3·28	——	1·31=98·90 Romanovsky
3. Arkansas	99·36	1·36	0·73	——=101·45 Damour.

Rammelsberg obtained 94·23 p. c. of titanic acid from the arkansite, and a corresponding low specific gravity, while Whitney and Damour found little impurity and a higher specific gravity.

Pyr., etc.—Same as for rutile.

Obs.—Brookite occurs at Bourg d'Oisans in Dauphiny: at St. Gothard, with albite and quartz in the Urals, district of Slatoust, near Miask; near Makirch in the Vosges, in pseudomorphs after sphene; rarely at Val del Bove, Etna, with rutile; at Fronolen near Tremadoc, Wales; in thick black crystals (*arkansite*, f. 166) at Magnet Cove, Ozark Mts., Arkansas, along with elæolite, black garnet, and schorlamite; in small crystals from the gold washings of North Carolina; at the lead mine of Ellenville, Ulster Co., N. Y., on quartz (f. 169), with chalcopyrite and galenite; at Paris, Maine.

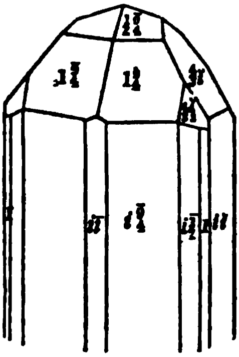
$I \wedge I$ in arkansite$=$100°—100° 30′, $1\text{-}\breve{2} \wedge 1\text{-}\breve{2}=$101° 30′, and 135° 15′ to 135° 50′. In brookite from the Urals, $I \wedge I=$99° 50′, Kokscharof (Min. Russl.).

Named after the English crystallographer and mineralogist, H. J. Brooke.

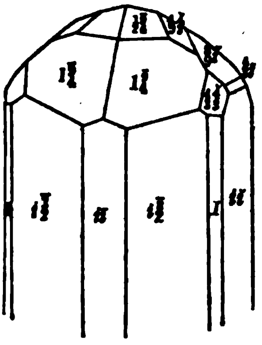
Artif.—Formed in crystals by the action of steam on chlorid or fluorid of titanium (Daubrée).

198A. EUMANITE. Eumanite occurs in minute crystals at the Chesterfield albite vein with rubellite and pyrochlore. Its chemical identity with brookite has not been ascertained. The annexed are figures, by the author, of two of the crystals.

170



170A



Some of the observed angles are $I \wedge I=$100° to 101°, $\frac{1}{3}\text{-}\breve{i} \wedge \frac{1}{3}\text{-}\breve{i}=$77° 49′, $i\text{-}\frac{3}{4} \wedge i\text{-}\frac{3}{4}=$140°—140° 15′, $i\text{-}\breve{i} \wedge \frac{1}{3}\text{-}\frac{3}{4}=$128° 20′—128° 30′, $i\text{-}\breve{i} \wedge i\text{-}\frac{3}{4}=$108°. Am. J. Sci., II. xii. 211, 397, xiii. 117.

199. **PYROLUSITE.** Lapis manganensis pt. *Cæsalp.*, Metall., 1596. Brunsten = Magnesia pt. *Wall.*, 268, 1747; Manganese pt. *Fr. Trl.* Wall., i. 483, 1753. 171

Orthorhombic. $I \wedge I=$93° 40′, $O \wedge 1\text{-}\bar{i}=$142° 11′; $a:b:c=0{\cdot}776:1:1{\cdot}066$. Observed planes as in the figure. $O \wedge \frac{1}{2}\text{-}\breve{i}=$160°, $I \wedge i\text{-}\bar{i}=$136° 50′ $I \wedge i\text{-}\breve{i}=$133° 10′, $\frac{1}{2}\text{-}\breve{i} \wedge \frac{1}{2}\text{-}\breve{i}$, top,$=$140°. Cleavage I and $i\text{-}\breve{i}$. Also columnar, often divergent; also granular massive, and frequently in reniform coats. Often soils.

H.=2—2·5. G.=4·82, Turner; Lustre metallic. Color iron-black, dark steel-gray, sometimes bluish. Streak black or bluish-black, sometimes submetallic. Opaque. Rather brittle.

Var.—1. *Ordinary.* In (*a*) crystals and (*b*) massive. H.=2—2·5; G.=4·819, Turner; 4 84, fr. Andalusia. Angles as above given.

2. *Polianite.* H. above 5. G.=4·838—4·880, fr. Platten, Breith. Color light steel-gray. Angles, $I \wedge I=92° 52'$, $O \wedge 1\text{-}\bar{i}=147° 43'$. It is a very pure pyrolusite. Pisani states that "polianite" from Cornwall has G.=4·826.

3. *Varvacite* is impure pyrolusite. See under MANGANITE.

Comp.—$\ddot{\rm Mn}$=Manganese 63·3, oxygen 36·7=100. Analyses: 1, Arfvedson (Schw. J., xlii. 210); 2, 3, Turner (Edinb. Trans., 1828); 4, Scheffler (Arch. Pharm., xxxv. 260); 5, Plattner (Pogg., lxi. 192):

	$\dot{\rm Mn}\overline{\rm Mn}$	O	$\dot{\rm Ba}$	$\ddot{\rm Si}$	$\dot{\rm H}$
1. Undenaes?	83·56	14·58	——	——	1·86=100 Arfvedson.
2. Elgersberg	84·05	11·78	0·53	0·51	1·12=100 Turner.
3. Ilefeld	85·62	11·60	0·66	0·55	1·57=100 Turner.
4. Ilmenau	87·0	11·6	1·2	0·8	5·8, $\overline{\rm Fe}$ 1·3, $\dot{\rm Ca}$ 0·3, $\overline{\rm Al}$ 0·3 S
5. Platten, *Pol.*	87·27	12·11	——	0·13	0·32, $\overline{\rm Fe}$ $\overline{\rm Al}$ 0·17=100 Platt

In another specimen Scheffler found 9·7 per cent. of baryta. Specimens from near Battenberg Hesse, afforded Schwarzenberg and Engelhardt 96·45 to 100 per cent. of pure superoxyd of manganese (Ann. Ch. Pharm., lxi. 262). V. Sevoz and J. Breuilhs find in crystallized ore from Huelva in Andalusia, $\ddot{\rm Mn}$ 97·9, $\overline{\rm Fe}$ 0·5, $\dot{\rm H}$ 1·1=99·5; and in a massive, $\ddot{\rm Mn}$ 96·9, $\overline{\rm Fe}$ 1·0, $\dot{\rm H}$ 0·5, $\ddot{\rm Si}$ 1·0=99·4 (Bull. Soc. de l'Ind. Min., vi. 29, Rev. Geol. par Delesse, 1860, 57).

Pyr., etc.—B.B. alone infusible; on charcoal loses oxygen. A manganese reaction with borax. Affords chlorine with muriatic acid.

Obs.—This ore is extensively worked at Elgersberg near Ilmenau, and other places in Thuringia; at Vorderehrensdorf near Mährish-Trübau, in Moravia, which place annually affords many hundred tons of the ore; at Platten in Bohemia, and elsewhere. Fine crystals occur near Johanngeorgenstadt, and at Hirschberg in Westphalia, and crystalline plates at Matzka, Transylvania; also found sparingly in Cornwall; in Timor; in Australia.

Occurs in the United States with psilomelane, abundantly in Vermont, at Brandon, Irasburg, Bennington, Monkton, Chittenden, etc., both crystallized (f. 171) and massive; at Conway, Mass., in a vein of quartz; at Plainfield and West Stockbridge, Mass.; at Winchester, N. H.; at Salisbury and Kent, Conn., forming velvet-like coatings on limonite. In California, on Red island, bay of San Francisco. In New Brunswick, 7 m. fr. Bathurst, in fine cryst.; in Shepody Mtn. and elsewhere; near Upham in King's Co. In Nova Scotia, at Teny cape, cryst. and massive; also at Walton, abundant; near Kentville; Pictou; Amherst; Musquodobit.

Pyrolusite and manganite are the most important of the ores of manganese. Pyrolusite parts with its oxygen at a red heat, and is extensively employed for discharging the brown and green tints of glass. It hence received its name from πῦρ, *fire*, and λύω, *to wash*; and for the same reason it is whimsically entitled by the French *le savon de verriers*. It is easily distinguished from psilomelane by its inferior hardness, and usually by being crystalline.

200. CREDNERITE. Kupferhaltiges Manganerz *Credner*, Jahrb. Min., 5, 1847. Mangankupferoxyd *Hausm.*, Handb., 1582, 1847. Mangankupfererz, Crednerit, *Ramm.*, Pogg., lxxii. 559.

Monoclinic. Foliated crystalline. Cleavage: basal very perfect; less distinct in two other directions obliquely inclined to one another.

H.=4·5. G.=4·9—5·1. Lustre metallic. Color iron-black to steel-gray. Streak black, brownish.

Comp.—$\dot{\rm Cu}^3\,\overline{\rm Mn}^2$=Oxyd of copper 42·9, oxyd of manganese 57·1=100; but often mixed with oxyd of manganese. Analyses: 1, Credner (Pogg., lxxiv. 555); 2–4, Rammelsberg (l. c., and Min. Ch., 178):

	$\dot{\rm Mn}$	$\overline{\rm Mn}$	$\dot{\rm Cu}$	$\dot{\rm Ba}$	$\dot{\rm Ca}$	$\dot{\rm H}$	O

2. "	52·55	——	40·65	1·48	——	——	5·78=100·46 Ramm.
3. "	56·29	——	32·35	3·08	0·76	——	8·58=99·06 Ramm.
4. "	64·24	——	23·73	2·01	——	——	8·83=98·81 Ramm.

Pyr., etc.—B.B. fusible only on thin edges. With borax in O.F. gives a dark violet color (manganese); with salt of phosphorus a green glass, which on cooling is blue, and in R.F. becomes red (copper). Soluble in muriatic acid with evolution of chlorine.

Obs.—From Friederichsrode, with volborthite, malachite, and manganese ores. Rammelsberg observes that this ore is undoubtedly the source of the cupreous manganese, a secondary product

201 PLATTNERITE. Schwerbleierz *Breith.*, J. pr. Ch., x. 508, 1837. Plattnerit *Haid.*, Handb. 504, 1845. Braunbleioxyd *Hausm.*, Handb., 202, 1847.

In hexagonal prisms with replaced basal edges, planes O, I, 1, but pseudomorphous after pyromorphite (Greg); cleavage indistinct. G.=9·39—9·45. Lustre metallic adamantine. Color iron black. Streak brown. Opaque.

COMP.—According to Plattner (J. pr. Ch., x. 508), $Pb\,O^2$=Lead 86·6, oxygen 13·4=100. Probably from Leadhills, Scotland. A doubtful species. The specific gravity given is as high as that of the protoxyd of lead.

201A. VANADIO OCHRE.—(Vanadic acid *Teschemacher*, Am. J. Sci., II. xi. 233, 1851.) A yellow pulverulent substance, encrusting masses of native copper, along with quartz, at the Cliff mine, Lake Superior, according to J. E. Teschemacher (l. c.). The color before the blowpipe changed to black; also the powder, boiled in nitric acid, afforded an apple-green solution, from which, on partial evaporation, after standing some weeks, red crystalline globules formed on the surface, which, as they enlarged, fell to the bottom; by means of these crystalline masses the vanadates of silver and lead were made. As no metal was found in the first solution, the yellow mineral was inferred to be probably vanadic acid ($V\,O^3$).

In other determinations for No. 5, $\dot{H}$=5·02 and 5·09 p. c.; for specimens from Lehigh valley, Pa., 5·34 Rœpper.

Pyr., etc.—Heated in a closed tube, flies to pieces in a remarkable manner, and in this distinct from hematite and limonite; yields water. Otherwise like hematite.

Obs.—A very common ore of iron, often taken for limonite, with which it is frequently associated, and which it resembles, except in its superior hardness, streak, and decrepitation. It also looks very much like fibrous hematite. Hermann's mineral was from the Turginsk copper mine near Bogoslovsk, in the Ural, and from the Kolyvan district, in the Altai; that of Breithaupt, from near Hof in Bavaria, and Siegen in Prussia; found also with limonite at Dusseldorf in Prussia; at the Louisa mine, Horhausen. In the United States it occurs abundantly, and very large botryoidal massive, at the limonite ore bed of Salisbury, Ct., as detected by Prof. Brush (Am. J. Sci., II. xliv. 219), usually constituting the exterior layer of the limonite, sometimes an inch or more thick. The line of demarcation between it and the limonite is very distinct, and separation along it is often easy.

Artif.—E. Davies has shown that the ordinary precipitate of hydrate of iron, on being boiled in water, may have its water reduced to 3·52 p. c. (J. Ch. Soc., II. iv. 69); and Rodman (l. c.) has, by the same method, reduced it to 2 p. c., showing that the water varies with the temperature of origin; and, as Davies observes, no great heat is needed to make thus anhydrous hematite.

203. DIASPORE. Diaspore *Haüy*, Tr., iv. 1801. Blättricher Hydrargillit *Hausm.*, Handb., 442, 1813. Hydrate of alumine.

Orthorhombic. $I \wedge I$=93° 42¾′, $O \wedge 1\text{-}\bar{i}$=147° 12½′; $a : b : c$=0·64425 : 1 : 1·067. Observed planes: vertical, I, $i\text{-}\breve{i}$, $i\text{-}\bar{i}$, $i\text{-}\breve{\frac{3}{2}}$, $i\text{-}2$, $i\text{-}\breve{3}$, $i\text{-}\breve{5}$, $i\text{-}\bar{\frac{3}{2}}$, $i\text{-}2$; domes, $1\text{-}\breve{i}$, $\frac{1}{2}\text{-}\breve{i}$, $\frac{3}{8}\text{-}\breve{i}$; octahedral, 1, 2-2, 1-2, $\frac{5}{2}\text{-}\overline{10}$, $\frac{9}{2}\text{-}\frac{9}{2}$, 1-3, $4\text{-}\frac{14}{3}$.

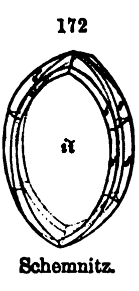
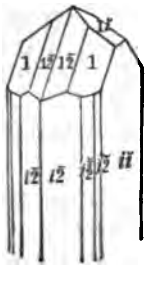
172



Schemnitz.

173



Crystals usually thin, flattened parallel to $i\text{-}\breve{i}$; sometimes acicular; commonly implanted. Cleavage: $i\text{-}\breve{i}$ eminent; $i\text{-}2$ less perfect. Occurs foliated massive and in thin scales; sometimes stalactitic.

H.=6·5—7. G.=3·3—3·5; 3·4324, Haüy: 3·452, Dufrenoy; 3·30—3·34, fr. Schemnitz. Lustre brilliant and pearly on cleavage-face; elsewhere vitreous. Color whitish, grayish-white, greenish-gray, hair-brown, yellowish, to colorless; sometimes violet-blue in one direction, reddish plumb-blue in another, and pale asparagus-green in a third. When thin, translucent—subtranslucent. Very brittle.

Comp.—$\bar{\rm Al}\,\dot{\rm H}$=85·1 alumina, 14·9 water=100. Analyses: 1, 2, Dufrénoy (Ann. d. M., III x. 577, 1836); 3, Hess (Pogg., xviii. 255); 4, Damour (C. R., xxi. 322); 5, Löwe (Pogg., lxi. 307); 6, 7, J. L. Smith (Am. J. Sci., II. xi. 58); 8, Damour (L'Institut, 1853, 78); 9, C. T. Jackson (Am. J. Sci., II. xlii. 108); 10, S. B. Sharples (Priv. contrib.):

Anal. 2 was made on the mineral of anal. 1 after removing the iron by sulphuric acid.

Pyr., etc.—In the closed tube decrepitates strongly, separating into pearly white scales, and at a high temperature yields water. The variety from Schemnitz does not decrepitate. Infusible; with cobalt solution gives a deep blue color. Some varieties react for iron with the fluxes. Not attacked by acids, but after ignition becomes soluble in sulphuric acid.

Obs.—Commonly found with corundum or emery in dolomite, chlorite schist, and other crystalline rocks, in nests, or as implanted crystals on corundum and other minerals. Occurs near Kossoibrod, district of Katharinenburg in the Ural, in granular limestone with emery; at Schemnitz in veins between dolomite and limestone; at Broddbo near Fahlun; with corundum in dolomite in Campo Longo, near Dazio Grande, in the Canton of Tessin in Switzerland; at Gumuch-dagh and Manser, Asia Minor, and the Grecian islands Naxos, Samos, and Nicaria, with emery, as detected by J. L. Smith; with topaz and margarodite at Trumbull, Ct., but rare; with corundum and margarite at Newlin, Chester Co., Pa.; at the emery mines of Chester, Mass., in large plates and crystals. Exists also as an impurity in some zeolites (Scheerer, Pogg., cviii. 430).

The above angles are from Kokscharof (Min. Russl., iii. 169). Marignac obtained by measurement 1-ĭ∧1-ĭ=117° 46′, i-2∧i-2=130°, 1-2∧1-2=151° 36′ and 116° 38′; Phillips, i-2∧i-2=129° 48′; Kenngott, i-2∧i-2=129° 32′; Haidinger, i-2∧i-2=129° 54′, 1-2∧1-2=151° 54′.

Diaspore was named by Haüy from διασπείρω, to scatter, alluding to the usual decrepitation before the blowpipe. Le Lièvre, as Haüy states, first made known the species, having found it at a mineral-dealer's in Paris, and given it to Vauquelin for analysis. Its original locality is not known, but is supposed to have been the Urals. Vauquelin obtained alumina 80, oxyd of iron 3, water 16 to 18=100 (Haüy, Tr., l. c., and Ann. Ch., xlii. 113, 1802).

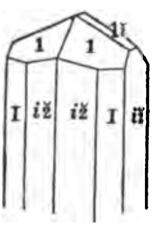
174



In prisms longitudinally striated, and often flattened intc scales or tables parallel to the shorter diagonal. Cleavage: brachydiagonal, very perfect. Also fibrous; foliated or in scales; massive; reniform; stalactitic.

H.=5—5·5. G.=4·0—4·4; 4·37, crystals from Lostwithiel in Cornwall, Yorke. Lustre imperfect adamantine. Color yellowish, reddish, and blackish-brown. Often blood-red by transmitted light. Streak brownish-yellow—ochre-yellow.

Var.—1. In thin scale-like or tabular crystals, usually attached by one edge. Such is the original *Göthite* (*Pyrrhosiderite* or *Rubinglimmer*) of Siegen.

2. In acicular or capillary (not flexible) crystals, or slender prisms often radiately grouped: the *Needle-Ironstone* (*Nadeleisenstein*). It passes into (*b*) a variety with a velvety surface: the *Przibramite* (*Sammetblende*) of Przibram is of this kind.

(*c*) *Onegite* is acicular göthite penetrating quartz, like rutile, from an island in L. Onega, Russia, where it was found in loose stones, in 1800, by Mr. Armstrong, an Englishman. It has also been called *Fullonite*, after Mr. Fullon, a brother-in-law of Mr. A., who also possessed specimens.

3. Columnar or fibrous.

4. Scaly-fibrous, or feathery columnar, the lines consisting of more or less distinct scales, somewhat like plumose mica; the *Lepidocrocite* (fr. λεπις, *scale*, and κροκις, *fiber*).

5. According to Hausmann, compact massive, with a flat conchoidal fracture, liver-brown to blackish-brown and rust-brown color; and sometimes reniform or stalactitic.

6. Disseminated microscopic crystals of göthite are one source of the frequent *aventurine* and opalescent character of specimens of different feldspars (see p.

Comp.—$\overline{\mathrm{Fe}}\,\dot{\mathrm{H}}$=Sesquioxyd of iron 89·9, water 10·1=100. Analyses: 1–3, v. Kobell (J. pr. Ch., ı. 181, 319); 4, Brandes (Nögg. Geb. in Rheinl. Westph., i. 358); 5, 6, v. Kobell (l. c.); 7, Plattner (J. pr. Ch., xix. 103); 8, Yorke (Phil. Mag., III. xxvii. 264):

8. Lostwithiel, *cryst.*	89·55	0·16	10·07	0·28=100·06 Yorke.

Göthite from near Marquette gave G. J. Brush 10·47 $\dot{\mathrm{H}}$ (Am. J. Sci., II. xxxvii. 271). The Amberg mineral (anal. 5) has been called *stilpnosiderite;* but Ullmann, who gave this name, found for his mineral the composition of limonite (q. v.)

Pyr., etc.—In the closed tube gives off water and is converted into red sesquioxyd of iron. With the fluxes like hematite; most varieties give a manganese reaction, and some, treated in the forceps in O.F., after moistening in sulphuric acid, impart a bluish-green color to the flame (phosphoric acid). Soluble in muriatic acid.

Obs.—Found with the other oxyds of iron, especially hematite or limonite. Occurs at Eiserfeld near Siegen, in Nassau, in lamelliform and foliated crystallizations of a hyacinth-red color, with limonite; at Zwickau in Saxony; Oberkirchen in Westerwald, etc.; near Clifton in Gloucestershire, near Bristol, England; in Cornwall, near Botallack and Lostwithiel, some of the crystals 1½—2 in. long and ¾ in. across; in Somersetshire, at the Providence iron mines.

In the U. States, at the Jackson Iron Mtn., near Marquette, L. Superior, in lamelliform crystals; in Penn., near Easton, the var. lepidocrocite with limonite; in California, at Burns Creek, Mariposa Co., in quartz; in Oregon, 16 m. from Portland.

Named *Göthite* after the poet philosopher Göthe; and *Pyrrhosiderite* from πυῤῥος, *fire-red*, and σίδηρος, *iron*. The name *Onegite* has priority, but it was given without a proper description, and for 25 years the nature of the mineral was unknown.

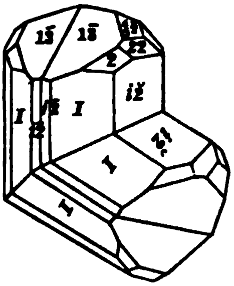
175.



Twins: composition-face $1\text{-}\breve{i}$. Cleavage: $i\text{-}\breve{i}$ very perfect, I perfect. Crystals longitudinally striated, and often grouped in bundles. Also columnar; seldom granular; stalactitic.

H.=4. G.=4·2—4·4. Lustre submetallic. Color dark steel-gray—iron-black. Streak reddish-brown, sometimes nearly black. Opaque; minute splinters, sometimes brown by transmitted light. Fracture uneven.

Comp.—$\overline{\text{Mn}}\,\dot{\text{H}}$=Sesquioxyd of manganese 89·8 (=Mn 62·5, O 27·3), water 10·2=100. Analyses: 1, Arfvedson (Schw. J., xxvi. 262); 2, Gmelin (ib., xlii. 208); 3, 4, Turner (Edinb. Trans., 1828); 5, How (Phil. Mag., IV. xxxi. 166):

	Mn	O	$\dot{\text{H}}$	
1. West Gothland	89·92		10·08	Arfvedson.
2. Ilefeld	62·86	27·64	9·50	Gmelin.
3. "	62·68	27·22	[10·10]	Turner.
4. "	62·77	27·13	[10·10]	Turner.
5. Cheverie	86·81		10·00, gangue 1·14, $\bar{\text{Fe}}$, $\dot{\text{Ba}}$, loss 2·05	How.

Pyr., etc.—In the closed tube yields water; otherwise like braunite.

Obs.—Occurs in veins traversing porphyry, associated with calcite and barite, at Ilefeld in the Harz; Ilmenau and Oehrenstock in Thuringia; Undenaes in Sweden; Christiansand in Norway; Cornwall, at various places, occurring crystallized at Botallack mine, St. Just; Callington and at the Royal iron mines; also in Cumberland, Devonshire, Somerset; Aberdeenshire, Scotland: near Ross and elsewhere in Ireland.

In Nova Scotia, at Cheverie, Hants Co., and Walton; also 10 m. W. of Walton, where it forms a bed of conglomerate, along with quartz pebbles. In New Brunswick, at Shepody mountain, Albert Co.; Tattagouche R., Gloucester Co.; Upham, King's Co.; and Dalhousie, Restigouche Co.

Newkirkite of Thomson, from Newkirchen in Alsace, according to Lettsom, is nothing but manganite.

Alt.—By loss of water changes to pyrolusite, hausmannite, or braunite. *Varvicite* of R. Phillips, from Warwickshire, is considered an altered manganite, consisting largely of pyrolusite. Breithaupt observed a crystal with nearly the angles of manganite, giving $I \wedge I=80° \ 24'$ and $99° \ 16'$. H.=2·5—3. G.=4·283—4·623.

Limn *Glock.*, Syn., 62, 1847.

Usually in stalactitic and botryoidal or mammillary forms, having fibrous or subfibrous structure; also concretionary, massive; and occasionally earthy.

H.=5–5·5. G.=3·6–4. Lustre silky, often submetallic; sometime dull and earthy. Color of surface of fracture various shades of brown commonly dark, and none bright; sometimes with a nearly black varnish like exterior; when earthy, brownish-yellow, ochre-yellow. Streak yellowish-brown.

Var.—(1) *Compact.* Submetallic to silky in lustre; often stalactitic, botryoidal, etc. (2 *Ochreous* or earthy, brownish-yellow to ochre-yellow, often impure from the presence of clay sand, etc. (3) *Bog ore.* The ore from marshy places, generally loose or porous in texture, ofte petrifying leaves, wood, nuts, etc. (4) *Brown clay-ironstone*, in compact masses, often in concretionary nodules, having a brownish-yellow streak, and thus distinguishable from the clay-iron stone of the species hematite and siderite; it is sometimes (*a*) *pisolitic*, or an aggregation of con cretions of the size of small peas (Bohnerz *Germ.*); or (*b*) *oolitic.*

Only part of stalactitic limonite, brown or yellow ochre, bog ore, and clay-ironstone belong her the water present sometimes much exceeding that of limonite, so as to make them of the specie *xanthosiderite* or *limnite.* But since in the determinations of the water analysts have not alway separately estimated the organic ingredients, it is at present impossible to refer the analyses i all cases to their true places.

Kaliphite of Ivanoff is a mixture of limonite, oxyd of manganese, silicate of zinc and lim from Hungary.

Comp.—F̶e^2 Ḣ^3=Sesquioxyd of iron 85·6, water 14·4=100. In the bog ores and ochres, sand clay, phosphates, oxyds of manganese, and humic or other acids of organic origin are very commo impurities.

Analyses: 1, Ullmann (Ueb., 314, 1814); 2, 3, v. Kobell (J. pr. Ch., i. 181, 319); 4, Beck (Mi N. Y., 33); 5, Amelung (Ramm. Min. Ch., 149); 6, Schönberg (J. pr. Ch., xix., 107); 7, C. Bergemann (Verh. nat. Ver. Bonn, xvi. 127); 8, Litton (Rep. G. Mo., 1855); 9, C. S. Rodman (priv. contrib.); 10–13, Schenck (Ann. Ch. Pharm., xc. 123):

13. " "	70·46	11·12	13·04	5·88=100·50 Schenck.	

A concretionary ore from Staatswald Hardt, Wurtemberg, afforded A. Müller (J. pr. Ch., lvii. 124) 0·05 p. c. of chromic acid, and 0·08 of vanadic; and traces of titanium, sulphur, and arsenic have been found in others.

The organic acids sometimes amount to 12—15 p. c., as in the following: 1, T. S. Hunt (Rep. G. Can., 513, 1863); 2, 3, Wiegmann (Preischr. Torfes, 75, 76, 1837):

	$\bar{\text{F}}\text{e}$	$\dot{\text{M}}\text{n}$	$\dot{\text{H}}$	$\ddot{\text{S}}\text{i}$	$\bar{\text{P}}$	Humic acid.

3. " " "	68·5	1·5	10·5	——	7·0	12·5=100 Wiegmann.

The ochre analyzed by Hunt was from a bed in the soil having an extent of many acres; the color light brownish-yellow. It may be a mixture of limonite and a hydrous species containing oxyd of iron combined with organic acids. Hunt suggests that it should be made a distinct species; and when the exact nature of the organic acids is determined, this may properly be done.

In other analyses of bog ores from Vaudreuil and other places in Canada, Hunt found 16·50 to 23·65 p. c. of water and organic acids, but the proportion of the two was not determined. For other so-called limonite, bog ores, and ochres, see XANTHOSIDERITE and LIMNITE.

Pyr., etc.—Like göthite. Some varieties give a skeleton of silica when fused with salt of phosphorus, and leave a siliceous residue when attacked by acids.

Obs.—Limonite occurs in secondary or more recent deposits, in beds associated at times with barite, siderite, calcite, aragonite, and quartz; and often with ores of manganese; also as a modern marsh deposit.

It is in all cases a result of the alteration of other ores, through exposure to moisture, air, and carbonic or organic acids; and is derived largely from the change of pyrite, siderite, magnetite, and various mineral species (such as mica, augite, hornblende, etc.), which contain iron in the protoxyd state. It consequently occupies, as a bog ore, marshy places, over most countries of the globe, into which it has been borne by streamlets from the hills around; and in the more compact form it occurs in stalactites as well as in tuberose and other concretionary forms, frequently making beds in the rocks which contain the minerals that have been altered into it. In moist places where a sluggish streamlet flows into a marsh or pool, a rust-yellow or brownish-yellow deposit often covers the bottom, and an iridescent film the surface of the water: the deposit is a growing bed of bog ore. The iron is transported in solution as a protoxyd carbonate in carbonated waters, a sulphate, or as a salt of an organic acid. The limonite beds of the Green Mountain region were shown by Percival (Rep. G. Conn., 132, Am. J. Sci., II. ii. 268) to be altered beds of pyritiferous micaceous and argillaceous schist; and the same is held by Lesley as true also of the other beds of the Atlantic border, from New England and New York, through Pennsylvania (Mt. Alto region and others), to Tennessee and Alabama (Proc. Am. Ac. Philad., 463, 1864, Am. J. Sci., II. xl. 119).

Abundant in the United States. A few only of its localities are here mentioned; reference may be made to the various geological reports for complete lists. Extensive beds exist at Salisbury and Kent, Conn., also in the neighboring towns of Beekman, Fishkill, Dover, and Amenia, N. Y., and in a similar situation north; at Richmond and Lenox, Mass.; at Hinsdale as the cement in a conglomerate quartz rock; in Vermont, at Bennington, Monkton, Pittsford, Putney, and Ripton.

Limonite is one of the most important ores of iron. The pig iron, from the purer varieties, obtained by smelting with charcoal, is of superior quality. That yielded by bog ore is what is termed *cold short*, owing to the phosphorus present, and cannot therefore be employed in the manufacture of wire, or even of sheet iron, but is valuable for casting. The hard and compact nodular varieties are employed in polishing metallic buttons, etc.

Named *Limonite* from λειμών, *meadow*. Ullmann's name, *Stilpnosiderite*, from στιλπνός, *shining*, has priority; but the ore is characteristically not a shining ore, although sometimes with a lustrous, varnish-like exterior. The name *limonite* was first appropriated especially to the *bog* ores by Hausmann in 1813. But most bog ores are of the above species, and Beudant, recognizing this, in 1832 used limonite for the *bog* as well as other limonite.

Alt.—By deoxydation through organic matter, if carbonic acid is present, may form siderite ($\dot{\text{F}}\text{e}\,\ddot{\text{C}}$). By losing water becomes hematite ($\bar{\text{F}}\text{e}$). Hematite occurs as pseudomorphs after limonite. This species forms numerous pseudomorphs of other species.

207. XANTHOSIDERITE. Gelbeisenstein (fr. Goslar) *Hausm.*, Handb., 279, 1813. Xanthosiderit (fr. Ilmenau) *E. E. Schmid*, Pogg., lxxxiv. 495, 1851. Yellow Ochre pt. Bo Ore pt.

In fine needles or fibres, stellate and concentric. Also as an ochre.

H.=2·5 when in needles. Lustre silky or greasy; also pitch-like; als earthy. Color in needles golden-yellowish, brown to brownish-red; as an ochre, yellow of different shades, more or less brown, sometimes reddish. Streak ochre-yellow.

Comp.—$\overline{\mathrm{Fe}}\,\dot{\mathrm{H}}^2$=Sesquioxyd of iron 81·6, water 18·4=100. Analyses: 1, Hausmann (Gilb. Ann., v. 21, 1811); 2, 3, Schmid (l. c.); 4, Murray (Ramm. Min. Ch., 150); 5, Haughton (Phil. Mag., IV. xxxii. 220):

	$\overline{\mathrm{Fe}}$	$\overline{\mathrm{Mn}}$	$\overline{\mathrm{Al}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{Si}}$
1. Goslar, Harz	69·00	——	2·50	16·39	4·00, $\dot{\mathrm{F}}\mathrm{e}\,\dddot{\mathrm{S}}$ 8·05=99·84 Hausm.
2. Ilmenau, *yellow* [a]	74·96	1·82	1·32	15·67	2·51=96·28 Schmid.
3. " *brown* [a]	75·00	1·33	1·51	14·10	5·02=96·96 Schmid.
4. Hüttenrode, *brown*	81·41	——	——	17·96	0·17, $\ddot{\mathrm{C}}$ 0·46=100 Murray.
5. Kilbride, Ireland.	77·15	——	*tr.*	20·43	0·30, $\dot{\mathrm{P}}$ 1·60=99·48 Haughton

[a] Loss due to undetermined lime, magnesia, alkalies, antimony, lead, and bismuth, present as impurities.

Haughton found no organic matter, protoxyd of iron, or sulphur in his analyses. Half the water in Hausmann's analysis must have belonged to the sulphate of iron, or else the mineral analyzed by him could not have corresponded to the formula given.

Pyr., etc.—Like those of limonite.

Obs.—Associated with manganese ores at Ilmenau, in silky needles, etc.; as an ochre near Goslar, Bruchberg, Elbingerode in the Harz; as a pitchy ore at Kilbride, Wicklow Co., Ireland, along with limonite and psilomelane.

Several analyses of bog ore apparently accord with those of xanthosiderite. But the amount of water given actually includes whatever was driven off on ignition, and no examination was made for organic acids. See under LIMONITE.

Artif.—The hydrate, $\overline{\mathrm{Fe}}\,\dot{\mathrm{H}}^2$, is formed when oxyd of iron is precipitated from hot solutions of its salts; and, according to Gmelin, also from cold solutions.

208. BEAUXITE. Alumine hydratée de Beaux *Berthier*, Ann. d. M., vi. 531, 1821. Beauxite *Dufr.*, Min. (ii. 347), iii. 799, 1847. Bauxite *Deville*, Ann. Ch. Phys., III. lxi. 309, 1861. Wocheinite *A. Flechner*, ZS. G., xviii. 181, 1866, Jahrb. G. Reichs., 1866.

In round concretionary disseminated grains. Also massive oölitic; and earthy, clay-like.

G.=2·551, fr. Wochein, v. Lill. Color whitish, grayish, to ochre-yellow, brown, and red.

Var.—1. In concretionary grains, or oolitic; *beauxite*. 2. Clay-like, *wocheinite*; the purer kind grayish, clay-like, containing very little oxyd of iron; also red from the oxyd of iron present.

Comp.—$(\overline{\mathrm{Al}}, \overline{\mathrm{Fe}})\,\dot{\mathrm{H}}^2$; with $\overline{\mathrm{Al}} : \overline{\mathrm{Fe}}=3:1$,=Alumina 50·4, sesquioxyd of iron 26·1, water 23·5 =100; without $\overline{\mathrm{Fe}}$,=$\overline{\mathrm{Al}}$ 74·1, water 25·9=100. Berthier considered the iron an impurity. Analyses: 1, Berthier (l. c.); 2, Deville (Ann. Ch. Phys., III. lxi. 309); 3, Berthier (l. c., v. 133, 1820); 4, v. Lill (Jahrb. G. Reichs., Verh. 1866, 11):

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{H}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$
1. Beaux	——	52·0	27·6	20·4	——	——=100 Berthier.
2. "	——	55·4	44·6		——	——=100 Deville.
3. Senegal	2·0	40·0	33·60	24·7	——	——, $\overline{\mathrm{Cr}}$ *tr.*=100·3 Berthier.
4. Wochein	6·29	64·24	2·40	25·74	0·85	0·38, $\dddot{\mathrm{S}}$ 0·20, $\dot{\mathrm{P}}$ 0·46, $\dot{\mathrm{K}}$, $\dot{\mathrm{Na}}$, $\dot{\mathrm{Li}}$ *tr.*=100·56 Lill.

In the last, which has been called *wocheinite* (although at first referred to beauxite), if the 6·29 $\ddot{\mathrm{Si}}$ are present in the condition of kaolinite, and this and the other ingredients are rejected as impurities, the remainder corresponds approximately to $\overline{\mathrm{Al}}\,\dot{\mathrm{H}}^2$. But if the $\ddot{\mathrm{Si}}$ is in the condition of allophane, it will require 13 p. c. of the water, and the wocheinite remaining would be essentially identical with *diaspore*. A red variety from Wochein contained 8·8 $\overline{\mathrm{Fe}}$ and 58·02 $\overline{\mathrm{Al}}$.

The following are analyses by Deville (l. c.) of what he regards as impure varieties of beauxite all but one of which contain only water enough for a species of the diaspore group:

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{Ti}}$	$\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$
1. Beaux, *white*	21·7	58·1	3·0	[14·0]	3·2	*tr.*=100
2. Revest, *bnh.-red*	2·8	57·6	25·3	10·8	3·1	0·4=100
3. Allauch, *oolitic*	4·8	55·4	24·8	11·6	3·2	0·2=100
4. Beaux	——	30·3	34·9	22·1	—	12·7=100
5. Calabria	2·0	33·2	[48·8]	8·6	1·6	——, corundum 5·8=100.

Obs.—From Beaux (sometimes spelt Baux), near Arles, France, disseminated in grains in compact limestone, and also oolitic; also at Revest, near Toulon, brown to dark-red, and massive, regarded as an iron ore; at Allauch, Dept. of Var, France, massive, oolitic, with a base of like nature, cemented by some carbonate of lime, the most common variety; at Hügel, in the Commune of Beaux, a hard and firm variety; at Calabre, massive. The *wocheinite* occurs in Styria, between Feistritz and Lake Wochein, in a deposit 12 feet thick, the junction of the Trias and Jurassic formations, part of it red from the presence of oxyd of iron. The purest beauxite is used for the manufacture of aluminum, and is called *aluminum ore.*

209. **ELIASITE.** Uranisches Pittin-Erz, Pittinus inferior, *Breith.*, Handb., 901, 1847. Eliasit *Haid.*, Jahrb. G. Reichs., iii. No. 4, 124, 1852. Pittinit *Herm.*, J. pr. Ch., lxxvi. 322, 1859.

In amorphous masses, more or less resin-like in aspect, or like gum. H.=3·5—4·5. G.=4·0—5·0. Lustre greasy or resinous. Color dull; reddish-brown, with thin edges hyacinth-red; also black. Streak wax-yellow to orange; of the black var., olive-green. Subtranslucent to opaque. Fracture somewhat uneven, slightly conchoidal.

Var.—1. *Eliasite.* Somewhat resin-like in aspect; G.=4·087—4·237, v. Zepharovich. Color dull reddish-brown.

2. *Pittinite.* Color black; streak olive-green; lustre greasy submetallic; G.=4·8—5·0, Breith.; 5·16, Herm.

Comp.—$\dddot{\mathrm{U}}\,\dot{\mathrm{H}}^{3}$, with opal silica and other impurities. O ratio for $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, as deduced by Hermann, in *eliasite*, 2 : 24 : 5 : 18; in *pittinite*, 2 : 24 : 5 : 16. These numbers correspond very nearly to the above formula, and make the species analogous to xanthosiderite.

Analyses: 1, F. Ragsky (Pogg., IV. Ergzonz., 348, 1853); 2, Hermann (J. pr. Ch., lxxvi. 326):

	$\dddot{\mathrm{U}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Pb}}$	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{P}}$	$\dot{\mathrm{H}}$
1. *Eliasite*	61·33	6·63	3·09	2·20	4·62	5·13	0·84	10·68, $\dddot{\mathrm{Al}}$ 1·17, $\dot{\mathrm{Fe}}$ 1·09, $\ddot{\mathrm{C}}$ 2·52, As *tr.* =99·30 Ragsky.
2. *Pittinite*	68·45	4·54	2·26	0·55	2·51	5·00	*tr.*	10·06, $\dddot{\mathrm{Bi}}$ 2·67, insol. 3·20=99·24 H.

The carbonic acid in anal. 1 may be combined with lime and part of the magnesia, making 5·7 p. c. of impurity.

Pyr., etc.—Nearly as for *gummite.* Eliasite is soluble in muriatic acid.

Obs.—*Eliasite* is from the Elias mine, Joachimsthal, where it occurs with fluor, dolomite, pitchblende, etc; and *pittinite*, from Joachimsthal. This species may not be distinct from gummite.

210. **BRUCITE.** Native Magnesia (fr. N. Jersey) *A. Bruce*, Bruce's Min. J., i. 26, 1814 (with anal.). Hydrate of Magnesia *A. Aikin*, Min., 236, 1815, *Cleaveland*, Min., 429, 1822, *F. Pyr., etc.—In the closed tube gives off water, becoming opaque and friable, sometimes turning gray to brown. B.B. infusible, glows with a bright light, and the ignited mineral reacts alkaline to test paper. With cobalt solution gives the violet-red color of magnesia. The pure mineral is soluble in acids without effervescence.

Obs.—Brucite accompanies other magnesian minerals in serpentine, and has also been found in limestone. Occurs in considerable veins traversing serpentine, at Swinaness in Unst, one of the Shetland Isles, where it is sometimes found in regular crystals; at Pyschminsk in the Urals; at Houjot in France; near Filipstadt in Wermland, in Sweden, in roundish masses in limestone. It occurs at Hoboken, N. J., opposite the city of New York, in seams in serpentine; in Richmond Co., N. Y.; on the peninsula east of New Rochelle, Westchester Co., N. Y.; at Wood's mine, Texas, Pa., in large plates or masses, and often crystallizations several inches across; at Low's mine, with hydromagnesite.

The angles and f. 177 given above are from Texas crystals, as measured by Hessenberg (Min. Not., iv. 42). G. Rose obtained from the same, $O \wedge R = 120°$, $O \wedge \frac{1}{2}R = 149° 40' - 150° 51'$, $R \wedge -\frac{1}{2}R = 90°$. The author gave the following measurements of a minute crystal from Low's mine (f. 176) in his last edit.: $O \wedge R = 119° - 119° 55°$, $O \wedge 2R = 105° 30'$, $R \wedge R$ (by calc.)$= 82° 15'$

The fibrous variety (nemalite) occurs at Hoboken, and Xettes in the Vosges.

Named after A. Bruce, an early American mineralogist, who first described the species.

Alt.—Becomes white, pulverulent, and carbonated on exposure, and also crystallized, constituting then the mineral hydromagnesite; the latter is sometimes in pseudomorphous crystals after brucite.

211. PYROCHROITE. Pyrochroit *L. J. Igelström*, Pogg., cxxii. 181, 1864, Œfv. Ak. Stockh., 1864, 205, 1865.

Foliated, like brucite.

H.=2·5. Lustre pearly. Color white; but changing on exposure to bronze, and then to black. In thin pieces transparent, and having a flesh-red color by transmitted candle-light.

Comp.—$\dot{\mathrm{Mn}}\,\dot{\mathrm{H}}$, or $(\dot{\mathrm{Mn}}, \dot{\mathrm{Mg}})\,\dot{\mathrm{H}}$. $\dot{\mathrm{Mn}}\,\dot{\mathrm{H}}$=Protoxyd of manganese 79·8, water 20·2=100. Analysis: Igelström (l. c.):

$\dot{\mathrm{Mn}}$ 76·40 $\dot{\mathrm{Mg}}$ 3·14 $\dot{\mathrm{Ca}}$ 1·27 $\dot{\mathrm{Fe}}$ 0·01 $\dot{\mathrm{H}}$ 15·35 $\ddot{\mathrm{C}}$ [3·834]

Pyr., etc.—In a matrass a small piece becomes at surface verdigris-green, then dirty green, and finally brownish-black. Yields water. B.B. reactions of manganese. In muriatic acid forms easily a clear colorless solution.

Obs.—Occurs in veins 1 to 2 lines broad in magnetite at Paisberg in Filipstadt, Sweden.

Kenngott refers here (Jahrb. Min., 1866, 440) a mineral which Wiser had announced as a hydrous carbonate of manganese (Wasserhaltiges Kohlensaures Mangan), and which Haidinger (Handb., 493, 1845) named *Wiserite*. It is described as yellowish-white to gray in color, pearly to silky in lustre, fibrous in structure, and as coming from Gonzen near Sarganz, the Canton of St. Gall, in Switzerland, where it is found in seams in a granulitic hausmannite, with rhodochrosite. Even if identical with pyrochroite in composition, it was so imperfectly and incorrectly described that Igelström's name should stand for the species.

212. GIBBSITE. Wavellite (fr. Richmond) *C. Dewey*, Am. J. Sci., ii. 249, 1820;=Water and Alumina, *id.*, ib., iii. 239, 1821. Gibbsite *J. Torrey*, N. Y. Med. Phys. J., i. No. 1, 68, April, 1822. Hydrargillite, Gibbsite of Torrey, *Cleavel.*, 224, 782, 1822. Hydrargillite (fr. Ural) *G. Rose*, Pogg., xlviii. 564, 1839.

Hexagonal, Koksch.; monoclinic, Descl. In small hexagonal crystals with replaced lateral edges. $O \wedge R = 92° 28'$, $O \wedge \frac{1}{3}R = 97° 22'$, $O \wedge -\frac{1}{2}R = 94° 55'$, Koksch. Planes vertically striate. Cleavage: basal or O eminent. Occasionally in lamello-radiate spheroidal concretions. Usually stalactitic, or small mammillary and incrusting, with smooth surface, and often a faint fibrous structure within.

H.=2·5–3·5. G.=2·3–2·4; 2·385, fr. Richmond, B. Silliman, Jr.; 2·287, Ural, Hermann. Color white, grayish, greenish, or reddish-white; also reddish-yellow when impure. Lustre of O pearly; of other faces vitreous; of surface of stalactites faint. Translucent; sometimes transparent in crystals. A strong argillaceous odor when breathed on. Tough.

Var.—1. In crystals; the original *hydrargillite*. 2. Stalactitic; *gibbsite*.

Comp.—$\bar{\mathrm{Al}}\,\dot{\mathrm{H}}^3$=Alumina 65·6, water 34·4=100. Analyses: 1, Torrey (l. c.); 2, B. Silliman, Jr. (Am. J. Sci., II. vii. 411); 3, 4, Smith & Brush (Am. J. Sci., II. xvi. 51, 1853); 5, Hermann (J. pr. Ch., xl. 11); 6, v. Kobell (J. pr. Ch., xli., and l. 491); 7, v. Hauer (Jahrb. G. Reichs., iv. 397):

6. Villa Rica, "	65·6	——	——	34·4	——	——	=100 Kobell.
7. " "	64·35	——	——	35·65	——	*tr.*	=100 Hauer.

Dewey found (l. c.) 33–36 p. c. of water, with "little besides alumine left."

Hermann states (J. pr. Ch., xl. 32, xlii. 1) that a "gibbsite" from Richmond, Mass., afforded him $\overset{\cdot\cdot}{\dddot{P}}$ 37·62, $\bar{\dddot{\text{A}}}\text{l}$ 26·66, $\dot{H}$ 35·72=100. But the true gibbsite has since been analyzed anew by Silliman, Jr., and by Smith & Brush, without finding more than a trace of phosphoric acid, sustaining the original analysis of Torrey. This at least is certain, that gibbsite is a hydrate, and if a phosphate occurs also at Richmond, that phosphate is *not* gibbsite. Rose's hydrargillite (found crystallized in the Urals) is identical in composition with gibbsite.

Pyr., etc.—In the closed tube becomes white and opaque, and yields water. B.B. infusible, whitens, and does not impart a green color to the flame. With cobalt solution gives a deep-blue color. Soluble in concentrated sulphuric acid.

Obs.—The crystallized gibbsite was discovered by Lissenko in the Schischimskian mountains near Slatoust in the Ural; it occurs, according to Kokscharof, in cavities in a talcose schist containing much magnetite. The larger crystals were 1 to 2 in. long. With corundum at Gumuchdagh, Asia Minor; also on corundum at Unionville, Pa.; in Brazil, resembling wavellite. The stalactitic occurs at Richmond, Mass., in a bed of limonite; also at Lenox, Mass.; at the Clove mine, Union Vale, Duchess Co., N. Y., on limonite; in Orange Co., N. Y.

Named after Col. George Gibbs, the original owner (after extensive foreign travel) of the large Gibbs' cabinet of Yale College. Cleaveland calls the Richmond mineral *hydrargillite* on p. 224 of his mineralogy, but on p. 782 adopts Torrey's name *gibbsite*.

Kokscharof states that the Ural crystals are optically uniaxial, and hence rhombohedral (Bull Ac. St. Pet., v. 372); Descloizeaux that they are optically monoclinic (C. R., lxii. 987).

213. LIMNITE. Limonite pt. Yellow Ochre pt. Bog Ore pt. Brown Iron Ore (Brauneisenstein) pt. Quellerz *Herm.*, J. pr. Ch., xxvii. 53.

Massive. In stalactites or tuberose, resembling limonite. Also as an earthy yellow ochre.

H., G., and other physical characters same nearly as for limonite. The darker colored kinds usually more yellowish-brown, the lighter rust-yellow.

Var.—1. Submetallic or pitch-like in lustre, brownish-black in color. 2. Ochreous, yellow.

Comp.—$\overline{\text{Fe}}\,\dot{H}^3$=Oxyd of iron 74·8, water 25·2=100. Analyses: 1, A. H. Church (J. Ch Soc., II. iii. 214); 2, 3, Hermann (l. c.); 4, Karsten (Karst. Arch., xv. 1):

	$\overline{\text{Fe}}$	$\overline{\text{Mn}}$	$\dot{H}$	$\overset{\cdot\cdot}{\dddot{P}}$	Humic acid
1. Cornwall, *stalact.*	73·73	—	24·40	—	—, loss, etc., 1·87=100 Church.
2. Novgorod, *bog ore* [a]	62·08	1·90	24·64	6·64	4·74=100 Herm.
3. " " [b]	61·14	3·10	27·74	5·86	2·16=100 Herm.
4. New York "	66·33	0·75	26·40 [c]	0·12	—, $\dot{\text{Fe}}$ 3·6, $\dddot{\text{Si}}$ 2·80=100 Karst.

[a] After excl. 47·50 sand. [b] After excl. 50·28 sand. [c] Including humic acid.

As the amount of organic acids in Karsten's analysis was not determined, its right to be included here is not certain.

Obs.—The Cornwall mineral is from the Botallack mine, and was stalactitic and of a rust-yellow color; G.=2·69. That of Novgorod, Russia, was a bog ore.

Named *limnite* from λιμνη, *marsh*. Glocker proposed this name as a substitute for limonite, on the alleged ground that the word limonite was of French extraction. As his limonite, or limnite, was bog ore exclusively, the name is appropriately used here. Hermann's name Quellerz alludes to its water or marsh origin.

214. HYDROTALCITE. Hydrotalkit *Hochstetter.*, J. pr. Ch., xxvii. 376, 1842. Völknerite *Herm.*, J. pr. Ch., xl. 11, 1847, xlvi. 257, 1849.

Hexagonal. Cleavage: basal, eminent; lateral, distinct. Also lamellar massive, or foliated, and somewhat fibrous.

H.=2. G.=2·04. Color white. Lustre pearly, and feel greasy. Translucent, or in thin folia transparent.

Comp.—$\bar{\dddot{\text{A}}}\text{l}\,\dot{H}^3+6\,\dot{\text{Mg}}\,\dot{H}+6\,\dot{H}=(\frac{1}{3}\,\bar{\dddot{\text{A}}}\text{l}+\frac{2}{3}\,\dot{\text{Mg}}^3)\,\dot{H}^3+2\,\dot{H}$=Alumina 16·8, magnesia 39·2, water 44·0=100. Corresponds to 1 of *gibbsite*+6 of *brucite*, with 6 $\dot{H}$ in addition.

Analyses: 1, Hermann (l. c.); 2, Hochstetter (l. c.); 3–6, Rammelsberg (Pogg., xcvii. 296):

	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{C}}$
1. Schischimsk	16·95	—	37·07	46·87	——=100 Hermann.
2. Snarum	12·00	6·90	36·80	32·06	10·54, insol. 1·20=99·60 Hochst.
3. "	19·25	—	37·27	41·59	2·61=100·72 Ramm.
4. "	17·78	—	38·18	[37·99]	6·05=100 Ramm.
5. "	18·00	—	37·30	[37·38]	7·32=100 Ramm.
6. "	18·87	—	37·04	37·38	7·30=100·59 Ramm.

Pyr., etc.—In the closed tube yields much water. B.B. infusible, but exfoliates somewhat, and gives out light. A weak rose-red with cobalt solution. With the fluxes intumesces and affords a clear colorless glass. The Snarum mineral reacts for iron.

Obs.—Occurs at the mines of Schischimsk, district of Slatoust, implanted on talc schist; at Snarum, Norway, in serpentine.

Named *hydrotalcite* in allusion to its resembling talc, but containing much more water, and *völknerite*, after Captain Völkner.

188

Houghite of Shepard (Am. J. Sci., II. xii. 210), from near Oxbow, and near Somerville in Rossie, St. Lawrence Co., New York, is hydrotalcite, derived from the alteration of spinel. The color is white; lustre faint, pearly. H.=2·5. G.=2·0—2·1. The crystals are in all conditions, from the pure spinel to octahedrons with rounded edges and pitted or irregular surfaces, and it also occurs in flattened nodules. The surfaces are sometimes soft and altered, when the edges or angles have the hardness of spinel. S. W. Johnson, who has redescribed the mineral, obtained in one analysis (Am. J. Sci., II. xii. 361), $\bar{\mathrm{Al}}$ 19·743, $\dot{\mathrm{Mg}}$ 36·292, $\ddot{\mathrm{C}}$ 8·458, insoluble spinel, etc., 8·264, silica 3·020, water (by diff.) 24·223. The whole loss by ignition in one trial was 40·86 p. c.; which would give 33 to 34 p. c. of water. It is associated with dolomite, spinel, phlogopite, graphite, and serpentine.

215. PYROAURITE. Pyroaurit *Igelström*, Œfv. Ak. Stockh., xxii. 608, 1865.

Hexagonal. In six-sided tables.
Color submetallic, gold-like. Subtranslucent.

Comp.—$\bar{\mathrm{Fe}}\,\dot{\mathrm{H}}^3 + 6\,\dot{\mathrm{Mg}}\,\dot{\mathrm{H}} + 6\,\dot{\mathrm{H}} = (\frac{1}{3}\,\bar{\mathrm{Fe}} + \frac{2}{3}\,\dot{\mathrm{Mg}}^3)\,\dot{\mathrm{H}}^3 + 2\,\dot{\mathrm{H}}$=Sesquioxyd of iron 23·9, magnesia 35·8, water 40·3=100. Corresponds to 1 of *limnite*+6 of *brucite*, with 6 $\dot{\mathrm{H}}$ in addition, differing from hydrotalcite in the presence of iron in place of aluminum. Analysis: Igelström (l. c.):

$\bar{\mathrm{Fe}}$ 23·92 $\dot{\mathrm{Mg}}$ 34·04 $\dot{\mathrm{H}}$ 34·56 $\ddot{\mathrm{C}}$ 7·24.

Pyr., etc.—Yields water. B.B. infusible. Perfectly soluble in muriatic acid.

Obs.—From the Longban iron-mine in Wermland.

216. GUMMITE. Feste Uranokker pt. *Wern.*, Min. Syst., 26, 1817, Hoffm. Min., iv. a, 279 Lichtes Uranpecherz *Freiesleben.* Uranisches Gummi-Erz *Breith.*, Uib., 60, 1830, Char., 218, 1832. Urangummi *Breith.*, Handb., 903, 1847. Phosphor-Gummit *Herm.*, J. pr. Ch., lxxvi. 327, 1859.

Amorphous. In rounded or flattened pieces, looking much like gum. H.=2·5—3. G.=3·9—4·20, Breith. Lustre greasy. Color reddish-yellow to hyacinth-red, reddish-brown. Streak yellow. Feebly translucent.

Comp.—$(\bar{\mathrm{U}}, \bar{\mathrm{Fe}})\,\dot{\mathrm{H}}^3$, with some opal silica, phosphate of lime, and other impurities. Hermann deduced the O ratio for $\dot{\mathrm{R}}^3$, $\bar{\mathrm{H}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, 2 : 24 : 5 : 26, or 1 : 1 for oxyds and water. Hence analogous to *limnite*, and sustaining the supposed close relation of uranium and iron. Analysis: Kersten (Schw. J., lxvi. 18):

$\bar{\mathrm{U}}$	$\bar{\mathrm{Mn}}$	$\dot{\mathrm{Ca}}$	$\ddot{\mathrm{Si}}$	$\overset{.....}{\mathrm{P}}$	$\dot{\mathrm{H}}$	F, As
72·00	0·05	6·00	4·26	2·30	14·75	*tr.*=99·36.

Some specimens contain traces of vanadic acid.

Pyr., etc.—Yields much water and a bituminous odor. With salt of phosphorus in O.F. gives a yellow bead, becoming green in R.F. (due to uranium), leaving an undissolved skeleton of silica.

Obs.—From Johanngeorgenstadt, with uraninite.

217. PSILOMELANE. Derb Brunsten pt. *Wall.*, Min., 268, 1747. Magnesia indurata pt. *Cronst.*, Min., 106, 1758. Schwarz Braunsteinerz pt. *Wern.*, Bergm. J., 1789, 386. Verhärtetes Schwarz-Braunsteinerz pt. *Emmerling*, Min., iv. 532, *Karsten*, Tab., 54, 1800. Verh. Schwarz-Manganerz pt. *Karst.*, Tab., 72, 1808. Schwarz-Eisenstein pt. *Wern.*, *v. Leonh.*, etc. Black Hematite, Black Iron Ore, Compact Black Manganese Ore. Hartmanganerz. Psilomelane *Haid.*, Trans. R. Soc. Edinb., 1827.

Massive and botryoidal. Reniform. Stalactitic.

H.=5—6. G.=3·7—4·7. Lustre submetallic. Streak brownish-black, shining. Color iron-black, passing into dark steel-gray. Opaque.

Comp.—$(\dot{Ba}, \dot{Mn})\,\ddot{Mn} + \bar{Mn} + n\,\dot{H}\,\ddot{Mn}\ [+aq]$; or, for the anhydrous kinds, $(\dot{Ba}, \dot{Mn})\,\ddot{Mn} + \bar{Mn}$. Each of these formulas is equivalent to simply R^2O^3. Rammelsberg writes for the mineral $(\dot{Ba}, \dot{Mn})\,\dot{Mn}^2 + \dot{H}$, with some $\ddot{Mn}$ as mixture. For the Elgersburg ore (anal. 7) Schmid deduces the formula $(\dot{Ba}\,\dot{Mn})\,\dot{Mn}^4 + 6\,\dot{H}$, which may be written $(\dot{Ba}, \dot{Mn})\,\dot{Mn} + 3\,\dot{H}\,\ddot{Mn} + 3\dot{H}$, equivalent to $\dot{R}^3O^3 + 3\,\dot{R}^2O^3 + 3\,\dot{H} = \dot{R}^2O^3 + \frac{3}{4}\,\dot{H}$. As the mineral occurs only massive, the true nature of the species is doubtful.

Analyses: 1, 2, Turner (Edinb. Trans., xi.); 3, Fuchs (Schw. J., lxii. 255); 4, Rammelsberg (Handw., ii. 78); 5, K. List (J. pr. Ch., lxxxiv. 60); 6, Scheffler (Arch. d. Pharm., xxxv. 260); 7–9, Schmid (Pogg., cxxvi. 151):

13. Schneeberg	80·27	14·10	——	4·35	——	[0·23], $\dot{Ca}$ 1·05=100 Schultz.

Pyr., etc.—In the closed tube most varieties yield water, and all lose oxygen on ignition; with the fluxes reacts for manganese. Soluble in muriatic acid, with evolution of chlorine.

Obs.—This is a common ore of manganese. It is frequently in alternating layers with pyrolusite. It occurs in botryoidal and stalactitic shapes, in Devonshire and Cornwall; at Ilefeld in the Harz; also at Johanngeorgenstadt, Schneeberg, Ilmenau, Siegen, etc.; at Elgersburg and Oehrenstock, Thuringia, and Nadabula, Hungary.

It forms mammillary masses at Chittenden, Irasburg, and Brandon, Vt.

Named from ψιλός, *smooth* or *naked*, and μέλας, *black*.

218. WAD. (A) BOG MANGANESE. Magnesia friabilis terriformis *Cronst.*, Min., 105, 1758 Earthy Ochre of Mang., Black Wad pt., *Kirwan*, Min., 1784, 1796. The manganese ores here included occur in amorphous and reniform masses, either earthy or compact, and sometimes incrusting or as stains. They are mixtures of different oxyds, and cannot be considered chemical compounds or distinct mineral species.

H.=0·5—6. G.=3—4·26; often loosely aggregated, and feeling very light to the hands. Color dull black, bluish or brownish-black.

Comp., Var.—Rammelsberg considers them related essentially to psilomelane under the formula $\dot{R}\,\ddot{\bar{M}}n+\dot{H}$ (or $2\,\dot{H}$), but mixed with other ingredients.

Varieties: (A) Manganesian; (B) Cobaltiferous; (C) Cupriferous.

A. BOG MANGANESE. Consists mainly of oxyd of manganese and water, with some oxyd of iron, and often silica, alumina, baryta. The Derbyshire wad sometimes gives the angle of barite, 101° 42′, with which mineral it is in part impregnated. The wad of Leadhills is pseudomorphous after calcite. *Groroilite* occurs in roundish masses of a brownish-black color, and reddish-brown streak; with H. sometimes 6—6·5; it is from Groroi in Mayenne, Vicdessos, and Cautern, in France. *Reissacherite* is the ore analyzed by Hornig (anal. 14), which is remarkable for the amount of water. Huot's name *ouatite* is from the French spelling of wad. *Wad* is of English origin. The *wad* of the Cumberland miners is graphite, a wrong use of the word, says Mawe in his Mineralogy of Derbyshire.

B. ASBOLITE, or Earthy Cobalt, is wad containing oxyd of cobalt, which sometimes amounts to 32 p. c. Named from ἀσβόλη, *soot* (or *Asbolan* from ἀσβολαίνω, to soil like soot). For anal. 15–17, Rammelsberg writes the formula $(\dot{C}o, \dot{C}u)\,\ddot{M}n^2+4\,\dot{H}$. Breithaupt's *cacochlor* includes the ore from Rengersdorf in Lausitz (anal. 15), having H.=2—2·5, G.=3·15—3·29.

C. LAMPADITE, or Cupreous Manganese. A wad containing 4 to 18 p. c. of oxyd of copper, and often oxyd of cobalt also. It graduates into black copper (Melaconite or Kupferschwärze). G.=3·1—3·2. *Peloconite* is a brownish-black variety, having a liver-brown streak; H.=3; G.=2·509—2·567; from Remolinos in Chili.

Special formulas have been written for several of the following analyses; but these bog minerals are not simple species.

Analyses: 1, Klaproth (Beitr., iii. 311); 2, 3, Turner (Edinb. J. Sci. N. S., ii. 213); 4, 5, Berthier (Ann. Ch. Phys., li. 19); 6, Wackenroder (Kastn. Archiv., xiii. 302, xiv. 257); 7, Scheffler (Arch. d. Pharm., xxxv. 260); 8, Rammelsberg (Pogg., lxii. 157); 9, Igelström (Jahresb., xxv. 342); 10, 11, Beck (Rep. Min. N. Y., 55); 12, Berthier; 13, Bahr (J. pr. Ch., liii. 308, fr. Oefv. Ak. Stockh., 240, 1850); 14, E. Hornig (Jahrb. G. Reichs., vii. 312); 15, Klaproth (Beitr., ii. 308); 16, Döbereiner (Gilb. Ann., lxvii. 333); 17, Rammelsberg (Pogg., liv. 551); 18, Kersten (Schw J., lxvi. 1); 19, Rammelsberg (Pogg., liv. 545); 20, Böttger (ib.):

[a] With oxyd of manganese. [b] With oxyd of nickel.

Pyr., etc.—*Wad* reacts like psilomelane. *Earthy cobalt* gives a blue bead with salt of phosphorus, and when heated in R.F. on charcoal with tin, some specimens yield a red opaque bead (copper). *Cupreous manganese* gives similar reactions, and three varieties give a strong manganese reaction with soda, and evolve chlorine when treated with muriatic acid.

Obs.—The above ores are results of the decomposition of other ores—partly of oxyds, and partly of manganesian carbonates. They occur at the localities above mentioned, and many other places. Wad or bog manganese is abundant in the counties of Columbia and Duchess, N. Y., at Austerlitz, Canaan Centre, and elsewhere, where it occurs as a marsh deposit, and, according to Mather, has proceeded from the alteration of brown spar; also in the south-west part of Martinsburg, Lewis Co., in a swamp. There are large deposits of bog manganese at Blue Hill Bay, Dover, and other places in Maine.

Earthy cobalt occurs with cobalt pyrites at Riechelsdorf in Hesse; Saalfeld in Thuringia; at Nertschinsk in Siberia; at Alderly Edge in Cheshire. An earthy cobalt occurs at Mine la Motte, Missouri, which contains 10 or 11 p. c. of oxyd of nickel, besides oxyd of cobalt and copper, with iron, lead, and sulphur; also near Silver Bluff, South Carolina, affording 24 p. c. of oxyd of cobalt to 76 of oxyd of manganese.

Cupreous manganese is found at Schlackenwald, and at Kamsdorf near Saalfeld; at Lauterberg in the Harz. *Peloconite* is from Remolinos, Chili, where it occurs with chrysocolla, or malachite.

Varvacite. Varvacite, referred to on p. 171 as an altered manganite, approaches a wad in composition. Phillips obtained (Phil. Mag., vi. 281, vii. 284) Mn 68·3, O 31·7, $\dot{\mathrm{H}}$ 5·0; or $\dot{\mathrm{M}}\mathrm{n}$ 81·7, O 13·3, $\dot{\mathrm{H}}$ 5·0. A similar compound from Ilefeld in the Harz (in part pseudomorphous after calcite) afforded Turner $\dot{\mathrm{M}}\mathrm{n}$ 80·79, O 14·23, $\dot{\mathrm{H}}$ 4·98=100, and Duflos (Schw. J., lxiv. 81) $\dot{\mathrm{M}}\mathrm{n}$ 81·40, O 13·47, $\dot{\mathrm{H}}$ 5·13=100.

II. OXYDS OF ELEMENTS OF THE ARSENIC AND SULPHUR GROUPS, SERIES II.

1. ARSENOLITE GROUP. Comp. $R\,O^3$. Isometric.

219. Arsenolite	$As\,O^3$	220. Senarmontite	$Sb\,O^3$

2. VALENTINITE GROUP. Comp. $R\,O^3$. Orthorhombic.

221. Valentinite	$Sb\,O^3$	224. Molybdite	$Mo\,O^3$
222. (?) Bismite	$Bi\,O^3$	225. Tungstite	$W\,O^3$
223. (?) Karelinite	$Bi\,O^3+[\frac{1}{2}Bi\,S]$		

3. KERMESITE GROUP. Comp. $R\,O^3$, with S replacing part of O. Monoclinic.

226. Kermesite	$Sb\,(O,\,S)^3$

4. CERVANTITE GROUP. Comp. $R\,O^3+R\,O^5$.

227. Cervantite	$Sb\,O^3+Sb\,O^5$.

Appendix.—228. Stibiconite $Sb\,O^4+aq$. 229. Volgerite $Sb\,O^5+aq$.

219. ARSENOLITE. Arsenicum nativum farinaceum, A. n. crystallinum, *Wall.*, 224, 1747. A. calciforme *Cronst.*, 207, 1758. A. cubicum, etc., *Linn.*, 1768. White Arsenic *Hill*, 1771. Arsenic blanc natif *Fr.* Naturlicher Arsenikkalk. Arsenikblüthe *Karst.*, Tab., 79, 1800. Arsenic oxidé *H.* Acide arsenieux *Fr.* Oxyd of Arsenic, Arsenous acid. Arsenige Säure *Germ.* Arsenit *Haid.*, Handb., 487, 1845. Arsenolite *Dana*, Min., 139, 1854.

Isometric. In octahedrons (f. 2). Usually in minute capillary crystals, stellarly aggregated, or crusts investing other substances. Also botryoidal, stalactitic; earthy.

H.=1·5. G.=3·698, Roget & Dumas. Lustre vitreous or silky. Color white, occasionally with a yellowish or reddish tinge. Streak white, pale yellowish. Transparent—opaque. Taste astringent, sweetish.

Comp.—$\bar{\bar{A}}s$=Oxygen 24·24, arsenic 75·76=100.

Pyr., etc.—Sublimes in the closed tube, condensing above in minute octahedrons. B.B. on charcoal volatilizes in white fumes, giving a white coating and an alliaceous odor. Slightly soluble in hot water.

Obs.—Accompanies ores of silver, lead, arsenical iron, cobalt, nickel, antimony, etc., as a result of the decomposition of arsenical ores. Occurs at Andreasberg in the Harz; at Wheal Sparnon in Cornwall; Joachimsthal in Bohemia; Kapnik in Hungary; tho old mines of Biber in Hanau; the Ophir mine, Nevada; the Armagosa mine, Great Basin, Cal.

Arsenolite has been observed as a furnace product in *orthorhombic* crystals, probably isomorphous with valentinite. $\bar{\bar{A}}s$ and $\bar{\bar{S}}b$ are known to be isodimorphous. The prismatic form is obtained from sublimation at a temperature above 200° C., and the isometric at one much lower.

As the name *arsenite* is used in chemistry for compounds of arsenous acid, the author in 1854 changed it to *arsenolite*.

Alt.—Native arsenic is often covered by a blackish crust or powder, which has been considered a suboxyd ($\dot{\mathrm{A}}\mathrm{s}$); but according to Suckow, it is a mixture of metallic arsenic and arsenous acid.

220. SENARMONTITE. Antimoine oxydé octaédrique *H. de Senarmont*, Ann. Ch. Phys., III. xxxi. 504, 1851. Senarmontite *Dana*, Am. J. Sci., II. xii. 209, 1851.

Isometric; in octahedrons (f. 2). Cleavage: octahedral, in traces. Also granular massive; in crusts.

H.=2–2·5. G.=5·22—5·3. Lustre resinous, inclining to subadamantine. Transparent—translucent. Colorless or grayish. Streak white.

Comp.—$\overline{\mathrm{S}}\mathrm{b}$ (like valentinite)=Oxygen 16·44, antimony 83·56=100, with sometimes 1 p. c. of lead and 1 to 3 p. c. of grayish clay, Rivot (l. c.).

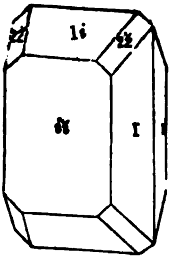
Pyr., etc.—In the closed tube fuses and partially sublimes. B.B. on charcoal fuses easily, and gives a white coating; this treated in R.F. colors the outer flame greenish-blue. Soluble in muriatic acid.

Obs.—A result of the decomposition of stibnite and other ores of antimony. First found in the district of Haraclas in Algeria; occurs also at Perneck near Malaczka in Hungary; Endellion in Cornwall; the antimony mine of S. Ham, Canada. The octahedrons from Algeria are sometimes nearly ½ in. in diameter.

Named after H. de Senarmont, who first described the species.

221. VALENTINITE. Chaux d'antimoine native (fr. Chalanches) *Monges*, J. de Phys., xxiii. 66, 1783; (fr. Przibram) *Rössler*, Crell's Ann., 1787, i. 334. Antimonium spatosum album *Hacquet*, ib., 1788, i. 523. Weiss-Spiesglaserz *Wern.*, *Hoffm.*, Bergm. J., 385, 398, 1789. Weiss-Spiessglanzerz *Klapr.*, Crell's Ann., 1789, i. 9; *Beitr.*, iii. 183, 1802. Antimoine oxydé *H.*, Tr., iv. 1801. White Antimonial Ore *Kirwan*, i. 251, 1796. White Antimony, Oxyd of Antimony. Antimonblüthe *v. Leonh.*, Handb., 160, 1821. Exitèle *Beud.*, Min., 615, 1832. Exitelite *Chapman*, Min., 39, 1843. Valentinit *Haid.*, Handb., 506, 1845.

179



Orthorhombic. $I\wedge I$=136° 58′; $O\wedge 1\text{-}\bar{i}$=105° 35′; $a:b:c$=3·5868 : 1 : 2·5365. Observed planes: I, $i\text{-}\breve{i}$, $\frac{1}{3}\text{-}\breve{i}$, $1\text{-}\bar{i}$, $4\text{-}\breve{i}$,, $2\text{-}\breve{2}$. $1\text{-}\breve{i}\wedge 1\text{-}\breve{i}$, adj.,=70° 32′, $\frac{1}{3}\text{-}\breve{i}\wedge\frac{1}{3}\text{-}\breve{i}$=129° 32′, $I\wedge i\text{-}\breve{i}$= 111° 31′. Often in rectangular plates with the lateral edges bevelled, and in acicular rhombic prisms. Cleavage: I, highly perfect, easily obtained, Twins: composition-plane, $i\text{-}\breve{i}$, producing an aggregation of thin plates. Also massive; structure lamellar, columnar, granular.

H. = 2·5—3. G. = 5·566, crystals from Bräunsdorf. Lustre adamantine, $i\text{-}\breve{i}$ often pearly; shining. Color snow-white, occasionally peach-blossom red, and ash-gray to brownish. Streak white. Translucent—subtransparent.

Comp.—$\overline{\mathrm{S}}\mathrm{b}$=Oxygen 16·44, antimony 83·56=100. **Analysis:** 1, Vauquelin (Haüy's Min., iv 274); 2, Suckow (Jahresb., 1849, 733):

1. Allemont	Oxyd of antimony 86	Ibid. with $\overline{\mathrm{F}}\mathrm{e}$ 3	Silica 8=97.
2. Wolfach	" " 91·7	" $\overline{\mathrm{F}}\mathrm{e}$ 1·2	" 0·8, Sb 6·3=100.

Monges, who makes the first mention of this mineral from a discovery of the acicular variety at Allemont, correctly regarded it as native oxyd of antimony, as afterward confirmed by Vauquelin, and by Rössler (l. c.) for the Bohemian variety. Prof. Hacquet and Klaproth announced in 1788, 1789, the probable presence in the latter of muriatic acid; but in 1802 Klaproth pronounced this also pure oxyd of antimony.

Pyr., etc.—Same as for senarmontite.

Obs.—Occurs with other antimonial ores, and results from their alteration. Found at Przibram in Bohemia, in veins traversing metamorphic rocks; at Felsobanya in Hungary, with stibnite and arsenopyrite; Malaczka in Hungary; Bräunsdorf near Freiberg in Saxony: Allemont in Dauphiny. Also at the antimony mine of South Ham, Canada East.

Antimonophyllite of Breithaupt, of unknown locality, occurring in thin angular six-sided prisms, is probably valentinite.

The *prismatic* form of $\bar{\dddot{\text{S}}}\text{b}$ is obtained from solutions at a temperature above 100°C.

Named after Basil Valentine, an alchemist of the 15th century, who discovered the properties of antimony.

222. BISMITE. Oxyd of Bismuth, Bismuth Ochre. Wismuthocker *Germ.* Bismuth oxydé *Fr.* Bismite *Dana.*

Crystalline form not observed. Occurs massive and disseminated, pulverulent, earthy; also passing into foliated.

G.=4·3611, Büsson. Lustre adamantine—dull, earthy. Color greenish-yellow, straw-yellow, grayish-white. Fracture conchoidal—earthy.

Comp.—$\bar{\dddot{\text{B}}}\text{i}$=Oxygen 10·35, bismuth 89·65=100, along with some iron and other impurities. Analysis by Lampadius (Handb. ch. Anal., 286):

Oxyd of bismuth 86·4, oxyd of iron 5·1, carbonic acid 4·1, water 3·4=99.

Suckow obtained for another from Fichtelgebirge, derived from the decomposition of aikinite (Die Verwitt. im Min., 14), $\bar{\dddot{\text{B}}}\text{i}$ 96·5, $\bar{\dddot{\text{A}}}\text{s}$ 1·5, $\bar{\dddot{\text{F}}}\text{e}^2\,\dot{\text{H}}^3$ 2·0=100.

Pyr., etc.—In the closed tube most specimens give off water. B.B. on charcoal fuses, and is easily reduced to metallic bismuth, which in O.F. gives a yellow coating of oxyd. Soluble in nitric acid.

Obs.—Occurs pulverulent at Schneeberg in Saxony, at Joachimsthal in Bohemia; with native gold at Beresof in Siberia; in Cornwall, in St. Roach, and near Lostwithiel.

Dr. Jackson reports an oxyd of bismuth not carbonated, as occurring with the tetradymite of Virginia.

See further, BISMUTITE, p 716.

223. KARELINITE. Karelinit *Hermann*, J. pr. Ch., lxxv. 448, 1858.

Massive. Structure crystalline. Cleavage in one direction rather distinct.

H.=2. G.=6·60, Herm. Lustre strongly metallic within. Color lead-gray.

Comp.—$\bar{\dddot{\text{B}}}\text{i}$ with Bi S. Analysis: Hermann (l. c.):

O [5·21] S 3·53 Bi 91·26=100

Pyr., etc.—In tube gives sulphurous acid but no sulphur, yielding a gray slag with globules of bismuth.

Obs.—From the Savodinsk mine in the Altai, along with hessite (telluric silver). The mineral is not homogeneous, containing along with the metallic substance a gray, earthy mass of bismutite. By treating the powdered mass with muriatic acid, a metallic powder remains, which, examined with a lens, and washed, proves to be entirely free from any native bismuth, and is the mineral karelinite.

Named after Mr. Karelin, the discoverer.

224. MOLYBDITE. Molybdena or Molybdic Ochre, Molybdic Acid. Molybdänocker *Germ.* Molybdine *Greg & Lettsom,* This Min., 144, 1854. Brit. Min., 348, 1858. Molybdite *Breith.,* B. H. Ztg., xvii. 125, 1858.

Orthorhombic. $I \wedge I$=136° 48′, and isomorphous with valentinite, Breith (fr. artif. cryst.). In capillary crystallizations tufted and radiated; also subfibrous massive; and as an earthy powder or incrustation.

H.=1—2. G.=4·49—4·50, Weisbach. Lustre of crystals silky to adamantine; earthy. Color straw-yellow, yellowish-white.

Comp.—$\dddot{\mathrm{M}}\mathrm{o}$=Oxygen 34·29, molybdenum 65·71=100.

Pyr., etc.—B.B. on charcoal fuses and coats the charcoal with minute yellowish crystals of molybdic acid near the assay, becoming white near the outer edge of the coating. This coating treated for an instant in R.F. assumes a deep blue color, which changes to dark red on continued heating. With borax gives in O.F. a yellow bead while hot, becoming colorless on cooling: in R.F. a saturated bead becomes brown or black and opaque. With salt of phosphorus gives a yellowish bead in O.F., becoming green when treated in R.F. and allowed to cool.

Obs.—Occurs with molybdenite, from which it is probably derived, at the foreign localities of that species; at Adun Tschilon in Dauria, and at Pitkäranta on L. Ladoga, in silky tufts of capillary crystals.

In N. Hamp., at Westmoreland, earthy; in Penn., at Chester, Delaware Co.; Georgia, Heard Co., in silky fibrous tufts; in the gold region, a few miles north of Virginia City, Nevada, in subfibrous masses, and tufted crystallizations of a deep yellow color (called *molybdate of iron* by D. D. Owen, in Proc. Ac. Philad., vi. 108, but shown by Genth to be this species mixed with limonite).

Artificial crystals of molybdite afforded A. E. Nordenskiöld the planes O, i-$\bar{i}$, i-$\breve{i}$, i-$\breve{\frac{3}{2}}$, $\frac{2}{3}$-$\bar{i}$, $\frac{1}{2}$-$\bar{i}$, $\frac{1}{3}$-$\bar{i}$, and the following angles: $O\wedge\frac{1}{3}$-$\bar{i}$=157° 7′, $O\wedge\frac{1}{2}$-$\bar{i}$=148° 5′, $O\wedge\frac{2}{3}$-$\bar{i}$=140° 3′, i-$\breve{i}\wedge i$-$\breve{\frac{3}{2}}$=106° 12; and gave $a:b:c$=0·4792 : 1 : 0·3872. Doubling the vertical axis, $a:b:c$=0·9584 : 1 : 0·3872, which is very closely the relation in the corresponding acid of vanadium, which has $a:b:c$=0·9590 : 1 : 0·3832. The above dimensions correspond to $I\wedge I$=137° 40.′

225. TUNGSTITE. Tungstic Ochre *B. Silliman*, Am. J. Sci., iv. 52, 1822. Wolframocker, Scheelsaure *Germ.* Wolframine *Lettsom & Greg*, This Min., 1854, Brit. Min., 349, 1853

Pulverulent and earthy.
Color bright-yellow, or yellowish-green.

Comp.—$\dddot{\mathrm{W}}$, or pure tungstic acid=Oxygen 20·7, tungsten 79·3=100.

Pyr., etc.—B.B. on charcoal becomes black in the inner flame, but infusible. With salt of phosphorus gives in O.F. a colorless or yellowish bead, which treated in R.F. gives a blue glass on cooling. Soluble in alkalies, but not in acids.

Obs.—Occurs with wolfram in Cumberland, and Cornwall, England; at Lane's mine, Monroe, Ct., filling small cavities in other ores of tungsten, or coating them, and has resulted from their decomposition; in Cabarrus Co., N. C.; at St. Leonard, near Limoges, rarely in distinct cubes of a sulphur-yellow color on wolfram and quartz, a fine specimen of which is contained in the cabinet of Mr. Adam of Paris.

Artificial crystals, according to A. E. Nordenskiöld (Pogg., cxiv., 223), are orthorhombic, with $I\wedge I$=110°, and $a:b:c$=0·4026 : 1 : 0·6966; G.=6·302—6·384. These axes approximate to those of molybdite, if for c, $\frac{2}{3}c$ is substituted, and then this axis is made the vertical; the axes becoming 0·4644 : 1 : 0·4026.

The name *Wolframine* is changed to *Tungstite* in order to get rid of the chemical termination *ine*. *Wolframite* has been used for another species.

226. KERMESITE. Röd Spitsglasmalm, Antimonium Sul. et Ars. mineralisatum, Minera Ant. colorata, *Wall.*, 239, 1747 (fr. Bräunsdorf), *Cronst.*, 203, 1758. Antimonium plumosum *v. Born*, Lithoph., i. 137, 1772. Mine d'antimoine en plumes, ib. granuleuse,=Kermes mineral natif, *Sage*, Min., ii. 251, 1779, *de Lisle*, Crist., iii. 56, 60, 1783. Roth-Spiesglaserz *Wern.*, 1789. Rothspiessglanzerz *Emmerling*, Min., 1793; *Klapr.*, Beitr., iii. 132, 1802 (with anal., making it an oxysulphid). Antimoine oxydé sulfuré *H.*, Tabl., 1809. Red Antimony. Spiessglanzblende pt. *Hausm.* Handb., 225, 1813. Antimony Blende *Jameson*, Min. iii. 421, 1820. Antimonblende *Leonh.*, Handb., 157, 1821. Kermès *Beud.*, Tr., ii. 617, 1832. Kermesite *Chapman*, Min., 61, 1843. Pyrostibit *Glock.*, Syn., 16, 1847. Pyrantimonite *Breith.*

Monoclinic. C=77° 51′; $O\wedge i$-i=102° 9′, $O\wedge 1$-i, plane on acute edge,=115° 36′, $O \wedge \frac{1}{2}\text{-}i$=149° 57′. Cleavage: basal. Usually in tufts of capillary crystals, consisting of elongated, slender, six-sided prisms.

H.=1–1·5. G.=4·5–4·6. Lustre adamantine, inclining to metallic. Color cherry-red. Streak brownish-red. Feebly translucent. Sectile. Thin leaves slightly flexible.

Comp.—$SbO^3 + 2SbS^3$=Antimony 75·3, sulphur 19·8, oxygen 4·9=100. Analyses: H. Rose (Pogg., iii. 453, the sulphur separately determined):

1. Bräunsdorf	Antimony	74·45	Oxygen	5·29	Sulphur	20·49
2. "	"	75·66	"	4·27	"	20·49

Pyr., etc.—In the closed tube blackens, fuses, and at first gives a white sublimate of oxyd of antimony; with strong heat gives a black or dark-red sublimate. In the open tube and on charcoal reacts like stibnite.

Obs.—Results from the change of gray antimony. Occurs in veins in quartz, accompanying stibnite and valentinite, at Malaczka near Posing in Hungary; at Bräunsdorf near Freiberg in Saxony; at Allemont in Dauphiny; at New Cumnock in Ayrshire, Scotland; at South Ham, Canada East.

The *tinder ore* (*Zunderers*) has been shown to be wholly distinct from red antimony.

Artif.—This species is the compound long known in chemistry under the name of *kermes*.

227. CERVANTITE. Spiesglanzokker pt. *Karst.*, Mus. Lesk., i. 534, 1789, Tab., 54, 78, 1800. Antimony Ochre pt. Antimonocher pt. *Germ.* Gelbantimonerz (from Hungary) *Breith.*, Char., 98, 1823, 224, 1832. Acide antimonieux *Dufr.*, Min., ii. 654, 1845. Antimonous Acid, Antimonoso-antimonic Oxyd. Cervantite *Dana*, Min., 1854.

Orthorhombic. In acicular crystallizations. Also massive; as a crust, or a powder.

H.=4–5. G.=4·084. Lustre greasy or pearly, bright or earthy. Color isabella-yellow, sulphur-yellow, or nearly white, sometimes reddish-white. Streak yellowish-white to white.

Comp.—SbO^4, or $SbO^3 + SbO^5$=Oxygen 20·8, antimony 79·2=100. Analyses: 1, Dufrenoy (l. c.); 2, Bechi (Am. J. Sci., II. xiv. 61); 3, Phipson (C. R., lii. 752):

	O	Sb	$\dot{C}a\ \ddot{C}$	$\bar{F}e$
1. Cervantes	16·85	67·50	11·45	1·50, gangue 2·70=99·80 Dufrenoy.
2. Pereta, Tusc.	19·47	78·83	——	1·25, gangue 0·75=100·30 Bechi.
3. Borneo	65·00		——	$\bar{F}e$, $\ddot{\bar{A}}l$ 10·00, $\dddot{S}i$, etc., 21·25, $\dot{H}$ 3·75=100 Phipson.

The compound $SbO^3 + SbO^5$, free of water, is formed by different methods in chemistry, as by the roasting of stibnite, or of valentinite, etc.; and when pure it is white.

Pyr., etc.—B.B. infusible and unaltered; on charcoal easily reduced. Soluble in muriatic acid.

Obs.—Occurs at various mines of stibnite, and results from the alteration of this and other antimonial ores. Found at Cervantes in Galicia, Spain; Chazelles in Auvergne; Felsobanya, Kremnitz, and elsewhere in Hungary; Pereta in Tuscany (anal. 2); near St. Minvers, at Wheal Lea, at Wheal Kine, and at Endellion, in Cornwall; in Ayrshire, Scotland, at Hare Hill; in Borneo, in rhombic prisms half an inch long, terminating in two planes, and also massive; at the Carmen mine at Zacualpan in Mexico; at South Ham, Canada East; in California, Tulare Co., at Pass of San Amedio, with stibnite.

Phipson makes the Borneo mineral a hydrate, with the formula $SbO^4 + \dot{H}$. But, as Brush observes (Am. J. Sci., II. xxxiv. 207), the oxyd of iron and silicate of alumina present as impurities in a pale yellowish or reddish-white mineral, would have had, in combination, at least 3 p. c. of the water, if in the states of limonite and kaolin. Moreover, the fact which Phipson states, that the mineral is unaltered when heated, is further evidence that it is not a hydrate.

228. STIBICONITE. Antimony Ochre pt. (Syn. under Cervantite). Stibiconise *Beud.*, Tr, ii 616, 1832. Stiblith *Blum & Delffs*, J. pr. Ch., xl. 318. Stibiconite *Brush*, Am. J. Sci., II. xxxiv. 207, 1862.

Massive, compact. Also as a powder and in crusts.
H.=4—5·5. G.=5·28, B. & D. Lustre pearly to earthy. Color pale yellow to yellowish-white, reddish-white.

Formula given, $Sb\,O^4+\dot{H}$=Oxygen 19·6, antimony 74·9, water 5·5=100.
Analysis: Blum & Delffs (l. c.):

	O	Sb	As	$\dot{H}$
Goldkronach	19·54	75·88	*tr.*	4·68=100 B. & D.

Beudant states that stibiconite yields water, and he makes it in his formula antimonious acid with $x\dot{H}$. Blum & Delffs say that the water they obtained was probably mechanically mixed, but no reason for this conclusion is given. Volger states (Entw. Min., 72, 1854) that the stibiconite is a mixture of the following hydrous species with cervantite and valentinite. The compound $Sb\,O^4+\dot{H}$ has been formed artificially; but its existence in nature appears still to be doubtful. Beudant mentions no particular locality. Blum & Delffs enumerate others besides Goldkronach in Bavaria, but evidently aim to include all localities of antimony ochre.

Partzite of A. Arents (Am. J. Sci., II. xliii. 362) appears to be a hydrous oxyd of antimony mixed with various metallic oxyds, as pronounced by Blake (ib., xliv. 119). It varies in color from yellowish-green to blackish-green and black; has G.=3·8; H.=3—4; and an even conchoidal fracture.

An analysis afforded Arents $\ddot{S}b$ 47·65, $\dot{C}u$ 32·11, $\dot{A}g$ 6·12, $\dot{P}b$ 2·01, $\dot{F}e$ 2·33, $\dot{H}$ 8·29=98·51. It occurs in the Blind Spring Mts., Mono Co., California, with argentiferous galenite, and antimonial ores of lead and silver, from whose decomposition it has probably proceeded.

Stetefeldtite of E. Riotte (B. H. Ztg., xxvi. 253, July, 1866) appears to be very similar to the partzite. It occurs massive; blackish and brown in color; H.=3·5—4·5; G.=4·12—4·24, with a shining streak.

Stetefeldt found as a mean of two analyses: $Sb\,O^4$ 43·77, S 4·7, Ag 23·74, Cu 12·78, Fe 1·82, $\dot{H}$ 7·9; and thence deduces $Sb\,O^5$ 46·47, S 4·59, Ag 23·23, Cu 2·27, $\dot{F}e$ 2·41, $\dot{C}u$ 13·28, $\dot{H}$ 7·75=10
It comes from South-eastern Nevada, in the Empire district; also in the Philadelphia district

229. VOLGERITE. Antimony Ochre pt. Hydrous Antimonic Acid.

Massive, or as a powder.
Color white.

Comp.—$Sb\,O^5+5\,\dot{H}$=Oxygen 19·3, antimony 58·9, water 21·8=100, Volger (Entwickl. Min., 77). The analysis of Cumenge corresponds to $Sb\,O^5+4\,\dot{H}$.
Analysis: Cumenge (Ann. d. M., IV., xx. 80):

O 17 Sb 62 $\dot{H}$ 15 $\dot{F}e$ 1 gangue 3=98.

$Sb\,O^5+5\,\dot{H}$ is easily obtained artificially. It is tasteless, insoluble in water and acids, and has G.=6·6, Boullay. It gives off its water at a heat below redness, and oxygen at a red heat. There is also a compound $Sb\,O^5+4\,\dot{H}$; but this is much less stable (Watt's Dict. Chem.).

Obs.—The mineral analyzed by Cumenge was from the province of Constantine, Algeria. Volger remarks that this white antimony ochre [illegible] a common result of the alteration of stibnite.

230. **Tellurite.** (Tellurige Säure *Pets*, Pogg., lvii. 478, 1842; Tellurite *Nicol*, Min., 429.) Small yellowish or whitish spherical masses, radiated in structure, and a yellowish, earthy incrustation, occurring with the native tellurium of Facebay and Zalathna; is said to afford the reactions of *tellurous acid*.

230A. **Tantalic Ochre.** A tantalic ochre occurs on crystals of tantalite at Pennikoja in Somero Finland; color brownish, lustre vitreous. *A. E. Nordenskiöld*, Finl. Min., 27, 1855.

III. OXYDS OF THE CARBON-SILICON GROUP, SERIES II.

231. QUARTZ. Κρύσταλλος *Theophr.*, etc. Crystallus (with allusion to its hexagonal form and pyramidal terminations) *Plin.*, xxxvii. 9, 10; Silex *Plin.*, xxxvi. 371. Crystallus, Quartzum candidissimum [auriferous], *Germ.* Quertze, Kiselstein, *Agric.*, 276, etc., 444, 459, 465, 1546, 1529. Quarts, Kisel, *Wall.*, 102, 1747. Quartz, Kiesel, *Germ.*

Rhombohedral, and for the most part hemihedral to the rhombohedron (or tetartohedral to the hexagonal prism). $R \wedge R = 94° 15'$, $O \wedge R = 128° 13'$; $a = 1{\cdot}0999$. Observed planes: (*a*) R, $-R$ (or -1), i, most frequent, as in f. 180–182, R and -1 making up the ordinary pyramidal terminations, and the latter often distinguishable from R in being the smaller planes, and sometimes in having feebler lustre or less smoothness; the pyramid sometimes consisting of R alone (f. 183); (*b*) planes 2-2, very common, but only hemihedrally, as in f. 186, and thus corresponding to the faces of a double three-sided pyramid; (*c*) various rhombohedrons replacing the basal edges of the hexagonal pyramid (as 4 in f. 185, $\frac{5}{2}$, 3, and -7, -1, in f. 191, others in f. 192), 3, 4, being the most common; also the rhombohedron $-\frac{1}{2}$ replacing the edges R/R (f. 191, 193, a rough plane, as usual); also, among other rhombohedrons, $\frac{2}{5}$, $\frac{4}{5}$, $\frac{5}{3}$, 2, 6, 7, 10, and the same in the negative series, besides 50 others; (*d*) various trapezohedral forms, situated obliquely about the angles of the pyramids, like 6-$\frac{6}{5}$ in f. 190, and others in f. 192, 193, the planes *gyroidal* or *plagihedral* in position, and inclining upward toward the right or left, and thus being either *right-handed* as in f. 192, or *left-handed* as in f. 190; and again occurring occasionally on each solid angle (as in f. 190), in which case they are *hemihedral* (12 out of the normal 24); or, as is generally the fact, only on the alternate solid angles (as in f. 192), when they are *tetartohedral*; or, more rarely, right-handed on one solid angle, and left-handed on the next, another kind of hemihedral form; among them, in the zone R : 2-2 : i, or -1 : 2-2 : i, there are *below* 2-2 (f. 192) the forms 3-$\frac{3}{2}$, 4-$\frac{4}{3}$ (o' f. 192), 6-$\frac{6}{5}$ (f. 190, and o''' f. 192), 12-$\frac{12}{11}$, etc., and many others; *above* 2-2, $\frac{3}{2}$-$\frac{3}{2}$, $\frac{4}{3}$-$\frac{4}{3}$, $\frac{6}{5}$-$\frac{6}{5}$, $\frac{8}{7}$-$\frac{8}{7}$, $\frac{9}{8}$-$\frac{9}{8}$ (f. 193), etc.; (*e*) other trapezohedrons bevelling the obtuse edges of the rhombohedron R, as $\frac{1}{5}$-3, $\frac{1}{4}$-3, $\frac{1}{2}$-$\frac{4}{3}$, 1-5, etc.; also (*f*) many trapezohedrons in other positions; the total number of different forms over 175.

$i \wedge R = 141° 47'$	$i \wedge 6\text{-}\frac{6}{5} = 167° 59'$	$R \wedge -1$, ov. i, $= 103° 34'$.
$i \wedge \frac{5}{3} = 154\ 43$	$i \wedge 8\text{-}\frac{8}{7} = 171\ 8$	$R \wedge -1$, adj., $= 133\ 44$.
$i \wedge 2 = 158\ 31$	$i \wedge 13\text{-}\frac{13}{12} = 174\ 39$	$R \wedge i$, ov. 2-2, $= 113\ 8$.
$i \wedge 3 = 165\ 18$	$i \wedge \frac{4}{3}\text{-}\frac{4}{3}$, ov. 2-2, $= 125\ 28$	$R \wedge 2\text{-}2 = 151\ 6$.
$i \wedge 2\text{-}2 = 142\ 2$	$i \wedge \frac{8}{5}\text{-}\frac{8}{5}$, ov. 2-2, $= 118\ 7$	$R \wedge 3 = 155\ 59$.
$i \wedge 3\text{-}\frac{3}{2} = 154$	$i \wedge i = 120$	$R \wedge 4 = 152\ 55$.
$i \wedge 4\text{-}\frac{4}{3} = 161\ 31$	$i \wedge i\text{-}\frac{6}{5} = 171\ 33$	$R \wedge \frac{8}{5}\text{-}\frac{8}{5} = 175\ 1$.

Cleavage: R, -1, and i very indistinct: sometimes effected by plunging a heated crystal in cold water. Crystals either very short, or very much

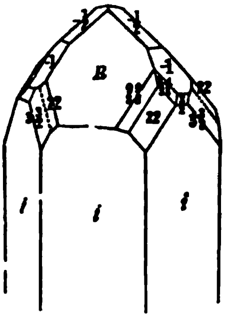
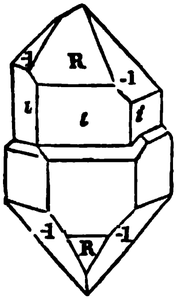
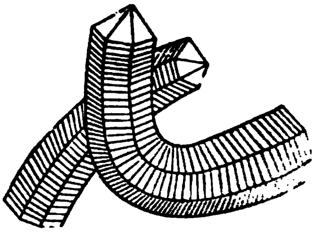
192



193



194

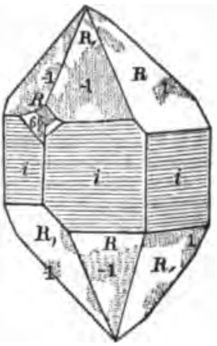


195

elongated, sometimes fine acicular; usually implanted by one extremity of the prism; occasionally twisted or bent (f. 195). Prismatic faces *i* commonly striated horizontally (f. 189, 195, 196), and thus distinguishable, in distorted crystals, from the pyramidal. Crystals often grouped by juxtaposition, not proper twins. Frequently in radiated masses with a surface of pyramids, or in druses having a surface of pyramids or short crystals.

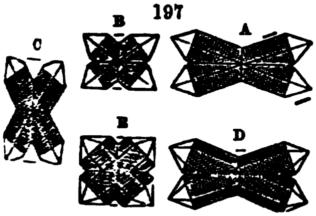
Twins: 1. Composition-face, the basal plane *O*; sometimes (*a*) revolution-twins, or such as correspond to a simple revolution of one-half (made by section parallel to the base), 60° or 180° to the right or left, bringing *R* above into the same vertical line with *R* below, and revolving other planes in a like manner (in f. 192 it would carry half the gyroidal planes to the next edge of the prism, and half the bevelled edge to the place of these planes). Very generally (*b*) *penetration-twins*, the forms not corresponding to a regular revolution, but to an irregular interpenetration of unlike parts of the crystal, making –1 to be distributed in irregular areas over *R*, and so also *R* over –1, with a similar irregular distribution of other planes, as illustrated in f. 196, in which the unshaded parts of the pyramidal faces are *R*, and the shaded parts are –1; crystals of quartz not thus compounded in some part are of very rare occurrence.

196

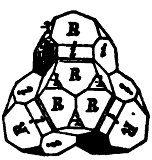


Other twins, mostly geniculating, as in f. 187, and very rarely cruciform (represented cruciform in f. 197, in order to exhibit the divergence of the vertical axes [axes *a*] of the combined crystals, and other relative characteristics): 2. C.-face *R*, or –1, f. 197B; divergence of axes $a = 76° 26'$ (because the angle between axis *R*, and *a* or –1, is 38° 13′); (*a*) simply geniculating, like either half of 197B; (*b*) a three-rayed twin, consisting of a central crystal twinned to three others by each *R* of one extremity, f. 198A, B. 3. Composition between *R* (or –1) and a face of the prism, *i*, f. 197A; divergence of axes $a = 33° 13'$. 4. C.-face $\frac{1}{2}R$, f. 197C; divergence of axes 115° 10′ (angle between axis *a* and face of $\frac{1}{2}R$ being 57° 35′; observed only in simple twins. 5. C.-face 1-2, or plane truncating edge of pyramid between *R* and –1 (a mode of twinning that belongs rather to the true hexagonal system than to the rhombohedral, and showing that the rhombohedral character is often crystallogenically but feebly dominant in the species), illustrated in f. 187 and 197E; divergence of axes $a = 84° 44'$ (because the angle between axis *a* and the pyramidal edge is 42° 17′); observed in geniculating or juxtaposition twins like f. 187, and either half of 195E; there are two kinds, one (*a*) in which faces *R* are correspondent in position in the two parts; (*b*) in which they are not so. 6. Composition between the plane truncating edge of pyramid (or 1-2) and that truncating edge of prism (or *i*-2), f. 197D; angle of divergence 42° 17′.

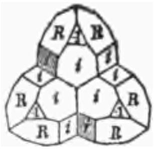
197



198A



198B

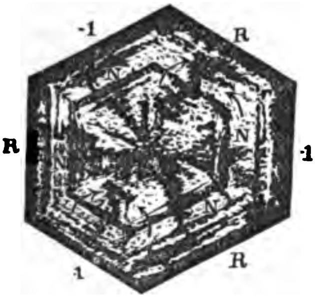


Massive; coarse or fine granular to flint-like or crypto-crystalline. Sometimes mammillary, stalactitic, and in concretionary forms.

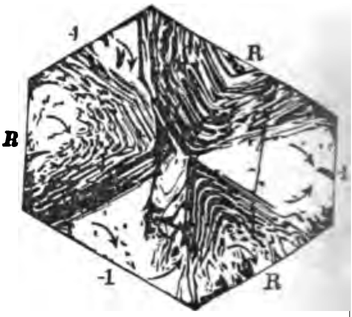
H.=7. G =2·5–2·8; 2·6413–2·6541, Beudant; 2·663, Deville. Lustre vitreous, sometimes inclining to resinous; splendent—nearly dull. Colorless when pure; often various shades of yellow, red, brown, green, blue, black. Streak white, of pure varieties; if impure, often the same as the color, but much paler. Transparent—opaque. Fracture perfect conchoidal—subconchoidal. Tough—brittle—friable. Polarization circular, ther being a colored centre instead of a central cross, and the rings of colo around enlarging as the analyzer is turned to the right in right-handed crystals (f. 192), or left in left-handed (f. 190); and colored spirals are seen which rotate to the right or left, when the incident light and emergen light are polarized, one circularly and the other plane.

For observing the polarization, plates of the crystal are cut at right angles to the axis. I twins the component parts may be both right-handed or both left-handed (as in those of Dauphin and the Swiss Alps); or one may be of one kind and the other of the other. Moreover, successive layers of deposition (made as the crystal went on enlarging, and often exceedingly thin) ar sometimes alternately right and left-handed, showing a constant oscillation of polarity in the cours of its formation; and, when this is the case, and the layers are *regular*, cross-sections, examine by polarized light, exhibit a division, more or less perfect, into sectors of 120°, parallel to th plane *R*, or into sectors of 60°. If the layers are of unequal thickness, there are broad areas o colors without sectors. In f. 199 (by Descloizeaux, from a crystal from the Dept. of the Aude), hal of each sector of 60° is right-handed, and the other half left (as shown by the arrows), and the dar radii are neutral bands produced by the overlapping of layers of the two kinds. In f. 200, from crystal of amethyst (also by Descloizeaux), the alternate white and black lines in each banded sector are due to alternate right and left-handed layers, parallel to *R*. The fact of a structure in layers is easily made manifest by means of fluoric acid, it corroding successive layers unequally. The asteriated internal structure is often apparent in an asteriated arrangement of shades of color o of degrees of transparency. *Biaxial polarization* is sometimes a consequence of the composite structure (as in crystals from Euba, near Schemnitz).

199



200



In crystals, the planes *R* and —1, when not distinguishable by different degrees of lustre, smoothness, or striation, may be by etching with fluoric acid, this process going on unequally i the two directions and producing a difference of surface, besides often developing the layers that were superimposed in the growth of the crystal, alluded to above.

For papers on cryst. of quartz, see Weiss, Mag. Ges. nat. Fr., Berlin, vii. 163; Haidinger, Brewster's J., i. 322, 1824; G. Rose, Ber. Ak. Berlin, 1844, Pogg., lxii. 325. Descloizeaux, Mem. Crist. Jenzsch, Pogg., cxxx. 597, from whom figs. 195A—F are taken. F. Leydolt on the structure of quartz crystals as developed by means of fluoric acid, Ber. Ak. Wien, xv. 59, 1855.

Comp.—Pure silica, or $\dot{Si}$=Oxygen 53·33, silicon 46·67=100. In massive varieties. Often mixed with a little opal-silica. Impure varieties contain oxyd of iron, carbonate of lime, clay, sand and various minerals. Quartz-silica has been supposed to be insoluble in a hot solution of potash, and to be thus distinguishable from opal-silica. But since the investigations of Rammelsberg (Pogg., cxii. 177) it has been questioned whether in a very finely divided state, and especially such as constitutes the compact (cryptocrystalline) chalcedony or flint, it is not more or less soluble. Rammelsberg subjected a number of kinds of quartz to the action of a hot potash solution, and the following are part of his results; under ign. and $\bar{S}$ the *total* loss is given and then, in brackets, the part from drying over sulphuric acid·

	Loss by ign. and $\ddot{S}$.		Dissolved by potash.	
Vitreous massive quartz, Querbach	0·27		5 — 7·75	p. c
Gray hornstone, Schneeberg	2·35	[0·45]	12·82—15	"

Flint, G. 2·62, 2·63	1·40	[0·20]	20·2 —73·4	"

From the high specific gravity of kinds affording a large percentage of soluble silica, it appears that the soluble silica is not all amorphous or opal-silica. Jenzsch has announced (Pogg., cxxvi. 497) that there is a second modification of amorphous silica, distinct from opal, and hitherto unrecognized (see under OPAL), having G.=2·6, like quartz. This suggests an explanation of the above. But the hyalite variety of opal, having G.=2·185, gave Rammelsberg 9·6 to 19·9 p. c. of *insoluble* silica. To explain this fact by the same method still another modification of silica would be required—an insoluble kind, having the low specific gravity of opal.

Pyr., etc.—B.B. alone unaltered. With soda dissolves with effervescence; unacted upon by salt of phosphorus. Soluble only in fluohydric acid.

Var.—1. Crystallized (phenocrystalline), vitreous in lustre. 2. Flint-like massive, or cryptocrystalline. The first division includes all ordinary vitreous quartz, whether having crystalline faces or not. The varieties under the second are in general acted upon somewhat more by attrition, and by chemical agents, as fluoric acid, than those of the first. In all kinds made up of layers, as agate, successive layers are unequally eroded.

A. PHENOCRYSTALLINE OR VITREOUS VARIETIES.

1. *Ordinary Crystallized; Rock Crystal.* Colorless quartz, or nearly so, whether in distinct crystals or not. (*a*) Regular crystals, or limpid quartz; (*b*) right-handed crystals; (*c*) left-handed; (*d*) cavernous crystals, having deep cavities parallel to the faces—occasioned by the interference of impurities during their formation; (*e*) cap-quartz, made up of separable layers or caps, due to the deposit of a little clayey material at intervals in the progress of the crystal; (*f*) drusy quartz, a crust of small or minute quartz crystals; (*g*) radiated quartz, often separable into radiated parts having pyramidal terminations; (*h*) fibrous, rarely delicately so, as a kind from Orange river, near Cape of Good Hope.

2. *Asteriated; Star-quartz* (Stern-quartz *Germ.*). Containing within the crystal whitish or colored radiations along the diametral planes. Part if not all asteriated quartz is asteriated in polarization, as above described.

3. *Amethystine; Amethyst* (Ἀμέθυστον *Theophr.*, etc.). Clear purple, or bluish-violet. The color is supposed to be due to manganese. But Heintz obtained in an analysis of a Brazilian specimen, besides silica, 0·0187 oxyd of iron, 0·6236 lime, 0·0133 magnesia, and 0·0418 soda; and he considers the color owing to a compound of iron and soda. The structure is composite, as illustrated in f. 199, 200, and the shade of violet is usually deepest parallel to the planes *R*.

4. *Rose.* Rose-red or pink, but becoming paler on exposure. Common massive, and then usually much cracked. Lustre sometimes a little greasy. Fuchs states that the color is due to titanic acid; he found 1 to 1½ p. c. in specimens from Rabenstein, near Bodenmais. It may come in part from manganese.

5. *Yellow; False Topaz.* Yellow and pellucid, or nearly so; resembling somewhat yellow topaz, but very different in crystallization and in absence of cleavage.

6. *Smoky, Cairngorm Stone* (Mormorion *Plin.*, xxxvii. 63). Smoky-yellow to smoky-brown, and often transparent; but varying to brownish-black, and then nearly opaque in thick crystals. The color is probably due to titanic acid, as crystals containing rutile are usually smoky. Called *cairngorms* from the locality at Cairngorum, S.W. of Banff, in Scotland.

7. *Milky.* Milk-white and nearly opaque. Lustre often greasy, and then called *greasy* quartz.

8. *Siderite,* or *Sapphire-quartz.* Of indigo or Berlin-blue color; a variety occurring in an impure limestone at Golling in Saltzburg.

9. *Sagenitic.* Containing within acicular crystals of other minerals. These acicular crystals are most commonly (*a*) *rutile*, the mineral called from such specimens *sagenite* (fr. σαγηνη, *a 'net'*) by de Saussure (see under RUTILE). They may also be (*b*) black tourmaline; (*c*) göthite; (*d*) stibnite; (*e*) asbestus; (*f*) actinolite; (*g*) hornblende; (*h*) epidote.

10. *Cat's Eye* (Katzenauge *Germ.*, Œil de Chat *Fr.*). Exhibiting opalescence, but without prismatic colors, especially when cut *en cabochon*, an effect due to fibres of asbestus.

11. *Aventurine.* Spangled with scales of mica or other mineral.

12. *Impure from the presence of distinct minerals* distributed densely through the mass. The more common kinds are those in which the impurities are: (*a*) *ferruginous*, either red or yellow oxyd of iron; (*b*) *chloritic*, some kind of chlorite; (*c*) *actinolitic*; (*d*) *micaceous*; (*e*) *arenaceous*, or sand.

Quartz crystals also occur penetrated by various minerals, as topaz, corundum, chrysoberyl, garnet, different species of the hornblende and pyroxene groups, kyanite, zeolites, calcite and other carbonates, rutile, stibnite, hematite, göthite, magnetite, fluorite, gold, silver, anthracite, etc. As quartz has been crystallized through the aid of hot waters or of steam in all ages down to the present, and is the most common ingredient of rocks, there is good reason why it should be found thus the enveloper of other crystals.

13. *Containing liquids in cavities.* These liquids are seen to move with the change of position of the crystal, provided an air-bubble be present in the cavity; they may be detected also by the refraction of light. The liquid is either water (pure, or a mineral solution), or some petroleum-like or other compound. (See p. 761.)

B. CRYPTOCRYSTALLINE VARIETIES.

1. *Chalcedony* (Murrhina *Plin.*, xxxvii. 7. Ἴασπις pt. *Theophr.* Iaspis pt. *Plin.*, xxxvii. 37 Murrhina, *Germ.* Chalcedonius, *Agric.*, 466, 1546, Chalcedon, Achates vix pellucida, nebulosa colore griseo mixta, *Wall.*, 83, 1747. Calcedoine *Fr.*). Having the lustre nearly of wax, and either transparent or translucent. Color white, grayish, pale-brown to dark-brown, black; tendon-color common; sometimes delicate blue. Also of other shades, and then having other names.

Often mammillary, botryoidal, stalactitic, and occurring lining or filling cavities in rocks. It is true quartz, with some disseminated opal-quartz. A gray chalcedony from Hungary afforded Redtenbacher (Ramm. Min. Ch., 1007) $\ddot{\mathrm{S}}\mathrm{i}$ 98·87, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·53, $\dot{\mathrm{C}}\mathrm{a}\ddot{\mathrm{C}}$ 0·62=100·02.

2. *Carnelian* (Σάρδιον *Theophr.* Sarda *Plin.*, xxxvii. 23, id.=*Germ.* Carneol, *Agric.*, 468, 1546. Carneol, Agates fere pellucida, colore rubescente, *Wall.*, 82, 1747. Cornaline *Fr.*). A clear red chalcedony, pale to deep in shade; also brownish-red to brown, the latter kind (Sardoine *Fr.*) reddish-brown by transmitted light.

Heintz found that the red color was due to oxyd of iron, obtaining in an analysis $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·050 p.c., $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 0·081, Mg 0·028, $\dot{\mathrm{K}}$ 0·0043, $\dot{\mathrm{N}}\mathrm{a}$ 0·075. It has been supposed to be of organic origin.

3. *Chrysoprase* (not Chrysoprasus *antiq.*). An apple-green chalcedony, the color due to the presence of oxyd of nickel. Klaproth found in that of Silesia (Beitr., ii. 127) $\ddot{\mathrm{S}}\mathrm{i}$ 96·16, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 0·08, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·08, $\dot{\mathrm{N}}\mathrm{i}$ 1·0, $\dot{\mathrm{C}}\mathrm{a}$ 0·83, $\dot{\mathrm{H}}$ 1·85=100; and Rammelsberg, in the same (Pogg., cxii. 188), $\ddot{\mathrm{S}}\mathrm{i}$ 97 $\dddot{\bar{\mathrm{F}}}\mathrm{e}$, $\dot{\mathrm{N}}\mathrm{i}$ 0·41, $\dot{\mathrm{C}}\mathrm{a}$, $\dot{\mathrm{M}}\mathrm{g}$ 0·51, $\dot{\mathrm{H}}$ 2·08.

4. *Prase.* Translucent and dull leek-green; so named from πράσον, *a leek.* Always regarded as a stone of little value. The name is also given to crystalline quartz of the same color. "Vilioris est turbæ Prasius." says Pliny.

5. *Plasma* (Iaspis pt. *Plin.*, xxxvii. 37). Rather bright-green to leek-green, and also sometimes nearly emerald-green, and subtranslucent or feebly translucent; sometimes dotted with white.

Heliotrope, or *Blood-stone*, is the same stone essentially, with small spots of red jasper, looking like drops of blood.

The *Iaspis*, or jasper of the ancients, was a semitransparent or translucent stone, and included in Pliny's time all bright-colored chalcedony excepting the carnelian (Sard). He gives special prominence to sky-blue and green, and mentions also a shade of purple (the color of the best, he says), a rose color, the color of the morning sky in autumn, sea-green, terebenthine color (yellow like turpentine, as interpreted by King), smoke-color (his capnias), etc.; but in general there is a tinge of blue, whatever the shade. The green kinds may have been chrysoprase or plasma; or perhaps a variety of jade, a stone known in Europe since the Stone age. The green, with a line running through it (Monogrammos), may have been plasma, or jade, with a narrow seam of white quartz.

Pliny's *Prasius*, spotted with red, was our heliotrope; his *Heliotrope* (xxxvii. 60) was a leek-green stone (prase or plasma) veined with blood-red (jasper); and the jasper was so abundant a part as to give a general red reflection to the whole when it was put in water in the face of the sun, whence the name from ἥλιος, *sun*, and τρέπω, *to turn.*

6. *Agate* (Ἀχάτης [fr. Sicily] *Theophr.* Achates pt. *Plin.*, xxxvii. 54. Onyx pt. *Plin.*, ib., 24). A variegated chalcedony. The colors are either (α) banded; or (β) in clouds; or (γ) due to visible impurities.

α. *Banded.* The bands are delicate parallel lines, of white, tendon-like, wax-like, pale and dark brown, and black colors, and sometimes bluish and other shades. They follow waving or zigzag courses, and are occasionally concentric circular, as in the eye-agate (*Leucophthalmus* Plin., xxxvii. 62, and *Triophthalmus* ib., 71). The fine translucent agates graduated into coarse and opaque kinds. The bands are the edges of layers of deposition, the agate having been formed by a deposit of silica from solutions intermittently supplied, in irregular cavities in rocks, and deriving their concentric waving courses from the irregularities of the walls of the cavity. As the cavity cannot contain enough of the solution to fill it with silica, an open hole has been supposed to be retained on one side to permit the continued supply; but it is more probable that it passes through the outer layers by osmosis, the denser solution outside thus supplying silica as fast as it is deposited within. The colors are due to traces of organic matter, or of oxyds of iron, manganese, or titanium, and largely to differences in rate of deposition. The layers differ in porosity, and therefore in the rate at which they are etched by fluoric acid; and consequently the etching process brings out the different layers, and makes engravings that will print exact pictures of the agate. Owing also to the unequal porosity, agates may be varied in color by artificial means.

A brown banded agate afforded Redtenbacher (Ramm. Min. Ch., 1007) $\ddot{\mathrm{Si}}$ 98·91, $\dddot{\overline{\mathrm{Fe}}}$ 0·72, $\dot{\mathrm{Ca}}\ddot{\mathrm{C}}$ 0·31=99·94.

β. *Irregularly* clouded. The colors various, as in banded agate.

A whitish clouded var. (*a*) is probably the *Leucachates* Plin. (fr. λευκός, *white*); (*b*) a wax-colored, his *Cerachates* (fr. *cera*, *wax*), a name that may have been applied also to ordinary wax-colored chalcedony, as the stone was one in little repute; (*c*) a reddish, his *Sardachates*, or carnelian-agate. The last probably included also banded kinds. *Hemachates* (fr. αἷμα, *blood*) was probably a true light-colored agate, blotched with red jasper, "blushing with spots of blood," as says Solinus (King, p. 207), of which there are very beautiful kinds, and not simple red jasper. *Iaspachates* must have been an agate in which bluish and greenish shades (Iaspis) predominated. These names are given by Pliny without accompanying descriptions.

γ. *Colors due to visible impurities.* (*a*) *Moss-agate*, or *Mocha-stone*, filled with brown moss-like or dendritic forms distributed through the mass. (*b*) *Dendritic Agate*, containing brown or black dendritic markings. These two are the *Dendrachates* Plin. (fr. δένδρον, *a tree*).

There is also δ. *Agatized wood:* wood petrified with clouded agate.

7. *Onyx* (Ὀνύχιον *Theophr*. Onyx pt. [rest agate, stalagmite, q. v.] *Plin.*, xxxvii. 24) Like agate in consisting of layers of different colors, but the layers are in even planes, and the banding therefore straight, and hence its use for cameos, the head being cut in one color, and another serving for the background. The colors of the best are perfectly well defined, and either white and black, or white, brown and black alternate.

8. *Sardonyx* (Plin., xxxvii. 23). Like onyx in structure, but includes layers of carnelian (sard) along with others of white or whitish, and brown, and sometimes black colors.

9. *Agate-Jasper*. An agate consisting of jasper with veinings and cloudings of chalcedony.

10. *Silicious sinter*. Irregularly cellular quartz, formed by deposition from waters containing silica or soluble silicates in solution.

11. *Flint* (Silex pt. *Plin.*, Feuerstein *Germ.*). Somewhat allied to chalcedony, but more opaque, and of dull colors, usually gray, smoky-brown, and brownish-black. The exterior is often whitish, from mixture with lime or chalk, in which it is imbedded. Lustre barely glistening, subvitreous. Breaks with a deeply conchoidal fracture, and a sharp cutting edge. The flint of the chalk formation consists largely of the remains of infusoria (Diatoms), sponges, and other marine productions. The silica of flint, according to Fuchs, is partly soluble silica. See on this point p. 194. There is usually one per cent. or so of alumina and peroxyd of iron, with one or two of water. The coloring matter of the common kinds is mostly carbonaceous matter.

12. *Hornstone* (Silex pt., *Plin.*, Hornstein *Germ.*). Resembles flint, but more brittle, the fracture more splintery. *Chert* is a term often applied to hornstone, and to any impure flinty rock, including the jaspers. A grayish chalcedonic hornstone from Marienbad afforded Kersten $\ddot{\mathrm{Si}}$ 90·30, $\dddot{\overline{\mathrm{Al}}}$ 3·10, $\dddot{\overline{\mathrm{Fe}}}$ 1·73, $\dot{\mathrm{Mg}}$ 1·28, $\dot{\mathrm{Cu}}$ 0·94, $\dot{\mathrm{Na}}$ and $\dot{\mathrm{K}}$ 0·70, $\dot{\mathrm{H}}$ 1·95 (Jahrb. Min., 1845, 656).

13. *Basanite*, *Lydian Stone*, or *Touchstone* (Lapis Lydius *Plin.*, xxxiii. 43, ? Basanites *id.*, xxxvi. 11). A velvet-black siliceous stone or flinty jasper, used on account of its hardness and black color for trying the purity of the precious metals. The color left on the stone after rubbing the metal across it indicates to the experienced eye the amount of alloy. It is not splintery like hornstone. It passes into a compact, fissile, siliceous, or flinty rock, of grayish and other colors, called siliceous slate, and also *Phthanyte;* and then resembles ordinary jasper of grayish and other shades, especially the banded jaspers.

14. *Jasper*. Impure opaque colored quartz. (*a*) *Red* (Hæmatitis *Plin.*, xxxvii. c. 60, not his Hæmatites), sesquioxyd of iron being the coloring matter. (*b*) *Brownish*, or *ochre yellow*, colored by *hydrous* sesquioxyd of iron, and becoming red when so heated as to drive off the water. (*c*) Dark green and brownish-green. (*d*) Grayish-blue. (*e*) Blackish or brownish-black. (*f*) *Striped* or *riband jasper* (Bandjaspis *Germ.*), having the colors in broad stripes. (*g*) *Egyptian jasper*, in nodules which are zoned in brown and yellowish colors.

Porcelain jasper is nothing but baked clay, and differs from true jasper in being B.B. fusible on the edges. *Red porphyry*, or its base, resembles jasper, but is also fusible on the edges, being usually an impure feldspar.

C. Besides the above there are also:—

1. *Granular Quartz*, or *Quartz-rock*. A rock consisting of quartz grains very firmly compacted, the grains often hardly distinct. 2. *Quartzose Sandstone*. 3. *Quartz-conglomerate*. A rock made of pebbles of quartz with sand. The pebbles sometimes are jasper and chalcedony, and make a beautiful stone when polished. 4. *Itacolumite*, or *Flexible Sandstone*. A friable sand-rock, cou

sisting mainly of quartz sand, but containing a little talc, and possessing a degree of flexibility when in thin laminæ. 5. *Buhrstone.* A cellular, flinty rock, having the nature in part of coarse chalcedony.

6. *Pseudomorphous Quartz.* Quartz appears also under the forms of many of the mineral species, which it has taken through either the alteration or replacement of crystals of those species. The most common quartz pseudomorphs are those of calcite, barite, fluorite, and siderite. (*a*) *Tabular quartz* consists of intersecting plates of quartz, and is probably a result of the quartz being deposited among intersecting plates of other minerals, as barite. (*b*) *Haytorite* of C. Tripe (Phil. Mag., i. 40, 1827) is a pseudomorph after datholite. (*c*) *Beckite* Duf. is a pseudomorph after coral, chalcedonic in character, from Devonshire, England; it contains some of the carbonate of lime of the original coral (Church, Phil. Mag., IV. xxiii. 95). (*d*) *Babel-quartz* is quartz which has impressions of cubes of fluor, arising from its having been deposited over the crystals. (*e*) *Silicified shells* are proper pseudomorphs in quartz; they occur through many rock strata, including limestones. (*f*) *Silicified wood* is quartz pseudomorph after wood. The texture of the original wood is usually well retained, it having been formed by the deposit of silica from its solution in the cells of the wood, and finally taking the place of the walls of the cells as the wood itself disappeared.

Pyr., etc.—B.B. unaltered; with borax dissolves slowly to a clear glass; with soda dissolves with effervescence; unacted upon by salt of phosphorus. Insoluble in muriatic acid, and only slightly acted upon by solutions of fixed caustic alkalies. When fused and cooled it becomes opal-silica, having G.=2·2.

Obs.—Quartz occurs as one of the essential constituents of granite, syenite, gneiss, mica schist, and many related rocks; as the principal constituent of quartz-rock and many sandstones; as an unessential ingredient in some trachyte, porphyry, etc.; as the vein-stone in various rocks, and for a large part of mineral veins; as a foreign mineral in the cavities of trap, basalt, and related rocks, some limestones, etc., making geodes of crystals, or of chalcedony, agate, carnelian, etc.; as imbedded nodules or masses in various limestones, constituting the flint of the chalk formation, the hornstone of other limestones—these nodules sometimes becoming continuous layers; as masses of jasper occasionally in limestone. It is the principal material of the pebbles of gravel beds, and of the sands of the sea-shore and sand beds everywhere. It is reported by G. Rose as occurring in the meteorite of Xiquipulco (Pogg., cxiii. 184).

Silica also occurs in solution (but mostly as a soluble alkaline silicate) in heated natural waters, as those of the Geysers of Iceland, New Zealand, and California, and very sparingly in many cold mineral waters.

Switzerland, Dauphiny, Piedmont, the Carrara quarries, and numerous other foreign localities, afford fine specimens of rock crystal. The most beautiful amethysts are brought from India, Ceylon, and Persia, where they occur in geodes, and as pebbles; inferior specimens occur in Transylvania, in large crystalline groups; in the vicinity of Cork, and on the island of May, Ireland. The *false topaz* is met with in Brazil. *Rose quartz* occurs in a vein of manganese, traversing the granite of Rabenstein, near Zwiesel in Bavaria. *Prase* is found in the iron mines of Breitenbrunn, near Schwartzemberg in Saxony; and in Brittany, near Nantes and Rennes. The amygdaloids of Iceland and the Faroe Islands, afford magnificent specimens of *chalcedony;* also Hüttenberg and Loben in Carinthia, etc. A smalt-blue variety, in cubical crystals (pseudomorphs of fluorite), occurs at Treszytan, in Transylvania. The finest *carnelians* and *agates* are found in Arabia, India, Brazil, Surinam, Oberstein, and Saxony. Scotland affords smaller but handsome specimens (Scotch pebbles). *Chrysoprase,* at Kosemütz in Silesia. *Aventurine quartz,* at Cape de Gata in Spain. *Cat's eye,* in Ceylon, the coast of Malabar, and also in the Harz and Bavaria. *Plasma,* in India and China, whence it is usually brought in the form of beads. *Heliotrope,* in Bucharia, Tartary, Siberia, and the island of Rum in the Hebrides. *Float stone,* in the chalk formation of Menil Montant, near Paris, and in some of the Cornish mines. The banks of the Nile afford the Egyptian jasper; the striped jasper is met with in Siberia, Saxony, and Devonshire. A *yellow jasper* is found at Vourla, bay of Smyrna, in a low ridge of limestone, to the right of the watering-place, between the harbor and the high hills back; it is associated with opal, chrysoprase, and hornstone, and these minerals seem to occupy in the limestone the place of hornstone, which is found in various parts of the adjoining country, and also at Napoli di Romania in Greece. The plains of Argos are strewn with pebbles of *red jasper.* A variety of sandstone occurs in thin layers at Villa Rica, Brazil, remarkable for its flexibility; a similar *flexible sandstone* occurs in the North Carolina gold region.

In New York, quartz crystals are abundant in Herkimer Co., at Middleville, Little Falls, Salisbury, and Newport, loose in cavities in the Calciferous sand-rock, or imbedded in loose earth, and sometimes, according to Beck, in powdered anthracite. Fine dodecahedral crystals, at the beds of specular iron in Fowler, Herman, and Edwards, St. Lawrence Co. In Gouverneur, crystals, with tourmaline, etc., in limestone, which have rounded angles as if they had been partially fused. On the banks of Laidlaw lake, Rossie, large implanted crystals. The Sterling ore bed, Antwerp, Jefferson Co., interesting dodecahedral crystals. 4 m. E. of Warwick, crystals presenting the rhombohedral form, in jasper At Palatine, Montgomery Co., crystals, having one end terminated with the usual pyramid, while the other is rounded and smooth. Diamond Rock, near Lansingburgh, an old but poor locality. At Ellenville lead mine, Ulster Co., in elegant groups. At Diamond island and Diamond Point, Lake George, quartz crystals, as in Herkimer Co. In Mass.. crystals with unusual modifications, sparingly at the Charlestown syenite quarry, one of which from the cabinet of Mr. J. E. Teschemacher is represented in f. 193. It has the adjacent planes 2-2 and 3-$\frac{3}{2}$ uneven, and $-\frac{1}{2}$ with a triangular furrow but sharp edges; the rest are lustrous; with the reflective goniometer, reflecting the sun's rays, $R \wedge \frac{8}{3}\text{-}\frac{4}{3} = 175°$. Pelham and Chesterfield, Mass., Paris and Perry, Mo., Benton, N. H., Sharon, Vt., and Meadow Mount, Md., are other localities of quartz crystal. Near Quebec, fig. 191, and other crystals similar, but the inverse. At Chesterfield, Mass., small unpolished *rhombohedrons*, in granite. At Paris, Me., handsome crystals of brown or smoky quartz. In large crystals, often perfect and weighing several pounds, at Minnesota mine, Lake Superior, occasionally enveloped in metallic copper, as if cast around the crystals. Drusy quartz, of brown, apple-green, and other tints, at Newfane, Vt. For other localities, see the catalogue of localities in the latter part of this volume.

Rose quartz, at Albany, and Paris, Me., Acworth, N. H., Williamsburg, Mass., Southbury, Conn., and Port Henry, Essex Co., N. Y.; *smoky quartz*, at Goshen, Mass., Richmond Co., N. Y., etc.; *amethyst*, in trap, at Keweenaw Point, Pic bay, and Gargontwa, on Lake Superior; also in the same rock at Bristol, Rhode Island, and sparingly throughout the trap region of Massachusetts and Connecticut; in Surry, New Hampshire; in Pennsylvania, in East Bradford, Aston, Chester, and Providence (one fine crystal over 7 lbs. in weight), in Chester Co.; very handsome at the Prince vein, Lake Superior, but now hardly obtainable, as the mine is not worked; also very large fine crystals, near Greensboro, N. C. Crystallized green quartz, in talc, at Providence, Delaware Co., Penn.; at Ellenville, N. Y., with chlorite. Chalcedony and agates of moderate beauty, in the same trap region; more abundantly about Lake Superior, the Mississippi, and the streams to the west; at Natural Bridge, Jefferson Co., N. Y.; about the Willamet, Columbia, and other rivers in Oregon; abundant and beautiful on N. W. shore of Lake Superior. Belmont's lead mine, St. Lawrence Co., N. Y., has afforded good chalcedony and chrysoprase, associated with calcite. Red jasper is found on Sugar Loaf Mt., Maine; in pebbles on the banks of the Hudson at Troy; yellow, with chalcedony, at Chester, Mass.; red and yellow, near Murphy's, Calaverus Co., Cal. Heliotrope occupies veins in slate at Bloomingrove, Orange Co., N. Y.

Smoky quartz in large crystals, some over 100 lbs., have been found on Paradise R., Nova Scotia.

Quartz pseudomorphs, after hexagonal and scalenohedral crystals of calcite and cubes of fluorite, at Westhampton, Mass.; after barite, probably, in Rutherford Co., N. C., often filled with water.

Quartz crystals occasionally occur of enormous size. A group in the museum of the university at Naples weighs nearly half a ton. A crystal belonging to Sig. Rafelli, of Milan, measures 3½ ft. in length and 5½ in circumference, and its weight is estimated at 870 lbs; another in Paris is 3 ft. in diameter and weighs 8 cwt. About a century since a drusy cavity was opened at Zinken, which afforded 1,000 cwt. of rock crystal, and at that early period brought $300,000. One crystal weighed 800 lbs. A group from Moose Mountain, New Hampshire, at Dartmouth College, weighs 147½ lbs., and contains 48 crystals; four of them are from 5 to 5½ inches in diameter, ten from 4 to 4½ inches. A crystal from Waterbury, Vt., 2 ft. long and 18 inches through, weighs 175 lbs.

Several varieties of this species have long been employed in jewelry. The *amethyst* has always been esteemed for its beauty. Like most other stones, it is less brilliant by candle-light; it appears to best advantage when surrounded with pearls and set in gold. The color of the amethyst is often irregularly diffused, as is well described by Pliny, "ad viciniam crystalli descendet albicante purpuræ defectu," purple, gradually fading into white. It was called *amethyst*, αμεθυστος, on account of its pretended preservative powers against intoxication, from α, *not*, and μεθυω, *to intoxicate*. This is not, however, the only *amethyst* of the ancients. The violet-colored sapphire, the violet fluorite (scalpturis faciles, Plin., *easily graven*), and some other purple species, were designated by the same name; and it has been supposed that garnet was also included.

Cameos are in general made of onyx, which is well fitted for this kind of miniature sculpture. The most noted of the ancient cameos, is the Mantuan vase at Brunswick. It was cut from a single stone, and has the form of a cream pot, about seven inches high and two and a half broad; on its outside, which is of a brown color, there are white and yellow groups of raised figures, representing Ceres and Triptolemus in search of Proserpine. The Museo Borbonico, at Naples, contains an onyx measuring eleven inches by nine, representing the apotheosis of Augustus, and another exhibiting the apotheosis of Ptolemy on one side and the head of Medusa on the other; both are splendid specimens of the art, and the former is supposed to be the largest in existence.

The carnelian is often rich in color, but is too common to be much esteemed; when first obtained from the rock they are usually gray or grayish-red; they receive their fine colors from an exposure of several weeks to the sun's rays, and a subsequent heating in earthen pots. The colors of agate, when indistinct, may be brought out by boiling in oil, and afterward in sulphuric acid: the latter carbonizes the oil absorbed by the porous layers, and thus increases the contrast of the different colors. Agate is often made into mortars for chemical and pharmaceutical preparations, and, according to Pliny, it was employed for the same purpose by the physicians of his day. Pliny also mentions that "the best cautery for the human body is a ball of crystal acted on by the sun" (xxxvii. 10). He deplores the extravagance of his times, as exhibited in the crystal drinking cups and vases of the wealthy.

Jasper admits of a brilliant polish, and is often formed into vases, boxes, knife-handles, etc. It is also extensively used in the manufacture of Florentine mosaics.

Quartz is distinguished by its *hardness*—scratching glass with facility; *infusibility*—not fusing before the blowpipe; *insolubility*—not attacked by water or the acids; *uncleavability*—one variety being tabular, but proper cleavage never being distinctly observed. To these characteristics the action of soda B.B. may be added.

The word quartz is of German provincial origin. Agate is from the name of the river Achates, in Sicily, whence specimens were brought, as stated by Theophrastus.

Alt.—Pseudomorphs of pyrite, tin ore, stannite, magnetite, hematite, and voltzite, after quartz, have been met with.

232. OPAL. Opalus, Paederos, *Plin.*, xxxvii. 21, 22. Quartz resinite *H.*, Tr., ii. 1801.

Massive, amorphous; sometimes small reniform, stalactitic, or large tuberose. Also earthy.

H.=5·5—6·5. G.=1·9—2·3. Lustre vitreous, frequently subvitreous; often inclining to resinous, and sometimes to pearly. Color white, yellow, red, brown, green, gray, generally pale; dark colors arise from foreign admixtures; sometimes a rich play of colors, or different colors by refracted and reflected light. Streak white. Transparent to nearly opaque.

Comp.—$\ddot{\mathrm{S}}\mathrm{i}$, as for quartz, silica being dimorphous, the opal condition being one of lower degrees of hardness and specific gravity, and, as generally believed, of incapability of crystallization. Water is usually present, but it is regarded as unessential. It varies in amount from 2·75 to 21 p. c.; or, mostly, from 3—9 p. c.$=\ddot{\mathrm{S}}\mathrm{i}+\frac{1}{9}\dot{\mathrm{H}}$ to $\ddot{\mathrm{S}}\mathrm{i}+\frac{1}{3}\dot{\mathrm{H}}$ (or $9\ddot{\mathrm{S}}\mathrm{i}+\dot{\mathrm{H}}$ to $3\ddot{\mathrm{S}}\mathrm{i}+\dot{\mathrm{H}}$). Opal often contains more or less of quartz mixed with it; and most of the analyses are unsatisfactory, because they leave the amount of the latter wholly unconsidered; and since solubility in a hot solution of caustic potash is not a decisive test of opal, as shown by Rammelsberg (Pogg., cxii. 177), no method for its exact determination is known. (See p. 192, under QUARTZ.) Rammelsberg's percentage results are as follows; under the heading ign. & $\bar{\mathrm{S}}$, the sum of the loss by both is given, and in brackets that by drying over sulphuric acid alone:

	G.	G. after ign.	Ign. & $\bar{\mathrm{S}}$.		Insol.
Semiopal, Grochau	2·101	1·878	6·55		7·21
" Vallecas, *brown*	2·216	2·224	11·75	[8·26]	18·5—39·3
" " *white*			4·54	[1·78]	19·2—53·5
Geyserite, Iceland			8·83	[3·41]	4·8 (=$\bar{\mathrm{F}}\mathrm{e}$)
Hyalite, Walsch	2·185		3·28	[0]	9·7—19·9
" " after ign.		1·507			21· —45·9

Moreover, optical characters do not afford decisive distinctions; for Ehrenberg has found (Ber. Ak. Berlin, 65, 1849, Ramm., Pogg., cxii. 191) that *hyalite*, after ignition and before, and *chrysoprase* are alike doubly-refracting; *chalcedony* from Faröe and *semiopal* from Vallecas, doubly-refracting, with spots of singly-refracting; *semiopal* fr. Grochau and *flint*, singly-refracting, with spots of doubly-refracting.

Var.—1. *Precious Opal.* Exhibits a play of delicate colors, or, as Pliny says, presents various refulgent tints in succession, reflecting now one hue and now another. Seldom larger than a hazel nut; a mass in the Vienna museum has the size of a man's fist and weighs 17 oz., but has numerous fissures, and is not wholly free from the matrix.

2. *Fire-opal* (Feueropal, fr. Mexico, *Humboldt*, *Karsten*, Klapr. Beitr., iv. 156, 1807). Hyacinth-red to honey-yellow colors, with fire-like reflections, somewhat irised on turning.

3. *Girasol.* Bluish-white, translucent, with reddish reflections in a bright light.

4. *Common Opal.* In part translucent; (*a*) milk-white to greenish, yellowish, bluish; (*b*) *Resin opal* (Wachsopal, Pechopal, *Germ.*), wax-, honey- to ochre-yellow, with a resinous lustre; (*c*

dull olive-green and mountain-green; (*d*) brick-red. Includes *Semiopal* (Halbopal *Wern.*, Bergm. J., 375, 1789); also (*e*) *Hydrophane*, which is translucent, whitish, or light-colored, adheres to the tongue, and becomes more translucent or transparent in water (to which the name, from *ὕδωρ*, *water*, and *φαίνω*, *to make clear*. alludes). a very common quality of opal. (*f*) *Forcherite* (Aichhorn, Wien. Ztg. Abendbl., Jul. 11, 1860); an orange-yellow opal, colored by orpiment; G.=2·17 Maly (J. pr. Ch., lxxxvi. 501). It is from Knittenfeld, in Upper Styria.

5 *Cacholong* (Kaschtschilon *of Kalmucks* and *Tartars* [=beautiful stone], Kascholong *Germ.* Perlmutter-opal *Karst.*, Tab., 1808). Opaque, bluish-white, porcelain-white, pale-yellowish or reddish; often adheres to the tongue, and contains a little alumina.

6. *Opal-agate.* Agate-like in structure, but consisting of *opal* of different shades of color.

7. *Menilite* (Pechstein de Menil Montant *Delarbre & Quinquet*, J. de Phys., xxxi. 219, 1787; Menilite *de Saussure*, Delameth. T. T., ii. 169, 1797. Leberopal *Karst.*, Tab., 24, 1800). In concretionary forms, tuberose, reniform, etc., opaque, dull grayish, grayish-brown, occurring imbedded in a shaly argillaceous deposit.

8. *Jasp-opal* (Karst. Tab., 26, 1808; Opal-jasper, Eisenopal, *Hausm.*, Handb., 428, 1813). Opal containing some yellow oxyd of iron and other impurities, and having the color of yellow jasper with the lustre of common opal.

9. *Wood-opal* (Holz-opal *Germ.*). Wood petrified by opal.

10 *Hyalite* (Mullerisches Glas [=Muller's Glass, after the discoverer]; Hyalit *Wern.*, Hoffm. Min., ii. *a*, 134, 1812, *Karst.*, Tab., 22, 1800; Gummistein *Blumenb.*, Nat., 553; Glasopal *Hausm.*, Handb., 424, 1813). Clear as glass and colorless, constituting globular concretions, and also crusts with a globular, reniform, botryoidal, or stalactitic surface; also passing into translucent, and whitish.

11. *Fiorite*, *Siliceous Sinter* (Kieselsinter *Germ.; Santi*, Viaggio al Montomiata, Pisa, 1795, Crell's Ann., ii. 589, 1796; *Thomson*, J. de Phys., xxxix. 407, 1791, Breve Notizia di un Viaggiatore sulle Incrost. Sil. termali d'Italia, etc., 1795, Crell's Ann., i. 108, 1796, Bibl. Brittan, 185, 1796 (? name fiorite here given); *Pfaff.*, Crell's Ann., ii. 589, 1796; Resinite termogino (*Ital.*). Includes translucent to opaque, grayish, whitish, or brownish incrustations, porous to firm in texture; sometimes fibrous-like or filamentous, and, when so, pearly in lustre (then called *Pearl-sinter*); formed from the decomposition of the siliceous minerals of volcanic rocks about fumaroles, or from the siliceous waters of hot springs. It graduates at times into hyalite. (*a*) The original *fiorite* (or pearl-sinter), as described by Thomson, occurs in tufa in the vicinity of Santa Fiora, Italy, and also on Ischia, and at the Solfatara near Naples, in globular, botryoidal, and stalactitic concretions, pearly in lustre. Thomson also mentions (1791) a similar incrustation as formed from the hot waters of the Sasso lagoons. It was referred by Werner to hyalite in 1816 (Hoffmann). (*b*) The *Michaelite* (J. W. Webster, Am. J. Sci., iii. 391, 1821) is similar, from the island of St. Michaels, one of the Azores, where it occurs in snow-white incrustations, capillary or filiform in structure, pearly in lustre, with G.=1·866. (*c*) *Geyserite* (Kieseltuff (fr. Geysers) *Klapr.*, Beitr., ii. 109, 1797; Geysirite *Delameth.*, Min., 1812; Damour, Bull. G. Fr., 1848, 157) constitutes concretionary deposits about the Iceland geysers, presenting white or grayish, porous, stalactitic, filamentous, cauliflower-like forms; also compact-massive, and scaly-massive; H.=5; rarely transparent, usually opaque; sometimes falling to powder on drying in the air.

12. *Float-stone* (Quartz nectique, *H.*, Tr., ii. 1801; Schwimmstein *Germ.*). In light concretionary or tuberose masses, white or grayish, sometimes cavernous, rough in fracture. So light, owing to its spongy texture, as to float on water. The concretions sometimes have a flint-like nucleus.

13. *Tripolite* (Trippel, Terra Tripolitana (fr. Tripoli, in part), *Wall.*, 32, 1747. Infusorial earth; Bergmehl, Kieselmehl, Kieselguhr, *Germ.* Farina fossilis. Randanite *Salvetat*, Ann. Ch. Phys., III. xxiv. 348, 1848). Formed from the siliceous shells of Diatoms and other microscopic species, as first made known by Ehrenberg, and occurring in deposits, often many miles in area, either uncompacted, or moderately hard. (*a*) *Infusorial Earth*, or *Earthy Tripolite*, a very fine-grained earth looking often like an earthy chalk, or a clay, but harsh to the feel, and scratching glass when rubbed on it. (*b*) *Randanite*, a kaolin-like variety from Ceyssat near Randan, in Dept. Puy de Dome, and from Algiers, containing 9 to 10 p. c. of water. A deposit at Santa Fiora in Tuscany was made known by G. Fabbroni in 1794 (Giorn. Fis.-med. di D. Brungnatelli, p. 154; Crell's Ann., ii. 199, 1794; Bergmehl v. Santa Fiora *Klaproth*, Beitr., vi. 348). It consists of a grayish-white, loose, mealy earth; Fabbroni states that he made bricks of it which would float like those which Pliny described as made in Spain from a sort of pumice-like earth (xxxv. 49), and supposes the material the same. Ehrenberg has shown it to be an infusorial earth. (*c*) *Tripoli slate* (Polishing slate, Polierschiefer, Tripelschiefer, Saugkiesel, Klebschiefer, *Germ.*), a slaty or thin laminated variety, fragile; G.=1·909–2·08. Often much impure from mixture with clay, magnesia, oxyd of iron, etc. (*d*) *Alumocalcite* (fr. Eibenstock, Breith., Char., 97, 326, 1832) is a milk-white material, having a hardness of only 1 to 1½; G.=2·174; it may be a variety of tripolite, containing a little lime and alumina.

Analyses: 1, Klaproth (Beitr., ii. 151); 2, v. Kobell (Char., 252, 1830); 3–6, Damour (Bull. G

Fr., II. v. 162, 1848); 7, Klaproth (l. c., iv. 156); 8, id. (ib., ii., 157); 9, Forchhammer Pogg., xxxv 331); 10, G. J. [a] Somewhat ammoniacal. [b] With some carbonaceous material. [c] Na Cl. [d] With some magnesia. [e] Carbonate of lime. [f] Also ammonia 0·01.

Randanite of Salvetat (anal. 48) corresponds to the formula $\ddot{S}i^3 \dot{H}$ (=$\ddot{S}i$ 90·9, $\dot{H}$ 9·1) when dried at 16° C., and $\ddot{S}i^6 \dot{H}$ (=$\ddot{S}i$ 95·3, $\dot{H}$ 4·7) when dried at 100° C. The precious opal of Hungary, analyzed by v. Kobell (anal. 2), lost 7·5 p. c. on drying at a low heat, and the rest of the water, or 3·44 p. c., on ignition.

Pyr., etc.—Yields water. B.B. infusible, but becomes opaque. Some yellow varieties, containing oxyd of iron, turn red.

Obs.—Occurs filling cavities and fissures or seams in igneous rocks, porphyry, and some metallic veins. Also imbedded, like flint, in limestone, and sometimes, like other quartz concretions, in argillaceous beds; also formed from the siliceous waters of some hot springs; also resulting from the mere accumulation, or accumulation and partial solution and solidification, of the siliceous shells of infusoria—which consist essentially of opal-silica. The last mentioned is the probable source of the opal of limestones and argillaceous beds (as it is of flint in the same rocks), and of part of that in igneous rocks. It exists in most chalcedony and flint. Being like quartz in origin, it is natural that the two should be often mixed together. Common opal and hyalite are products of the decomposition of a Roman cement at the hot springs of Plombières in France.

Precious opal occurs in porphyry at Czerwenitza, near Kashau in Hungary, at Frankfort, and at Gracias a Dios in Honduras. *Fire opal* occurs at Zimapan in Mexico; Faröe; near San Antonio, Honduras. *Common opal* is abundant at Telkebanya in Hungary; near Pernstein, Luckau, and Smrezet in Moravia; in Bohemia; at Kosemütz in Silesia; Hubertsburg in Saxony; Stanzenberg and Quegstein in Siebengebirge; Steinheim near Hanau; in Faröe, Iceland; the Giant's Causeway, and the Hebrides; also within ½ m. and to the S.W. of the watering-place at Vourla, the harbor of Smyrna, along with yellow jasper and hornstone, imbedded in a low ridge of yellowish compact limestone; of a wax-yellow and grayish-green color, occasionally white, at the Giant's Causeway. *Hyalite* occurs in amygdaloid at Schemnitz, Hungary; in clinkstone at Waltsch, Bohemia. *Wood opal* forms large trees in the pumice conglomerates of Saiba, near Neusohl; Kremnitz, Hungary; Faröe; near Hobart Town, Tasmania; and in many other regions of igneous rocks.

The Luneberg earth contains many species of infusoria, and is 10 to 18 ft. thick.

In U. S., *hyalite* occurs sparingly in N. York, at the Phillips ore bed, Putnam Co., in thin coatings on granite; rarely in N. C., Cabarrus Co., with the auriferous quartz; in Georgia, in Burke and Scriven Cos., lining cavities in a siliceous shell-rock; in Washington Co., good fire opal; at the Suanna spring, Florida, small quantities of siliceous sinter.

The precious opal, when large, and exhibiting its peculiar play of colors in perfection, is a gem of high value. It is cut with a convex surface.

233. JENZSCHITE.—A *second* modification of amorphous silica is mentioned above (p. 194) as announced by G. Jenzsch. The facts may receive other explanation. For the present the opals supposed to represent it may be included under the above name. The characteristic is a specific gravity of 2·6, like quartz-silica, while soluble in a hot solution of caustic potash. The kinds here referred to are a white cacholong from Hüttenberg in Carinthia, G.=2·591; from Hutberg, near Weissig, in amygdaloid, G.=2·633—2·647; from the porphyry of Regensberg, G.=2·620; from Brazil, G.=2·596. They are generally associated with chalcedony, and Jenzsch regards them as a result of its alteration.

II. TERNARY OXYGEN COMPOUNDS.

1. SILICATES.

A. ANHYDROUS SILICATES.

The following are the general subdivisions of the Anhydrous Silicates:

I. BISILICATES. Oxygen ratio for the bases and Silica 1 : 2.

II. UNISILICATES. Oxygen ratio for the bases and Silica 1 : 1.

III. SUBSILICATES. Oxygen ratio for the bases and Silica 1 : less than 1; mostly 1 : $\frac{2}{3}$; but also 1 : $\frac{1}{2}$, and 1 : $\frac{3}{4}$.

These subdivisions are essentially the same that were brought forward in the last edition of this work. The section of Tersilicates has, however, disappeared, the species hitherto arranged under that head being proved to have no existence; and the few Sesquisilicates, and the Micas and Feldspars, are added to the Unisilicates.

Constitution and Formulas of Silicates.—The bases in the Silicates comprise various elements of Series I. (see p. 2) in their different states of oxydation, protoxyd, sesquioxyd, or deutoxyd, and possibly tritoxyd; namely, K, Na, Li, Th, Ca, H, Ba, Sr, Ca, Mg, Ce, La, Di, Fe, Mn, Cr, Al, and rarely also Zn, Ni, Co, Ti; and in a few cases boron, of Series II., in the tritoxyd state. The element silicon is so strongly negative, that in its oxygen combinations all other elements present are relatively basic.

The basic elements enumerated, when in the same state of oxydation, are mutually replaceable; and, as the analyses beyond illustrate, 8 or 10 often occur in the same compound, combined either in simple, or indeterminate, ratios. But while in general thus replacing one another, there are certain groups, as, for example, the Feldspar and Scapolite, in which $\ddot{\text{Al}}$ is not replaced by $\bar{\text{Fe}}$, nor $\dot{\text{Ca}}$, $\dot{\text{Na}}$, $\dot{\text{K}}$ by $\dot{\text{Mg}}$, or $\dot{\text{Fe}}$, the presence of the latter ingredients being an irregularity, and proof of mixture or alteration.

The basic elements are also mutually replaceable when in *different* states of oxydation, under the law that parts equal in power of combination with oxygen are equivalent or isomorphous, that is, *the replacing power equals the combining power*. Thus $3\,R\,O\ (=R^3\,O^3)$, $R^2\,O^3$, $\frac{3}{2}\,R\,O^2\ (=R^{\frac{3}{2}}\,O^3)$, $\frac{3}{5}\,R^2\,O^5$, $R\,O^3$ are replaceable; and so also are $R^2\,O^2\ (=2\,R\,O)$, and $R\,O^2$; for the basic metal is combined with an equal amount of oxygen, 3 atoms in the former group, and 2 in the latter. The basic metals of these different oxyds by themselves represent so many different states corresponding to the states of oxydation, and are therefore equivalents in combination. The above formulas, if divided by 3, become reduced to the protoxyd form $R\,O$, $R^{\frac{2}{3}}\,O$, $R^{\frac{1}{2}}\,O$, $R^{\frac{2}{5}}\,O$, $R^{\frac{1}{3}}\,O$, and the expressions for the different states of the basic metals, to R, $R^{\frac{2}{3}}$, $R^{\frac{1}{2}}$, $R^{\frac{2}{5}}$, $R^{\frac{1}{3}}$. The first three of these states have been denominated in a note to page 2, and in the Introduction, p. xv, the *alpha*, *beta*, and *gamma* states; the expressions are correspondingly written αR, βR, γR, δR, ϵR. $\alpha R\,O$ equals $R\,O$, or a protoxyd. So also $\beta R\,O=\frac{1}{3}(R^2\,O^3)$, or a third of a sesquioxyd; $\gamma R\,O=\frac{1}{2}(R\,O^2)$, or half of a deutoxyd; and $\epsilon R\,O=\frac{1}{3}(R\,O^3)$, or one-third of a tritoxyd. αR, βR, γR, δR, ϵR, are mutually replaceable, or equivalent in substitutions.

The *Bisilicates* come under a single general formula, which may either have the form A, or that of B. The α is here dropped, it being unnecessary.

A. $(\dot{R}^3, \bar{R}, \ddot{R}^{\frac{3}{2}}, \dddot{R})\,\ddot{Si}^3$ B. $(R\,O, \beta R\,O, \gamma R\,O, \epsilon R\,O)\,\ddot{Si}$

The *Unisilicates* have the corresponding formula:

A. $(\dot{R}^3, \bar{R}, \ddot{R}^{\frac{3}{2}}, \dddot{R})^3\,\ddot{Si}^3$ B. $(R\,O, \beta R\,O, \gamma R\,O, \iota R\,O)^2\,\ddot{Si}$

As deutoxyds and tritoxyds occur as bases only in a few minerals, these general formulas for the ordinary species are:

Bisilicates	A. $(\dot{R}^3, \bar{R})\,\ddot{Si}^3$	B. $(R\,O, \beta R\,O)\,\ddot{Si}$
Unisilicates	$(\dot{R}^3, \bar{R})^2\,\ddot{Si}^3$	$(R\,O, \beta R\,O)\,\ddot{Si}$

If the latter formulas (B) be multiplied by 3, after substituting the value of β R, they become the exact equivalent of the former; but they are not necessarily the better for this multiplication, because chemistry is not yet able to decide positively whether, in the different cases, the multiplier should not rather be 6, 9, or some other number.

In the *new system* of chemistry the formulas of the Bisilicates and Unisilicates, in their most general form, are written in the following manner, essentially, by writers on the subject, except that the letter R is here used with the Greek letters to express the metal in the different states of oxydation:[*]

Bisilicates $$\left.\begin{matrix} Si\,\Theta \\ R^2, \bar{R}, \beta\bar{R}, \gamma\bar{R} \end{matrix}\right\}\Theta^3$$ Unisilicates $$\left.\begin{matrix} Si \\ R^2, \bar{R}, \beta\bar{R}, \gamma\bar{R} \end{matrix}\right\}\Theta^4$$

These formulas may be more conveniently written in a single line, as follows; and to facilitate a comparison, the formulas of the older system are here added:

	Old system.	Old system modified.	New system.
Bisilicates	$(\dot{R}^3, \bar{R})\,\ddot{Si}^3$	$(RO, \beta R\,O)\,\ddot{Si}$	$Si\,\Theta\vert\Theta_2\Vert(R, \bar{R}, \beta\bar{R})$
Unisilicates	$(\dot{R}^3, \bar{R})^2\,\ddot{Si}^3$	$(RO, \beta R\,O)^2\,\ddot{Si}$	$Si\vert\Theta_4\Vert(R_2, \bar{R}, \beta\bar{R})_2$

By means of fractions prefixed to the Rs or $\bar{R}$s, the ratios of the constituents may be expressed, as in the older formulas.

The *Subsilicates* vary in formula according to the varying ratios, as presented beyond (p. 362) The only silicates having the basic metals in the sesquioxyd state alone occur among the Subsilicates.

Besides the silicates that are obviously Bisilicates and Unisilicates, there are others which, while bisilicate or unisilicate in type, contain a surplus of silica in serial ratios.

The *Feldspar* group is remarkable for its unity in crystallographic and all physical characters, evincing the profoundest isotypism; and yet the oxygen ratio for the bases and silica varies from 1 : 1 to 1 : 3. The fact that all the essential characters of a Feldspar appear in their perfection under the unisilicate ratio shows that the amount of silica of a Unisilicate is all that is required to make a Feldspar, and hence that the type is strictly *unisilicate;* and further, that the excess of silica must exist in the species in some state consistent with conformity to the unisilicate type. The amount of silica in the species of the Feldspar group *increases* with the *increasing proportion of alkali* in the mineral, from anorthite, a *Unisilicate without*, usually, *any alkali*, to albite and orthoclase, literal *Trisilicates*, with the protoxyd bases *solely alkaline.*

The *Micas* vary in the same way, being unisilicate strictly in the species containing the least alkali, and having a higher proportion as the alkali increases, and the highest in the lithia micas, in one of which the ratio is 1 : 2. The *Meionite* section of the Scapolite group is in *meionite* strictly unisilicate, without alkali, while *mizzonite* has much alkali and more silica in proportion than meionite, and *marialite* (which like mizzonite is hardly distinguishable from meionite in crystallographic or physical characters) is bisilicate, with the alkali constituting much the larger part of the protoxyd bases. The Scapolite section of the Scapolite group illustrates the same point. The special ratios for this and each of the preceding groups are stated in the general remarks preceding the section on the Unisilicates.

Among Bisilicates, *spodumene* is closely related to the Pyroxene group in crystallization and other characters, including the oxygen ratio for the bases and silica, although alumina and lithia are prominent constituents. *Pelalite* has the same crystallization (as shown by Descloizeaux) and the same constituents as spodumene, and therefore is also pyroxene-like in its fundamental characteristics; and yet it contains twice the proportion of silica, the oxygen ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$ in spodumene being 1 : 4 : 10, and in petalite 1 : 4 : 20, a contrast of great interest in this connection, as remarked by Descloizeaux. The amount of silica in spodumene shows what is essential to the type, and therefore proves that both are essentially Bisilicates. It differs from petalite in that the protoxyd bases include a little lime and protoxyd of iron (about *one-twelfth* of all the protoxyds, from the average of the best analyses, those of Rammelsberg, Hagen, and Smith & Brush), while in petalite they are purely alkaline.*

---

[*] R^2 stands for 2 of a monad element, as potassium, sodium, lithium, thallium, cæsium, rubidium, hydrogen, and $\bar{R}$ for other basic elements, as already explained. See also Am. J. Sci., II xliv 252, 261, and Introd., p. xv.

The Feldspars, Micas, and the Meionite and Scapolite groups are examples of a surplus of silica in species under the unisilicate type, and the Spodumene group under the bisilicate. In each the alkali present appears to be the determinative cause. The surplus silica above what the type requires may have one of the two following conditions: Either it may be (1) *part basic* (*half* of it under the unisilicate type, and *one-third* of it under the bisilicate type); or it may be (2) *all accessory* silica. The formula of albite, under the unisilicate type, to which it is shown above to belong, would be as follows, according to these two methods:

1st method $(\tfrac{1}{8}\dot{\text{N}}\text{a}^3+\tfrac{3}{8}\ddot{\overline{\text{Al}}}+\tfrac{1}{2}\ddot{\text{Si}}^{\frac{3}{2}})^2\,\ddot{\text{Si}}^3$, or $\text{Si}\|\Theta_4\|(\tfrac{1}{8}\text{Na}_2+\tfrac{3}{8}\beta\overline{\text{Al}}+\tfrac{1}{2}\gamma\text{Si})_2$

2d method $(\tfrac{1}{4}\dot{\text{N}}\text{a}^3+\tfrac{3}{4}\ddot{\overline{\text{Al}}})^2\,\ddot{\text{Si}}^3+3\,\ddot{\text{Si}}$, or $\text{Si}\|\Theta_4\|(\tfrac{1}{4}\text{Na}_2+\tfrac{3}{4}\beta\overline{\text{Al}})+\text{Si}\,\text{O})_2$

For other examples see the formulas of the Unisilicates beyond (p.

From the facts here explained it follows that the Mica and Feldspar groups should be annexed entire to the section of Unisilicates; and petalite to the section of Bisilicates. The intermediate silicates are thus mostly disposed of without the provision of other sections. Iolite has the O ratio for bases and silica of muscovite (or 1 : 1½), and its excess of silica above that of the Unisilicates may be of the same nature as in that species. The case of nephelite may be similar.

The *hydrous* species of silicates are here separated from the *anhydrous*, as in other divisions in the classification, because the course seems most convenient in the present imperfect state of chemical science. There is no criterion yet furnished for deciding upon the state of the water present, whether part, or all, or none, is basic; and until chemists have some means of reaching safe conclusions on this point, the true relations of the hydrous and anhydrous species cannot to any great extent be positively made out. Moreover there is often doubt as to whether the water present is simply hygrometric and accidental; or whether it exists as a result of incipient or advanced alteration of the mineral; or whether it belonged to the species from its origin; and these doubts still further complicate the subject.

In some silicates, as euclase for example, the water appears to be so plainly basic that the species have been arranged beyond with the anhydrous; and this is the beginning of a final disregard of the distinction which will probably before long be warranted.

In the descriptions of the silicates beyond, the chemical formulas given are those of the old system, as these are equally intelligible to all chemists. But in the tables preceding the general divisions of the species, the new formulas are introduced as well as the old.

Note on the History of the Silicates. In the work of the Swedish mineralogist Wallerius, of 1747, silicates as such are unrecognized, and the only species of those now so called which are described, are the gems that passed under the names of *emerald*, *beryl*, *topaz*, *hyacinth*, *chrysolite*, *garnet*; *clays* of various kinds and names; *mica*, *talc*, *serpentine*, *amianthus*, *asbestus*, *feldspar*, and the convenient pocket for various undetermined heavy stones, named *Corneus*—the *Hornbärg* of the Swedish mineralogist, and *Roche de Corne* of his French translator, and which embraced *Skörl* (*Schörl* of the Germans) as a prominent part of it. Quartz (Kieselsten, or Silex) in its many varieties, with opal, made up a large part of the non-metallic division of the science, occupying 30 pages out of 200. Feldspar is placed in the genus Spatum, as *Spatum pyrimachum* (or scintillating spar) along side of fluor, Iceland spar, and heavy spar; and sapphire and the other precious stones are in the group of Gems. All of these species excepting feldspar had special names in Pliny's time; and feldspar is distinctly referred to in Agricola as "Silex ex eo ictu ferri facile ignis elicitur, in cubis aliisque figuris intersectis constans" (p. 314, 1546).

Cronstedt's work of 1758 includes with the preceding the species *Zeolite*, a recent discovery of his own (1756); but adds no others. He shows however his acumen in making his group of *Kiesel-Arter* (siliceous minerals) to include not only the varieties of quartz, but also feldspar and the gems above enumerated (and his adding to it the diamond is not surprising). Garnet and schörl are left outside, and make the two species of his *Granat-Arter*; *Mica* (Glimmer-Arter) and *Asbestus* (Asbest-Arter), with Ler-Arter (clay minerals), are the other independent groups. Transparent tourmalines from Ceylon were among the gems of the day, having been first introduced into Europe in 1707 or before, but they are not distinctly mentioned by Cronstedt or Wallerius.

---

* See further on this subject a paper by the author in Am. J. Sci., II. xliv. 398, 1867.

The group of Schörl increased in its varieties for the next twenty-five years, and after that became prolific in species, and much of the history of mineralogy is involved in its various phases. The following observations make, therefore, an introduction to the synonymy of many minerals beyond.

The *Corneus*, or *Hornbürg*, of Wallerius included a variety of hard, cheap or worthless stones, rather heavy, mostly of dark colors from black to dull green. The name alludes to a resemblance to horn in the aspect of some of the kinds. To *Corneus solidus* belonged the massive, compact, flinty rocks of black and lighter shades; also petrosilex (or *Hälleflinta* of the Swedes, which means *false flint*) of different shades; and massive hornblende ("granulis compactis"), though the name hornblende was, by a mistake of its German use, given by Wallerius to a black zinc-blende alone. His *Corneus fissilis* embraced lamellar forms of hornblende and pyroxene, and some slaty rocks. White *Corneus crystallisatus* was his *Skiörl*, which comprised opaque tourmalines, and other prismatic minerals of black, brown, green, and reddish colors, as hornblende, actinolite, and perhaps pyroxene, and at the head of the list basalt, and basanite or Lydian stone.

Cronstedt's *Skörl* made up his genus *Basaltes*, and was nearly synonymous with the *Corneus crystallizatus* of Wallerius. Its varieties were better defined; and to massive, lamellar, and columnar hornblende, actinolite and pyroxene and crystallized opaque tourmaline were added; and in an appendix to the species, cruciform staurotide. The name *Hornblende* is applied only to the massive variety or rock which Cronstedt made a *bole*, and called *Bolus induratis particulis squamosis*; it probably covered other similar stones.

J. Hill in his work on Fossils, published in London, and according to the title page in 1771 (though de Lisle says it was not issued until 1772), says of the "Shirls," that "as to size we see them from that of barley corn up to the Giant's Causeway," and the columns of the latter he calls "Irish Shirl," or "Basaltes Hibernicus." The group contains also macle or chiastolite from Andalusia, besides tourmaline, etc.

In the editions of Wallerius of 1772 and 1778 there is a little advance beyond the first as regards the number and classification of the species. Cronstedt is followed in the position of feldspar, and in the name "Basaltes" for the schörls; and Corneus is restricted to massive, fibrous, and coarse columnar stones, among which stands "hornblende" as *Corneus spathosus*, and "trapp" as *Corneus trapezius*.

At this period de Lisle brought crystallography to bear on the subject. But while making known new distinctions, he did not appreciate their full value, or the precision required for thorough work. As a consequence, the group of Schörls (or Schorls, as he writes the word) in his later treatise of 1783, reached its greatest extension, although in a partly divided state. He early pronounced basaltic columns no crystals, and dropped off this excrescence. He showed in 1772 that the gem tourmaline, his *Transparent rhomboidal schorl*, was identical in form with the common black schorl. But still he made the latter a distinct *species*, his *Opaque rhomboidal schorl*, and included in it, along with black or opaque tourmaline, crystals of hornblende, augite, octahedrite from Oisans, rutile (needles in quartz), and, as a white variety, thin twins of albite, whose relation to feldspar he did not perceive; and even hexagonal nephelite from Vesuvius has a passing remark under this head. Axinite, then a novelty from Dauphiny, was made a short lenticular variety of *Transparent rhomboidal schorl*, or tourmaline, its *rhomboidal* planes proving to his eye the relationship. The massive mineral called *Hornblende*, or *Roche de Corne*, referred by Cronstedt to *Bole*, he annexes to Schorl as a massive or semicrystallized kind, but makes it a separate species, *Schorl argileux*, although apparently appreciating that it was little entitled to the distinction. *Schorl cruciforme* was his last species in the group, and to it were referred both andalusite and staurolite—the latter his *Pierre de croix*, with the prismatic angle of 130° by his measurement; and the former, *Macle basaltique*, with an angle of 95°. The garnets and schorls were placed in a common division, as done by Cronstedt, and garnet was made the first species, with tourmaline the second, and "cruciform schorl" the fifth. Garnet included the "white garnet," as it was called, of Vesuvius (leucite), first observed by Ferber in 1772. Besides these Silicates, de Lisle's work has its several groups of Gems, Feldspar, Argillaceous Minerals (embracing mica, asbestus, talc, serpentine), Zeolite, and Quartz. Labradorite, from Labrador (first brought to Europe about 1770), stands as a variety of feldspar, to which it had been referred by Werner; idocrase, of which many figures are given by him (first described and figured by Cappeler in 1722), meionite (hyacintes blanches), from Somma, and harmotome from Andreasberg (his *hyacinte blanche cruciforme*, made calcareous spar by v. Born in 1775, who first mentions and figures it, but a hyacinth-like *siliceous* species by Bergmann in 1780), are placed with zircon as kinds of *hyacinth*.

After de Lisle, as chemistry and crystallography made progress, the disintegration of the great Schorl group went rapidly forward, until the only thing left to it was common tourmaline; and now the name, once so important, has become a mere mineralogical relic. In Werner's system of 1789, as published by Hoffmann (Bergm. J., i. 369, 1789), Schörl includes only the species Tourmaline as it now stands. The *Kieselarten*, or Siliceous species (commencing with the diamond still), comprised the different gems; among which stands chrysoberyl (the modern), and, as distinct species, axinite, prehnite, hornblende of various kinds, with feldspar, mica, chlorite, the clays etc.; while under *Talkarten*, or Magnesian species, there are kyanite, actinolite, with asbestus talc, serpentine, nephrite, etc.

Silica was first proved to be a chemical constituent of many mineral species by Bergmann; and in his Opuscula (1780) and his Sciagraphia Regni Mineralis (1782) he distinguishes, after analyses by himself (made by fusion with potash, a method of his own), the following minerals as siliceous compounds of alumina, with or without lime or magnesia, namely, topaz, emerald, garnet, schörl (black tourmaline), hornblende, mica, zeolite from Iceland, feldspar, and the clays; and as essentially magnesian silicates, containing lime and a little iron, and little or no alumina, actinolite, asbestus (mountain cork and mountain leather), amianthus, steatite. These were the investigations that commenced the disbanding of the schorls, and before Werner's system of 1789 was published, many other analyses, more or less imperfect, had already been made by Wiegleb, Klaproth, Achard, Heyer, Mayer, Höpfner, Pelletier, and other chemists of the day.

The word *Schörl* of the Germans has been supposed to be derived from the name of a locality of the mineral, *Schorlau* (meaning Schörl-village) in Germany. But Prof. Naumann says (in a recent letter to the author) that it is more likely that the name is a miner's term of unknown origin, and that the village got its name from the occurrence there of the schörl. Some German mineralogists have pronounced it of Swedish origin, and as first used by Cronstedt. But it occurs in Brückmann's Magnalia Dei, published at Braunschweig in 1727, on page 175, where it is spelt *schirl*. It exists also still earlier, as the author has found, in Ercker's Aula Subterranea, first published in 1595, *shurl* and wolfram being spoken of as among the rejected material in auriferous washings; and again in the yet older work of Gesner, De Rerum Foss, etc., 1565, p. 87, where schurl (misspelt? *schrul*) is given as the German for "Lapilli nigri steriles" of a tin vein, which, "quando cum lapillis plumbi candidi [or tin] coquuntur plumbum consumunt," etc.; again, in Matthesius's Sarepta, 1562, in the 9th "Predigt," where "Schurl" is quite fully described, and also, in the next paragraph, "Wolffrumb." The name Schörl (or Schurl) was at that time used quite indefinitely for the *sterile* (or metallurgically worthless) black little stones ("nigri lapilli") accompanying tin ore and gold, especially the former; and, as they were among the refuse of the ore-washings, Adelung suggests that Schörl may have come from the old German word *Schor*, meaning *impurities*, or *refuse*.

General Pyrognostic Characters of the Silicates. In the systematic pyrognostic examination of silicates, the following points should be particularly noticed:

1. If *in the closed tube* the substance prove hydrous, the water given out should be tested as to whether it is acid or alkaline. If acid, this may be evidence that the mineral contains fluorine; and if alkaline, that possibly the substance is an altered mineral. In the former case, the water should be (*a*) tested with Brazil-wood paper; (*b*) the tube should be carefully observed, to ascertain whether it has been dimmed or etched by the action of the fluorine; and, further (*c*), the test for fluorine, by fusing in the open tube with salt of phosphorus, should be employed.

2. In the examination B.B. *on charcoal* it should be noted that silicates containing much iron become magnetic; and silicates of the oxyds of iron, copper, etc., yield metallic buttons on fusion with soda.

3. In examining the mineral *in the platinum-pointed forceps*, it should always be treated in O.F. to ascertain (*a*) whether it imparts a color to the flame; and (*b*) its fusibility, remembering that some silicates, infusible in O.F., become fusible by a reduction of their bases to a lower state of oxydation in R.F. It is to be noted that (*c*) only infusible and light-colored silicates can be tested for alumina B.B. with cobalt solution, since all fusible silicates, not containing metallic oxyds, give a cobalt-blue glass; (*d*) a small amount of soda in a silicate may, by the intense yellow color it imparts to the flame, mask a much larger percentage of potash or other alkali, as in the case of some varieties of potash-feldspar (orthoclase); (*e*) when silicates, like hornblende, pyroxene, or garnet, contain various isomorphous bases, the fusibility of the species has a wide range; in garnet, for example, it varying from the easy fusibility of almandine to the infusibility of ouvarovite; (*f*) a few silicates react alkaline after ignition or fusion.

4. In *treatment with the fluxes*, it is to be noted (*a*) that most silicates are dissolved in soda with effervescence. (*b*) If sulphur or sulphuric acid is present, the mineral gives in R.F. a sulphid which reacts for sulphur when moistened and placed on a surface of silver. (*c*) Borax dissolves silicates; and if they contain metallic oxyds, the nature of these oxyds may be determined by treatment in O.F. and R.F. (*d*) Salt of phosphorus decomposes almost all silicates, dissolving the bases, and leaving a gelatinous skeleton of insoluble silica; and if metallic oxyds are present, they may also impart a characteristic color to the bead in O.F. and R.F.

I. BISILICATES.

ARRANGEMENT OF THE SPECIES.

I. AMPHIBOLE GROUP. Crystallization anisometric, either orthorhombic or clinohedral, and angle of prism not 120°.

(1) PYROXENE SUBGROUP. $I \wedge I = 86° - 88°$. Composition $\dot{\mathrm{R}}\,\ddot{\mathrm{Si}}$, or $(\dot{\mathrm{R}}^3, \dddot{\bar{\mathrm{R}}})\,\ddot{\mathrm{Si}}^3$; and when both $\dot{\mathrm{R}}$ and $\dddot{\bar{\mathrm{R}}}$ are present, ratio of $\dot{\mathrm{R}}^3 : \dddot{\bar{\mathrm{R}}} = 3:1$ to $1:2$.

a. Crystallization orthorhombic. Optic-axial plane normal to a diagonal section; one bisectrix normal to the base. Contain little or no lime.

234. ENSTATITE	$\dot{\mathrm{Mg}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{Mg}$
235. HYPERSTHENE	$(\dot{\mathrm{Mg}}, \dot{\mathrm{Fe}})\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{Mg}, \mathrm{Fe}$
236. DIACLASITE	$(\dot{\mathrm{Mg}}, \dot{\mathrm{Fe}}, \dot{\mathrm{Ca}})\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{Mg}, \mathrm{Fe}, \Theta\mathrm{a}$

b. Crystallization monoclinic. Optic-axial plane normal to a diagonal section; bisectrix not normal to the base.

α Bases mainly or wholly protoxyds; much lime; little or no alkali.

237. WOLLASTONITE	$\dot{\mathrm{Ca}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \Theta\mathrm{a}$
238. PYROXENE A.	$\dot{\mathrm{R}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{R}$
B.	$\dot{\mathrm{R}}\,(\ddot{\mathrm{Si}}, \dddot{\bar{\mathrm{Al}}}{}^{\frac{2}{3}})$	$(\mathrm{Si}, \beta\mathrm{Al}_2)\Theta \vert \Theta_2 \vert \mathrm{R}$

β Bases largely sesquioxyds; little or no lime; much alkali.

239. ÆGIRITE	$(\frac{1}{2}\,\dot{\mathrm{R}}^3 + \frac{1}{2}\dddot{\bar{\mathrm{Fe}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{1}{2}\,(\mathrm{Na}_2, \mathrm{R}) + \frac{1}{2}\beta\mathrm{Fe})$
240. ACMITE	$(\frac{1}{3}\,\dot{\mathrm{R}}^3 + \frac{2}{3}\,\dddot{\bar{\mathrm{Fe}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{1}{3}\,(\mathrm{Na}_2, \mathrm{R}) + \frac{2}{3}\beta\mathrm{Fe})$

c. Crystallization triclinic. Optic-axial plane not normal to one of the diagonal sections, or to the base.

241. RHODONITE	$\dot{\mathrm{Mn}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{Mn}$
242. BABINGTONITE	$(\frac{3}{4}\,\dot{\mathrm{R}}^3 + \frac{1}{4}\,\dddot{\bar{\mathrm{Fe}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{3}{4}\,\mathrm{R} + \frac{1}{4}\beta\mathrm{Fe})$

(2) SPODUMENE SUBGROUP. $I \wedge I = 86° - 88°$. Composition $(\dot{\mathrm{R}}^3, \dddot{\bar{\mathrm{R}}})\,\ddot{\mathrm{Si}}^3$; and $\dot{\mathrm{R}}^3 : \dddot{\bar{\mathrm{R}}} = 1:4$; $\dot{\mathrm{R}} = \dot{\mathrm{Na}}, \dot{\mathrm{Li}}$, with some $\dot{\mathrm{Ca}}$, $\dot{\mathrm{Fe}}$ in Spodumene.

243. SPODUMENE	$(\frac{1}{5}\,\dot{\mathrm{R}}^3 + \frac{4}{5}\,\dddot{\bar{\mathrm{Al}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{1}{5}\,(\mathrm{R}_2, \mathrm{R}) + \frac{4}{5}\beta\mathrm{Al})$
244. PETALITE	a. $(\frac{1}{5}\,\dot{\mathrm{R}}^3 + \frac{4}{5}\,\dddot{\bar{\mathrm{Al}}})\,\ddot{\mathrm{Si}}^3 + 3\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{1}{5}\,\mathrm{R}_2 + \frac{4}{5}\,\beta\mathrm{Al}) + \mathrm{Si}\,\Theta_2$
	b. $(\frac{3}{5}\,(\frac{1}{5}\,\dot{\mathrm{R}}^3 + \frac{4}{5}\,\dddot{\bar{\mathrm{Al}}}) + \frac{2}{5}\,\ddot{\mathrm{Si}}{}^{\frac{3}{2}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{3}{5}\,(\frac{1}{5}\,\mathrm{R}_2 + \frac{4}{5}\beta\mathrm{Al}) + \frac{2}{5}\,\gamma\mathrm{Si})$

(3) AMPHIBOLE SUBGROUP. $I \wedge I = 123° - 125°$ (corresponding to *i*-2 of Pyroxene Subgroup).

a. Crystallization orthorhombic. Optical characters as under *a* above.

245. KUPFFERITE	$\dot{\mathrm{Mg}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert \mathrm{Mg}$
246. ANTHOPHYLLITE	$(\frac{3}{4}\,\dot{\mathrm{Mg}} + \frac{1}{4}\,\dot{\mathrm{Fe}})\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta \vert \Theta_2 \vert (\frac{3}{4}\mathrm{Mg} + \frac{1}{4}\,\mathrm{Fe})$

b. Crystallization monoclinic. Optical characters as under *b* above.

α Bases mainly or wholly protoxyds; little or no alkali.

247. AMPHIBOLE	A.	$\dot{\mathrm{R}}\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert\mathrm{R}$
	B.	$(\dot{\mathrm{R}}, \dot{\mathrm{H}})\,\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\mathrm{H}_2,\mathrm{R})$
	C.	$\dot{\mathrm{R}}\,(\ddot{\mathrm{Si}}, \ddot{\bar{\mathrm{Al}}}^{\frac{2}{3}})$	$(\mathrm{Si}, \beta\bar{\mathrm{Al}}_2)\,\Theta\vert\Theta_2\vert\mathrm{R}$

β Bases largely sesquioxyds; much alkali.

248. ARFVEDSONITE	$(\frac{3}{5}\,\dot{\mathrm{R}}^3 + \frac{2}{5}\,\ddot{\bar{\mathrm{Fe}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{3}{5}\,(\mathrm{Na}_2, \mathrm{R}) + \frac{2}{5}\,\beta\bar{\mathrm{Fe}})$
249. CROCIDOLITE		

Appendix to Amphibole Group

250. WICHTISITE	$\gamma(\frac{3}{4}\,\dot{\mathrm{R}}^3 + \frac{1}{4}\,\ddot{\bar{\mathrm{R}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{3}{4}\,(\mathrm{Na}_2, \mathrm{R}) + \frac{1}{4}\,\beta(\bar{\mathrm{Al}}, \bar{\mathrm{Fe}}))$
251. GLAUCOPHANE	$(\frac{3}{5}\,\dot{\mathrm{R}}^3 + \frac{2}{5}\,\ddot{\bar{\mathrm{R}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{3}{5}\,\mathrm{R} + \frac{2}{5}\,\beta\bar{\mathrm{R}})$
252. SORDAWALITE	$?\,(\frac{1}{2}\,(\dot{\mathrm{Mg}}, \dot{\mathrm{Fe}})^3 + \frac{1}{2}\,\ddot{\bar{\mathrm{Al}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{1}{2}\,(\mathrm{Mg}, \mathrm{Fe}) + \frac{1}{2}\,\beta\bar{\mathrm{Al}})$
253. TACHYLYTE		

II. BERYL GROUP. Crystallization hexagonal; not micaceous.

254. BERYL	$(\frac{1}{2}\,\dot{\mathrm{Be}}^3 + \frac{1}{2}\,\ddot{\bar{\mathrm{Al}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{1}{2}\,\mathrm{Be} + \frac{1}{2}\,\beta\bar{\mathrm{Al}})$
255. EUDIALYTE	$(\frac{3}{4}\,\dot{\mathrm{R}}^3 + \frac{1}{4}\,\ddot{\mathrm{Zr}}^{\frac{3}{2}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\frac{3}{4}\,(\mathrm{Na}_2, \mathrm{R}) + \frac{1}{4}\,\gamma\mathrm{Zr})$

III. POLLUCITE GROUP. Crystallization isometric.

256. POLLUCITE	$(\dot{\mathrm{Cs}}^3, \ddot{\bar{\mathrm{Al}}})\,\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\,\Theta\vert\Theta_2\vert(\mathrm{Cs}_2, \beta\bar{\mathrm{Al}})$

The fact of the *orthorhombic* form of some species of the Amphibole group (those so characterized above) was first ascertained by Descloizeaux through optical examination. Under PETALITE, the formulas *a* and *b* are those of the two methods explained on page 204.

234. ENSTATITE. Diallage métalloïde pt. *H.*, Tr., 1801. Bronzit *Karst.*, Klapr., Gehlen's J., iv. 151, 1807; *Karst.*, Tab., 40, 91, 1808; *Klapr.*, Beitr., v. 34, 1810. Blättriger Anthophyllit *Wern.*, 1808, Hausm. Entw., 1809. Bronzite. Chladnite *Shep.*, Am. J. Sci., II. ii. 381, 1846. Enstatit *Kenng.*, Ber. Ak. Wien, xvi. 162, 1855. Protobastit *A. Streng.*, ZS. G., xiii. 71, 1861.

Orthorhombic. $I \wedge I = 87°$ and 93°, Kenngott; 88° and 92°, Descloizeaux. Observed planes: *I*, *i-ĭ*, *i-ī*. $I \wedge i\text{-}\breve{i} = 133° 30'$, $I \wedge i\text{-}\bar{i} = 136° 30'$. Cleavage: *I*, easy; *i-ĭ*, *i-ī*, less so. Sometimes a fibrous appearance on the cleavage-surface. Also massive and lamellar.

H.=5·5. G.=3·1–3·3; 3·19, Vosges, Damour. Lustre a little pearly on cleavage-surfaces to vitreous; often metalloidal in the bronzite variety. Color grayish-white, yellowish-white, greenish-white, to olive-green and brown. Streak uncolored, grayish. Double refraction positive; optic-axial plane brachydiagonal; axes very divergent.

Comp., Var.—$\dot{\mathrm{Mg}}\,\ddot{\mathrm{Si}}$, or $(\dot{\mathrm{Mg}}, \dot{\mathrm{Fe}})\,\ddot{\mathrm{Si}}$; the $\dot{\mathrm{Fe}}$ atomically not over one-fourth of the protoxyds. $\dot{\mathrm{Mg}}\,\ddot{\mathrm{Si}}$=Silica 60, magnesia 40=100.

Var. 1. *With little or no iron; Enstatite.* Color white, yellowish, grayish, or greenish-white; lustre pearly-vitreous; G.=3·10–3·13. *Chladnite*, which makes up 90 p. c. of the Bishopville meteorite, belongs here and is the purest kind.

1. *Ferriferous; Bronzite.* Color grayish-green to olive-green and brown; lustre of cleavage-surface adamantine-pearly to submetallic or bronze-like. Ratio of $\dot{\mathrm{Mg}}$ to other protoxyds in anal. 3, 11¾ : 1; in 4, 8 : 1; in 5, 6½ : 1; in 6, 4½ : 1; in 7, 5¾ : 1; in 9, 4¾ : 1; in 11 (the so-called *protobastite*), 4¾ : 1.

Analyses: I., 1, v. Hauer (Ber. Ak. Wien, xvi. 165); 2, J. L. Smith (Am. J. Sci., II. xxxviii. 225); II. 3, Pisani (Descl. Min., i. 537); 4, Damour (Descl. Min., i. 45); 5, 6, v. Köhler (Pogg., xiii. 101); 7, 8. Regnault (Ann. d. M., III. xiv., 147), 9, v. Kobell (J. pr. Ch., xxxvi., 303); 10, Garrett (Am. J. Sci., II. xv. 333); 11, 12, A. Streng (ZS. G., xiii. 73, B. H. Ztg., xxiii. 54):

	12. "		54·15	3·04	12·17	—	28·37	2·87	0·49=101·34 Streng.

G., anal. 5, fr. Stempel near Marbourg, 3·241; 6, fr. Seefeldalpe in the Ultenthal, Tyrol, 3,258; 6, ib., 3·241; 8, fr. serpentine of Gulsen near Kraubat in Styria, 3·125; 11, from a rock at Baste, Harz, called melaphyre, 3·29.

Pyr., etc.—B.B. almost infusible, being only slightly rounded on the thin edges; F.=6. Insoluble in muriatic acid.

Obs.—Occurs near Aloysthal in Moravia, in serpentine (the variety had been considered scapolite); at the W. base of Mt. Bresouars in the Vosges, olive-green, in serpentine; in Pennsylvania, at Leiperville and Texas; at Kupferberg in Bavaria; at Baste in the Harz (*Protobastite*); and at the other localities mentioned. The bronzite also of Lettowitz and Goldenstein in Moravia, of Alpstein near Sontra in Hesse, of Cape Lizard in Cornwall, may belong here according to Descloizeaux; but their chemical and optical characters are not yet ascertained. The brown pyroxene-like mineral which is a prominent constituent of the rock called *Lherzolite*, from the department of Arriège, France, is referred here by Descloizeaux.

The bronzite of Leiperville afforded Descloizeaux prisms of 87° and 93°; and that of Texas, half a mile W. of the village, occurs in large foliated and fibrous masses; neither is submetallic in lustre. Descloizeaux first defined the limits of this species, as here laid down.

Named from 'ενστάτης, an *opponent*, because so refractory. The name *bronzite* has priority, but a bronze lustre is not essential, and is far from universal. Shepard's *chladnite* was so imperfectly and incorrectly described that the name cannot claim precedence; he made it a tersilicate of magnesia (l. c.).

Alt.—*Bastite* or *Schiller spar*, the original from Baste in the Harz, is regarded by Streng as altered protobastite or bronzite. G. Rose long since pronounced it a result of the alteration of some mineral of the pyroxene group. *Phæstine* Breith. is stated by Breithaupt to be altered bronzite or bronze-like pyroxene. Enstatite occurs altered to talc. See BASTITE, p. 469.

235. **HYPERSTHENE.** Labradorische Hornblende (fr. I. St. Paul) *Wern.*, Bergm. J., 376, 391, 1789. Diallage métalloide pt. *H.*, Tr., 1801. Hypersthène *H.*, Ann. Mus., ii. 17, 1803. Labrador Hornblende; Metalloidal Diallage pt. Paulit *Wern.*, 1812, Hoffm. Min., ii. 2, 143, 1815.

Orthorhombic. $I \wedge I=86°\ 30'$ and $93°\ 30'$. Cleavage: i-$\breve{i}$ perfect, I and i-$\bar{i}$ distinct but interrupted. Usually foliated massive.

H.=5—6. G.=3·392. Lustre somewhat pearly on a cleavage-surface, and sometimes a little metalloidal. Color dark brownish-green, grayish-black, greenish-black, pinchbeck-brown. Streak grayish, brownish gray

Translucent to nearly opaque. Brittle. Optic-axial plane brachydiagonal; axes very divergent; bisectrix negative.

Comp.—($\dot{\text{Mg}}$, $\dot{\text{Fe}}$) $\ddot{\text{Si}}$. $\dot{\text{Fe}}$ to $\dot{\text{Mg}}$=1 : 2 or above this; in anal. 1, 1 : 1·8; in 2, 1 : 1·4; =Silica 54·2, protoxyd of iron 21·7, magnesia 24·1=100. Analyses: 1, Damour (Ann. d. M., IV. v. 157): 2, Muir (Thom. Min., i. 202); 3, 4, Hunt (this Min., 4th ed., and Rep. Geol. Can., 1863, 468; 5, Streng (B. H. Ztg., xxiii. 54);

	$\ddot{\text{Si}}$	$\overset{\dots}{\bar{\text{Al}}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\bar{\text{H}}}$
1. Labrador	51·36	0·37	21·27	1·32	21·31	3·09	——=98·72 Damour.
2. Skye	51·35	——	33·92	——	11·09	1·84	0·50=98·70 Muir.
3. Chateau Richer	51·35	3·70	20·56	——	22·59	1·68	0·10 (ign.)=99·93 Hunt.
4. " "	51·85	3·90	20·20	*tr.*	21·91	1·60	0·20 (ign.)=99·66 Hunt.
5. Harzburg	52·38	3·90	18·23	——	22·22	3·55	0·56=101·34 Streng.

Breithaupt gives for $I \wedge I$ in the bronzite of Fichtelgebirge 88° and 92°.

Pyr., etc.—B.B. fuses to a black enamel, and on charcoal yields a magnetic mass. Partially decomposed by muriatic acid.

Obs.—Hypersthene occurs at Isle St. Paul, Labrador (anal. 1); at Chateau Richer and St. Adèle, Mille Isles, Canada (anal. 3, 4), grayish-black and brown, with the laminæ curved; at the Isle of Skye (anal. 2); in Greenland; at Farsund and elsewhere in Norway; and reported also from Penig in Saxony; Ronsberg in Bohemia; the Tyrol; Elfdalen in Sweden; Neurode in Silesia; in Thuringia; the Fichtelgebirge; Voigtland.

It is often associated with labradorite, constituting a dark-colored, granite-like rock, called *Hyperyte*.

Named from 'υπέρ and σθένος, *very strong*, or *tough*.

236. DIACLASITE. Gelber Schillerspath *Freiesleben*, Schill. Foss. Baste, 13, 1794. Talkartiger Hornblende, *Hausm.*, Nordd. Beitr. B. H., i. 15, 1806. Diaklas *Breith.*, Char., 58, 1823. Diaklasit *Hausm.*, Handb., 498, 1847.

Orthorhombic. $I \wedge I$=93° and 87°. Observed planes: I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, and 1, often in hexagonal plates. Cleavage: $i\text{-}\breve{i}$ perfect; $i\text{-}\bar{i}$ imperfect. Foliated massive.

H.=3·5—4. G.=3·054, Köhler. Lustre pearly and metalloidal on a cleavage-face. Color brass-yellow, greenish-gray. Streak greenish-gray or nearly uncolored. Transparent in thin laminæ, translucent. Feel somewhat greasy. Brittle. Optic-axial plane $i\text{-}\bar{i}$, axes very divergent; bisectrix negative.

Comp.—($\dot{\text{Mg}}$, $\dot{\text{Fe}}$, $\dot{\text{Ca}}$) $\ddot{\text{Si}}$, Köhler. Analyses: 1, Köhler (Pogg., xiii. 101); 2, A. Streng (B. H. Ztg., xxiii. 54):

	$\ddot{\text{Si}}$	$\overset{\dots}{\bar{\text{Al}}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\bar{\text{H}}}$
1. Baste	53·74	1·83	11·51	0·23	25·09	4·73	3·76=100·39 Köhler.
2. Harzburg	53·31	7·49	8·14	——	25·37	3·56	1·55, alk. 0·58, $\overset{\dots}{\bar{\text{Cr}}}$ 0·29=101·73 Streng.

Pyr., etc.—Same as for bronzite.

Obs.—In crystals or foliated masses imbedded in serpentine rock at Baste near Harzburg, associated with euphotide; also from the gneiss mountains of Guadarrama, Spain. Resembles bronzite, but the plane of the optical axis is macrodiagonal instead of brachydiagonal.

237. WOLLASTONITE. Tafelspath (fr. Dognatska) *Stütz*, Neue Einr. Nat. samml. Wien, 144, 1793. Tabular Spar. Schaalstein *Wern.*, 1803, Ludwig's Min Wern., ii. 212, 1804, Mohs Null Kab., ii. 1, 1804. Wollastonite *H.*, Tr., 1822. Vilnite (fr. Vilna) *Horodecki*, Descl. Min., ii. 554.

Monoclinic. C=69° 48′, $I \wedge I$=87° 28′, $O \wedge 2\text{-}i$=137° 48′; $a : b : c$= 0·4338 : 1 : 0·89789. Observed planes, O; vertical, $i\text{-}i$, $i\text{-}\frac{3}{2}$, $i\text{-}\frac{5}{4}$, I, $i\text{-}\frac{4}{3}$, $i\text{-}2$; clinodome, $2\text{-}\grave{i}$; hemidomes, $\frac{1}{2}\text{-}i$, $1\text{-}i$, $3\text{-}i$, $5\text{-}i$, $-\frac{1}{2}\text{-}i$, $-1\text{-}i$, $-3\text{-}i$, $-5\text{-}i$; hemi-

octahedral, 2, 2-2̆, —2, —2-2̆. Fig. 201 in the pyroxene or normal position, but with the edge *O*/*i-i* the obtuse edge; f. 202 in the position given the crystals by authors who make *i-i* the plane *O*, and 2-2̆ the plane *I*.

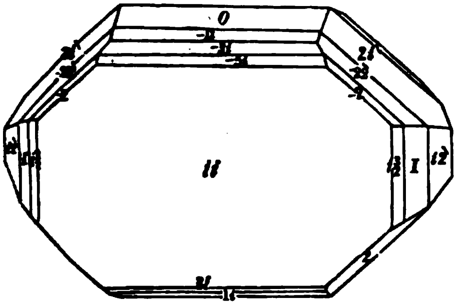
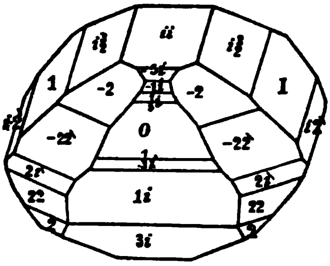
201



202



Vesuvius.

Rarely in distinct tabular crystals. Cleavage: *O* most distinct; *i-i* less so; 1-*i* and —1-*i* in traces. Twins: composition-face *i-i*. Usually cleavable massive, with the surface appearing long fibrous, fibres parallel or reticulated, rather strongly coherent.

H.=4·5—5. G.=2·78—2·9; 2·785—2·895, United States, Thomson; 2·805, Haidinger. Lustre vitreous, inclining to pearly upon the faces of perfect cleavage. Color white, inclining to gray, yellow, red, or brown. Streak white. Subtransparent—translucent. Fracture uneven, sometimes very tough. Optic-axial plane *i-i*; divergence 70° 40′ for the red rays; bisectrix of the acute angle negative; inclined to a normal to *i-i* 57° 48′, and to a normal to *O* 12°, Descl.

Comp.—$\dot{\mathrm{C}}\mathrm{a}\,\ddot{\mathrm{S}}\mathrm{i}$=Silica 51·7, lime 48·3=100. Analyses: 1, Stromeyer (Untersuch., 1, 356); 2, H. Rose (Gilb. Ann., lxxii. 70); 3, v. Kobell (J. pr. 16.	Grenville, Can.	53·05	Ḟe 1·20	——	45·74	——=99·99 Bunce.

Pyr., etc.—In the matrass no change. B.B. fuses easily on the edges; with some soda, a blobby glass, with more, swells up and infusible. With muriatic acid gelatinizes; most varieties effervesce slightly from the presence of calcite.

Obs.—Wollastonite is found in regions of granite and granular limestone; also in basalt and lavas.

Occurs in the copper mines of Oziklowa in Hungary; at Dognatzka and Nagyag; accompanying garnet, fluorite, and native silver, in limestone, at Pargas in Finland, and Kongsberg in Norway; occurs at Perhoniemi and Skräbböle, Finland; at Göckum in Sweden; at Vilna in Lithuania (vilnite); at Harzburg in the Harz; at Auerbach, in granular limestone; at Vesuvius, rarely in fine crystals; of a greenish-white color in lava at Capo di Bove, near Rome; in Ireland, at Dunmore Head, on the shores of the Mourne Mts.

In the United States, in *N. York*, at Willsborough, forming the sides of a large vein of garnet, traversing gneiss; at Lewis, 10 m. south of Keeseville, with colophonite, abundant; ¼ m. N. of Lewis Corners, with garnet and quartz; at Roger's Rock, near the line between Essex and Warren Cos., with garnet and feldspar; Diana, Lewis Co., about 1 m. from the Natural Bridge, in abundance, in large white crystals; at Booneville, Oneida Co., in boulders, with garnet and pyroxene. In *Penn.*, Bucks Co., 3 m. W. of Attleboro', associated with scapolite, pyroxene, and sphene. In *Mich.*, of a red color at the Cliff Mine, Kewenaw Point, Lake Superior, and on Isle Royale, a very tough variety, but now exhausted. In *Canada*, at Grenville, with sphene and green coccolite; at St. Jerome and Morin, C. E., with apatite, in large tabular masses of a fibrous structure.

Scacchi obtained from Vesuvian crystals (f. 202) *i-i* ∧ 3-*i*=135° 29′, *i-i* ∧ 1-*i*=95° 26′, *i-i* ∧ ½-*i* =78° 2′, *i-i* ∧ 1=111° 46′.

The form 2-*i* is usually made the vertical prism *I*, with *I* ∧ *I*=95° 36′ (or 35′). But the crystals in the position above given exhibit the near isomorphism with pyroxene.

Named after the English chemist, Wollaston; also called *tabular spar* from its lamellar forms and structure.

The *soda-tabular spar* of Thomson, from near Kilsyth, is pectolite.

237 A. EDELFORSITE. (Kalksilikat fr. Ædelfors, Kalktrisilikat, *Hisinger*, Ac. H. Stockh., 1838, 191, 1839. Edelforsit *v. Kob.*, Grundz., 202, 1838. Ædelforsit *Erdmann.*) Forchhammer has shown (Danske Ac. Forh., Ap. 1864) that Hisinger's mineral is an impure wollastonite, containing some quartz and feldspar, with often carbonate of lime and garnet. It occurs compact, part feathery fibrous, and part without any distinct crystalline structure. H. of portions 4; yet in other parts giving sparks with the steel, showing a hardness of 6—7. G.=2·584, Hisinger; 3·0, v. Kobell. Color white, grayish-white, or with a tinge of yellow. Hisinger and v. Kobell have analyzed the mineral, and made it a distinct species; yet their results are considerably discordant, like their determinations of the sp. gr. They obtained: 1, Hisinger (l. c.); 2, v. Kobell (J. pr. Ch., xci. 344):

	S̈i	Äl	F̈e	Ḟe	Ṁg	Ċa
1.	57·75	3·75	1·00	——	4·75	30·16, Ṁn 0·68=98·06 Hisinger.
2.	61·36	7·00	——	2·70	8·63	20·00, Ṁn *tr.*=99·69 Kobell.

Hisinger deduced the formula Ċa^3 S̈i^3, and v. Kobell 9 Ṙ^3 S̈i^3+Äl^3 S̈i^3.

The edelforsite of Gjellebäk in Norway has also been shown by Forchhammer (l. c.) to be essentially wollastonite. Hisinger obtained, as the mean of two analyses, S̈i 43·368, Ċa 38·433, Mn 4·962, Ḟe 1·434, C̈ 11·368. It has the aspect of tremolite. Forchhammer has found "okenite" of N. Greenland (Asbestagtig Okenit *Dr. Rink*) to be wollastonite.

Cleavage: *I* rather perfect, often interrupted; *i-i* sometimes nearly perfect; *i-i* imperfect; *O* sometimes easy. Crystals usually thick and stout. Twins: composition-face *i-i* (f. 214). Often coarse lamellar, in large masses, parallel to *O* or *i-i*. Also granular, particles coarse or fine; and fibrous, fibres often fine and long.

H.=5—6. G.=3·23—3·5, Lustre vitreous, inclining to resinous; some pearly. Color green of various shades, verging on one side to white or grayish-white, and on the other to brown and black. Streak white to gray and grayish-green. Transparent—opaque. Fracture conchoidal—uneven. Brittle. In crystals from Fassa, optic-axial plane *i-i*; divergence 110° to 113°; bisectrix of the acute angle positive, inclined 51° 6′ to a normal to *i-i* and 22° 55′ to a normal to *O*, Descl.

Comp., Var.—Bisilicate of different protoxyd bases, under the general formula $\dot{R}\ddot{Si}$; these bases ($\dot{R}$) being lime ($\dot{C}a$), magnesia ($\dot{M}g$), protoxyd of iron ($\dot{F}e$), protoxyd of manganese ($\dot{M}n$), and sometimes potash ($\dot{K}$), soda ($\dot{N}a$), and oxyd of zinc ($\dot{Z}n$). Usually two or more of these bases are present. The first three, lime, magnesia, and protoxyd of iron, are most common; but lime is the only one that is present always and in large percentage.

Besides the substitutions of different protoxyd bases for one another, these same bases are at times replaced by sesquioxyd bases ($\dddot{Al}$, $\dddot{Fe}$, $\dddot{Mn}$), though sparingly; and the silica occasionally by alumina. The species has therefore the general formula $(\dot{R}^3, \dddot{R})(\ddot{Si}, \dddot{Al}^{\frac{2}{3}})^3$, which may also be written $(\dot{R}, \dddot{R}^{\frac{1}{3}})(\ddot{Si}, \dddot{Al}^{\frac{2}{3}})$.

The varieties proceeding from these isomorphous substitutions are many and diverse; and there are still others depending on the state of crystallization. The foliated and fibrous kinds early received separate names, and for a while were regarded as distinct species. Fibrous or columnar forms are very much less common than in hornblende, and lamellar or foliated kinds more common. The crystals are rarely long and slender, or bladed, like those of that species.

The name *Pyroxene* is from πῦρ, *fire*, and ξένος, *stranger*, and records Haüy's idea that the mineral was, as he expresses it, "a stranger in the domain of fire," whereas, in fact, it is, next to the feldspars, the most universal constituent of igneous rocks. This error, however, was more than counterbalanced by Haüy's discovery of the true crystallographic distinction of the species, which led him to bring together, under this one name, what Werner and others had regarded as distinct species. The name, therefore, is properly the name of the species, while *Augite* is only entitled to be used for one of its varieties.

The most prominent division of the species is into (A) the *non-aluminous*; (B) the *aluminous*. But the former of these groups shades imperceptibly into the latter.

These two groups are generally subdivided according to the prevalence of the magnesia, lime, protoxyd of iron, or protoxyd of manganese, or of two or three together of these protoxyd bases. Yet here, also, the gradation from one series to another is in general by almost insensible shades as to composition and chemical characters, as well as all physical qualities.

I. CONTAINING LITTLE OR NO ALUMINA.

1. *Lime-Magnesia Pyroxene*; MALACOLITE. (Basaltes spatosus, γ hwit., pt., *Cronstedt*, 68, 1758. Malacolit *Abildgaard* (Ann. Ch., xxxii. 1800); Delameth., J. de Phys., li. 249, 1800. Alalite, Mussite, *Bonvoisin*, ib., 409, May, 1806. Diopside (fr. Ala) *H.*, J. d. M., xx. 65, 1806 White Coccolite. Traversellit *Scheerer*, Pogg., xciii. 109, 1854.) Color white, yellowish, grayish-white to pale green. In crystals: cleavable and granular massive. Sometimes transparent and colorless. G.=3·2—3·38. Contains lime and magnesia, with less than 4 p. c. of protoxyd of iron. Formula, $(\dot{C}a, \dot{M}g)\ddot{Si}$. Anal. 1 corresponds to $(\frac{1}{3}\dot{C}a + \frac{2}{3}\dot{M}g)\ddot{Si}$; anal. 2–7 to $(\frac{1}{2}\dot{C}a + \frac{1}{2}\dot{M}g)\ddot{Si}$= Silica 55·7, magnesia 18·5, lime 25·8.

a. Malacolite, as originally used, included a bluish-gray, grayish-green, and whitish translucent variety from Sala, Sweden.

b. Alalite occurs in broad right-angled prisms, colorless to faint greenish or clear green, usually striated longitudinally, and came originally from Mt. Ciarmetta, in the Mussa Alp.

c. Traversellite, from Traversella, occurs in similar long glassy crystals, usually rectangular (planes *i-i*, *i-i*), much striated longitudinally, often clear green at one end and colorless at the other; cleavage parallel to *I*, perfect.

d. Mussite is white, grayish-white, and apple-green (according to Bonvoisin's original description), and occurs in prismatic implanted crystals, and also in masses made up of aggregated crystals, the obtuse prismatic edge rounded, and with cleavage parallel to the base. Named from the locality, the Mussa Alp (or elevated plane of the Mussa).

The optical characters of malacolite are as stated near top of the preceding page. Descloizeaux found the axial divergence in a crystal from Ala for the red rays as observed in the air, 111° 40′; for the yellow 111° 20′; and Heusser obtained for the same 112° 27′, 112° 12′.

e. *White Coccolite* is a granular variety. The original *coccolite* was green.

Named *Malacolite* from μαλακος, *soft*, because softer than feldspar, with which it was associated; and *Diopside* from δις, *twice* or *double*, and ὄψις, *appearance*.

2. *Lime-Magnesia-Iron Pyroxene;* SAHLITE. (Malacolit pt. *of authors.* Diopside pt. *H.*, l. c. Sahlit (fr. Sala) *d'Andrada*, Scherer's J., iv. 81, 1800; J. de Phys., li., 241, 1800. Baicalit (fr. L. Baikal) *Renovanz*, Crell's Ann., ii. 1793, 21; Baikalit *Karst.*, Tab. 34, 74, 1800. Funkite, Duf. Min., iii. 761, 1847. Coccolit *d'Andrada*, Scherer's J., iv. 1800. Protheite (fr. Zillerthal) *Ure.* Asbestus pt.) Color grayish-green to deep green and black; sometimes grayish and yellowish-white. In crystals; also cleavable and granular massive. G.=3·25—3·4. Named from Sala in Sweden, one of its localities, where the mineral occurs in masses of a grayish-green color, having a perfect cleavage parallel to the basal plane (*O*). Formula $(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{M}}\mathrm{g}, \dot{\mathrm{F}}\mathrm{e})\ddot{\mathrm{S}}\mathrm{i}$. In anal. 9, $\dot{\mathrm{C}}\mathrm{a} : \dot{\mathrm{M}}\mathrm{g} : \dot{\mathrm{F}}\mathrm{e}=2 : 1 : 2$; in 10, 11, this ratio=4 : 3 : 1, corresponding to Silica 53·7, magnesia 13·4, lime 24·9, prot. iron 8·0=100.

b. *Baikalite* is a dark dingy green variety, in crystals, cleavable like the preceding parallel to *O*. Named from Lake Baikal, in Siberia, near which it occurs.

c. *Protheite* is sombre-green, in crystals, and approaches fassaite; from Zillerthal in the Tyrol.

d. *Funkite* is dark olive-green coccolite from Boksäter in Gothland, having a larger percentage of $\dot{\mathrm{F}}\mathrm{e}$ than $\dot{\mathrm{M}}\mathrm{g}$. It may be convenient to use this name for the pyroxene here included that contains 10 p. c. or more of protoxyd of iron.

e. DIALLAGE. (Diallage pt. *H.*, Tr., 89, 1801. Hypersthene pt. Bronzite pt.) Part of the so-called *diallage*, or thin-foliated pyroxene, belongs here, and the rest under the corresponding division of the aluminous pyroxenes.

Color grayish-green to bright grass-green, and deep green; lustre of cleavage surface pearly, sometimes metalloidal or brassy; H.=4; G.=3·2—3·35. Double refraction strong; bisectrix negative; inclined about 38° to a normal to *i-i*, and showing therefore, when viewed through *i-i*, a single system of rings in the field of the polarizing instrument (Descl.); the angle 35° to 40°, observed in the air (24°—26° in oil) in the diallage of Knockdallian in Scotland, of Zobtenberg and Baumgarten in Silesia; a grayish hypersthene-like mineral in large folia in the gabbro of the Ruben coal mine near Neurode; the vanadiferous bronzite of Genoa. But the green diallage of Neurode, analyzed by v. Rath (No. 4, p. 219), has this angle about 49° 50′; and so also that of Bormio in Veltlin; diverging thus from ordinary diallage and diopside. With this variety belongs part also of what has been called *hypersthene* and *bronzite*—the part that is easily fusible. Common especially in serpentine rocks.

Named from διαλλαγή, *difference*, in allusion to the dissimilar cleavages.

The grass-green diallage-like mineral *smaragdite*, constituting, with saussurite, a rock, is in part, at least, amphibole (q. v).

3. *Iron-Lime Pyroxene;* HEDENBERGITE. (Hedenbergite (fr. Tunaberg) *Berz.*, Nouv. Syst. Min., 206, 269, 1819; Hedenberg, Afh., ii. 169. Lotalite (fr. Lotala) *Severgin*, before 1814. Bolopherit *Breith.*, Handb., 582, 1847.) Color black. In crystals, and also lamellar massive; cleavage easy parallel to *i-i*. G.=3·5—3·58. Contains lime and protoxyd of iron, with little or no magnesia; formula $(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{F}}\mathrm{e})\ddot{\mathrm{S}}\mathrm{i}$. Anal. correspond to $(\frac{1}{2}\dot{\mathrm{C}}\mathrm{a}+\frac{1}{2}\dot{\mathrm{F}}\mathrm{e})\ddot{\mathrm{S}}\mathrm{i}$. Named after the Swedish chemist, Ludwig Hedenberg, who first analyzed and described the mineral. *Lotalite*, from Lotala in Finland, is in black lamellar masses. Beudant gives for the angles of hedenbergite *O* ∧ *I*=100° 10′—12′, *I* ∧ *I*=87° 15′; and Breithaupt for the Taberg mineral (*Pyroxenus diagonalis* Breith.) *I* ∧ *I* =87° 28′, *C*=73° 51′.

4. *Lime-Magnesia-Manganese Pyroxene;* SCHEFFERITE (Schefferit *J. A. Michaelson*, J. pr. Ch., xc. 107). Color reddish-brown. G.=3·39. Contains lime, magnesia, and protoxyd of manganese, and in the absence of zinc differs from jeffersonite. Formula $(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{M}}\mathrm{g}, \dot{\mathrm{M}}\mathrm{n})\ddot{\mathrm{S}}\mathrm{i}$; from Longban.

The Richterite of Breith. (B. H. Ztg., xxiv. 364, 1865) is near schefferite in composition. It occurs in acicular crystals, having *I* ∧ *I*=133° 38′, which appears to be the angle *I* ∧ *i-i* of pyroxene (=133° 33′), with G.=2·826; color isabella-yellow, rarely pale yellowish-brown, and is easily fusible. If the prismatic angle is *I* ∧ *i-i* of pyroxene, the mineral belongs here. But Igelström finds a very similar mineral in aspect and composition at Paisberg, with *I* ∧ *I*=124°; and the analyses are given under amphibole (see p. 234).

5. *Lime-Iron-Manganese Pyroxene.* A variety from L. Laach, analyzed by Bischof, is here included.

6. *Lime-Iron-Manganese-Zinc Pyroxene;* JEFFERSONITE (*Keating & Vanuxem*, J. Ac. Philad., ii. 194, 1822). Color greenish-black. Crystals often very large (3–4 in. thick), with the angles generally rounded, and the faces uneven, as if corroded. G.=3·36. Contains lime, magnesia, protoxyd of

iron, and protoxyd of manganese, with oxyd of zinc; formula $(\dot{C}a, \dot{F}e, \dot{M}g, \dot{M}n, \dot{Z}n)\ddot{S}i$. Named after Mr. Jefferson.

II. ALUMINOUS.

7. *Aluminous Lime-Magnesia Pyroxene;* LEUCAUGITE (*Dana*). Color white or grayish. Contains alumina, with lime and magnesia, and little or no iron; formula $(\dot{C}a, \dot{M}g)(\ddot{S}i, \bar{A}l^{\frac{2}{3}})$. Looks like diopside. H.=6·5; G.=3·19, Hunt. Named from λευκος, *white*.

8. *Aluminous Lime-Magnesia-Iron Pyroxene;* FASSAITE, AUGITE. (For syn. of *Augite*, see p. 212. Also: Basaltische Hornblende pt. *Wern.*, Bergm. J., 1792; Basaltine *Kirw.*, Min., i. 219, 1794. Fassait *Wern.*, Hoffm. Min., iv. 2, 110, 1817. [Not Fassaite *Dolomieu*, which was a zeolite.] Macluréite *Nuttal*, Am. J. Sci., v. 246, 1822=Amphibole *H. Seybert*, J. Ac. Philad., ii. 139, 1821. Pyrgom *Breith.*, Char., 140, 1832.) Color clear deep-green to greenish-black and black; in crystals, and also massive; subtranslucent to opaque; G.=3·25—3·5. Optical characters as for malacolite. Contain protoxyd of iron, with lime and magnesia; general formula $(\dot{C}a, \dot{M}g, \dot{F}e)(\ddot{S}i, \bar{A}l^{\frac{2}{3}})$.

a. Fassaite (or *Pyrgom*). Includes the green kinds found in metamorphic rocks. Named from the locality at Fassa in the Tyrol, which affords deep-green crystals, sometimes pistachio-green, like the epidote of the locality. *Pyrgom* was so named from πύργωμα, *a tower*.

b. Augite. Includes the greenish or brownish-black and black kinds, occurring mostly in eruptive rocks, but also in metamorphic. Named from αὐγή, *lustre*.

The *Augite* of Werner (and Volcanite *Delameth.*) included only the black mineral of igneous rocks—the *volcanic schorl* of earlier authors.

c. Aluminous Diallage.

9. *Aluminous Iron-Lime Pyroxene;* HUDSONITE (*Beck*, Min. N. Y., 405, 1842). Lamellar or cleavable massive. Color black. Streak green. Often has a bronze tarnish. G.=3·5, Beck; 3·43—3·46, Brewer. Contains lime and protoxyd of iron, with but little magnesia; formula $(\dot{C}a, \dot{F}e)(\ddot{S}i, \bar{A}l^{\frac{2}{3}})$. Named from the Hudson river, in the vicinity of which it occurs, in Cornwall, Orange Co., N. Y.

b. Polylite of Thomson (Min., i. 495, 1836) may be the same compound. It is described as cleavable massive; G.=3·231; H.=6—6·5; color black; opaque; and is stated to come from a bed of magnetic iron ore at Hoboken, N. J., where no such bed of ore exists.

Appendix.—10. ASBESTUS. Asbestus is a finely fibrous variety, with the fibres easily separable and usually flexible. But most asbestus belongs to the species *hornblende*, which tends more to run into fibrous forms.

It is difficult to distinguish the hornblende asbestus from the pyroxene, except by noting its association with known varieties of one or the other species; and this method is not free from doubt. See further under HORNBLENDE for description, analyses, and localities of asbestus.

11. *Breislakite* (*Brocchi*, Cat. di una raccolta di Rocce, 28, 60, 70, 192, 1817; *Cyclopeite*, in Descl. Min., 65, 1862). Occurs in wool-like forms at Vesuvius and Capo-di-Bove. Its crystallographic identity with pyroxene has been shown by Chapman (Phil. Mag., xxxvii. 444, 1850). The particular variety of pyroxene to which it belongs has not been ascertained, as no analysis of it has been made. Named after Breislak, an Italian geologist.

12. *Lawrofite* (Lawrowit, Vanadin-Augit, Kokscharof, Bull. Ac. St. Pet., xi. 78, 1866) is an alumina pyroxene, colored green by vanadium, from the river Sludianka, beyond Lake Baikal, where it occurs coarse granular massive with quartz, and also in small imperfect crystals. Cleavage affords the prism 87° 7′; and there is the usual lamination from compound structure parallel to *O*. The color is fine emerald-green. It contains besides silica some alumina, iron, lime, magnesia, and a trace of manganese and vanadium; but no analysis has been made, so that its exact place among the pyroxenes is not certain.

I. CONTAINING LITTLE OR NO ALUMINA.

1. *Lime-Magnesia Pyroxene; Malacolite.* Analyses: 1, Nordenskiöld (Schw. J., xxxi. 457); 2, H. Rose (ib., xxxv. 86); 3, T. Wachtmeister (ib., xxx. 334); 4, Hermann (J. pr. Ch., xxxvii. 190); 5, H. No. 1, fr. gabbro, G.=3·249; 2, ib., G.=3·244; 3, ib., G.=3·245; 4, ib., G.=3·336; 5, fr. hypersthene rock, G.=3·343; 6, G.=3·21, H.=4·5; 7, fr. gabbro of Graubündten, G.=3·253; 8, met. diallage, G.=3·261; 9. met. diallage, fr. serpentine; 10, fr. gabbro, G.=3·256; 12, fr. gabbro, G.=3·23; 13, fr. gabbro, G.=3·300; 14, G.=3·23; 15, G.=3·2; 16, fr. gabbro; 18, vanadiferous bronzite, G.=3·25; 19, 20, fr. gabbro, pseudo-hypersthene; 21, pseudo-hypersthene, assoc. with quartz, G.=3·25; B.B. fus.

Pyr., etc.—Varying widely, owing to the wide variations in composition in the different varieties, and often by insensible gradations. Fusibility, from the almost infusible diallage to 3·75 in diopside; 3·5 in sahlite, baikalite, and omphacite; 3 in jeffersonite and augite; 2·5 in hedenbergite. Varieties rich in iron afford a magnetic globule when fused on charcoal, and in general their fusibility varies with the amount of iron. Jeffersonite gives with soda on charcoal a reaction for zinc and manganese; many others also give with the fluxes reactions for manganese. Most varieties are unacted upon by acids.

Obs.—Pyroxene is a common mineral in crystalline limestone and dolomite, in serpentine, and in volcanic rocks; and occurs also, but less abundantly, in connection with granitic rocks and metamorphic schists. The pyroxene of limestone is mostly the white and light green, or gray varieties; that of most other metamorphic rocks, sometimes white or colorless, but usually green of different shades, from pale green to greenish-black, and occasionally black; that of serpentine is sometimes in fine crystals, but often of the foliated green kind called *diallage*; that of eruptive rocks is the black to greenish-black *augite*.

In limestone the associates are often hornblende, scapolite, garnet, orthoclase, sphene, phlogopite, and sometimes brown tourmaline, chlorite, talc, zircon, spinel, rutile, etc.; and in other metamorphic rocks mostly the same. In eruptive rocks the crystals are imbedded, and often occur with similarly disseminated chrysolite, crystals of orthoclase, sanidin, labradorite, leucite, etc.

Pyroxene is an essential constituent of many rocks. *Pyroxenyte* is a metamorphic rock consisting mainly of compact pyroxene of the Sahlite section. *Lherzolyte*, from the borders of Lake Lherz, in the department of Ariége in France (described by Charpentier and Dufrénoy as a variety of pyroxene), is a green pyroxenic rock. (For constitution, see under SPINEL.) Pyroxene along with labradorite constitutes the dark gray and green to black eruptive rock called *doleryte*, which often contains also magnetic iron ore in grains; and with labradorite and chrysolite, the related rock *basalt*. *Doleritic* and *basaltic lavas* have the same composition. With leucite it forms the *leucitophyr*, the common igneous rock of Vesuvius; and with nephelin, *nephelinyte* or *nephelin-doleryte*, another Italian igneous rock. The pyroxene of these igneous rocks is the black variety *augite;* and it often occurs in distinct crystals of the forms in figs. 203–206. Many kinds of *tufa*, and the earthy basaltic rock called *wacke* (either a variety of tufa or a decomposed basalt or doleryte) often consist largely of crystals or grains of augite.

Diallage occurs generally in serpentine or steatitic rocks.

Many foreign localities of pyroxene have already been briefly indicated (pp. 214–219). The crystals of Ala in Piedmont are associated with garnets and talc in veins traversing serpentine; and the more transparent are sometimes cut and worn as gems.

In N. America, it occurs in *Maine*, at Raymond and Rumford, diopside, sahlite, etc.; at Deer Isle, diallage in serpentine. In *Vermont*, at Thetford, black augite, with chrysolite, in boulders of basalt. In *Mass.*, in Berkshire, white crystals abundant; at the Bolton quarries, same, good; Westfield and Blanford, diallage in serp. In *Conn.*, at Canaan, white cryst. 2–3 in. long by 1–1 in. broad, in dolomite; in Trumbull, large green cryst. in limestone; in Reading, on the turnpike near the line of Danbury, small transp. cryst., and granular; at Watertown, near the Naugatuck, white diopside. In *N. York*, in N. Y. Co., white cryst. in dolomite; at Warwick, fine cryst. (descr. and fig. by v. Rath, Pogg., cxi. 263); in Westchester Co., white, at the Sing-Sing quarries; in Orange Co., in Monroe, at Two Ponds, cryst., often large, with scapolite, sphene, etc., in limestone; 3 m. S.E. of Greenwood furnace, sahlite with coccolite; ½ m. E. of same, in cryst. with mica in limestone, one 6 in. long and 10 in. in circ.; 1 m. W. of Coffee's Hotel in Monroe, black coccolite; 2½ m. N. of Edenville, gray cryst.; 1 m. N.W. of Edenville, black cryst. in limestone; in Cornwall, the var. *hudsonite;* near Amity and Fort Montgomery, good; in Forest-of-Dean, lamellar, green, and bronze-colored, with black coccolite; in Putnam Co., near Patterson, grayish-white cryst., abundant; at Rogers' Rock, L. George, massive and granular (coccolite), gray, green, brown; near Oxbow, on Vrooman Lake; in Lewis Co., at Diana, white and black cryst.; in St. Lawrence Co., at Fine, in large cryst.; in Essex Co., near Long Pond, cryst. (f. 213), also beautiful green coccolite; at Willsboro', green coccolite with sphene and wollastonite. In *N. Jersey*, in Franklin, good cryst. In *Penn.*, near Attleboro', cryst. and granular; in Pennsbury, at Burnett's quarry, diopside. In *Maryland*, Hartford Co., at Cooptown, diallage. In *Delaware*, at Wilmington, a hypersthene-like variety (anal. 21), Nuttal's *Maclureite*. In *Canada*, at Bytown, subtrp. white cryst., 1–1½ in., in limestone; at Calumet I., grayish-green cryst. in limestone with phlogopite, some appearing to be altered *Eozoon;* at the High Falls of the Madawaska, cryst. sometimes 1 ft. long and 4 in. wide, having cryst. of hornblende attached; in Kildau, as a rock; in Bathurst, colorless or white cryst.; near Ottawa, in large subtrp. cryst., in limestone; at Grenville, dark green cryst., and granular; at Montreal, Rougemont and Montarvelli Mts., black in doleryte.

Alt.—Pyroxene undergoes alteration in different ways, as has been well explained by Bischof, and many species have been instituted on the material in different stages of change. In the simplest, there is only a taking up of water, producing a "hydrous augite." The water found in several of the analyses already cited may be from this source. In many cases a loss of silica appears to attend this hydration; and often, also, a loss of one or more of the bases (of which the lime and iron are the first to go), through the dissolving agency of waters holding carbonic acid, or carbonates, in solution. Thus may come the following substances:

13. HYDROUS AUGITE. Analyses 1, 2, 3 of an altered sahlite from Sala, Sweden, the three analyses made on different fragments of the same piece, by H. Rose.

14. PICROPHYLL (Svanberg, Pogg., l. 662, 1839). Also from Sala, where it occurs both massive, with the cleavage of pyroxene, and fibrous, of a greenish-gray color, with H.=2·5 and G.=2·75 Analyses: 4, Svanberg (l. c.). Formula deduced $\dot{R}\,\ddot{Si}+\frac{1}{3}\dot{H}$. Named from πικρος, *bitter*, and φυλλον, *leaf*, in allusion to the odor when moistened.

15. PYRALLOLITE (*Nordenskiöld*, Schw. J., xxxi. 389, 1820). From Finland, where it occurs mostly in limestone, with pyroxene and scapolite. A pyrallolite from Sibbo in Finland has been named *Vargasite*, after Count Vargas, Huot Min., ii. 676, 1841; Wargasit *Germ.* Analyses: 5, Nordenskiöld (l. c.), of the original mineral from Storgord, whitish or greenish-white, with H.=3·5–4, G.=2·53–2·78, for which the formula $\dot{Mg}\,\ddot{Si}+\frac{1}{3}\dot{H}$ has been written; 6–14, later

by Arppe, Furuhjelm, Runeberg, and Selin (Anal. Finsk. Min., 35), from different Finland localities—6, large whitish crystals from Storgard, G.=2·53; 7–10, from Kulla quarry in Kimito; 8, whitish, augitic in structure, H.=3—4; 9 and 10, whitish and earthy; 11, green and columnar, G.=2·70, H.=3—4, from Takvedaholm; 12, similar, from Skräbböle; 13, greenish and granular, with G.=2·61, from Haapakyla; 14, brownish or grayish-yellow and columnar, H.=3, G.=2·66, from Frugard. The crystalline structure is that of pyroxene. Named from πῦρ, *fire*, ἄλλος, *other*.

16. SCHILLER SPAR in part (Schillerstein *Wern.*, *Bastite* pt.) An impure serpentine, from Baste in the Harz, having often the cleavage and forms of pyroxene; H.=3·5—4; G.=2·5—2·76; lustre metallic-pearly to subvitreous; color dark-green to pinchbeck-brown. Analysis 15, by Köhler (Pogg., xi. 192); 16, Rammelsberg (Pogg., xlix. 387). See further SERPENTINE.

17. TRAVERSELLITE (*Scheerer*, Pogg., xciii. 109, 1854). A leek-green mineral, in crystals, having the form of pyroxene, from Traversella in Piedmont. Analysis: 17, R. Richter (l. c.).

18. PITKARANDITE (*Scheerer*, Pogg., xciii. 100, 1854). Has a leek-green or dark-green color, and looks like unaltered pyroxene, having the crystal planes *I*, *i-i*, *i-i*, with cleavage parallel to *i-i*. It is from Pitkäranda in Finland. Analyses: 18, R. Richter (Pogg., xciii. 101); 19, Frankenhauser. Scheerer refers here part of pyrallolite (anal. 20).

19. STRAKONITZITE (*v. Zepharovich*, Jahrb. geol. Reichs., iv. 695, 1853). Approaches steatite. It occurs in greenish-yellow crystals, soft and greasy in feel, with G.=1·91. Analysis: 21, v. Hauer (l. c.).

20. MONRADITE (*Erdmann*, Ac. H. Stockh., 1842, p. 108). Probably a slightly altered pyroxene or hornblende. Described as occurring granular massive, with two unequal cleavages mutually inclined about 130°; with H.=6, G.=3·2678; color yellowish, honey-yellow, and lustre vitreous. Analysis: 22, Erdmann (l. c.). Formula deduced $(\mathrm{Mg}, \dot{\mathrm{Fe}})\ddot{\mathrm{Si}}+\frac{1}{2}\dot{\mathrm{H}}$. From Bergen in Norway Named after Dr. Monrad.

T. S. Hunt has analyzed some altered pyroxenes (Logan's Rep., 1863, 490) from Canada, related closely in composition to his loganite (which is altered hornblende; see under HORNBLENDE); and also

21. HYDROUS DIALLAGES (l. c., p. 469), that may be examples of other alterations of the species. The following are his analyses: No. 1, of a brittle cleavable-massive mineral, forming a bed in a deposit of apatite in North Elmsley, having the cleavages of pyroxene perfect; H.=3; G.=2·538—2·539: color greenish-gray; powder unctuous. No. 2, a similar material from N. Burgess, having the cleavage of pyroxene; a waxy lustre; H.=2—3, and G.=2·32—2·35; pale grayish-green color; an unctuous feel. No. 3, a coarse, cleavable, bronze-colored diallage, forming a rock at Ham. No. 4, a rock from Orford, consisting of small masses of pearly, translucent, celandine-green diallage, with H.=5·0, and G.=3·02—3·03:

		$\ddot{\mathrm{Si}}$	$\overline{\overline{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$

A complete removal of the lime and iron produces *steatite* or *talc*, a common material of pseudomorphs. *Rensselaerite* is a variety of steatite (see TALC), having sometimes the cleavage of pyroxene. Pyrallolite is also in part talc or steatite (anal. 5, 13, 14). *Saponite* and *serpentine* (q. v.) are other results of the same kind of alteration. they consisting, like talc, of silica, magnesia, and water. *Hortonite* is a steatitic pseudomorph of pyroxene, found in Orange Co., N. Y., with chondrodite.

The following are other kinds of pseudomorphs: Hematite, Limonite, Magnetite, Palagonite (which see). In the pyroxenes containing much iron, especially the augitic varieties, the protoxyd of iron, when moisture and air are present, may pass to a higher state of oxydation, and the mineral take a *red* color (the color of anhydrous sesquioxyd of iron (*hematite*), or it may take up water as well as oxygen, and become of a *brownish-yellow* color, the color of the hydrous sesquioxyd, or *limonite*. *Magnetite* is another result, and probably through the alteration of one of these oxyds as an intermediate state.

Palagonite, as Bunsen has observed, is one of the products arising in part from the change of the iron to a sesquioxyd; it is the material of many tufas of volcanic regions, as those of Iceland and Etna, such tufas having been made from doleritic or basaltic lavas abounding in pyroxene. Bunsen remarks that palagonite may be made artificially by putting powdered basalt into a large excess of caustic potash in fusion and pouring on water; the product, after washing, is hydrated, pulverulent, and gelatinizes with weak acids, and its composition is like that of the purest palagonite of Iceland. For analyses, see p. 488.

Epidote is another mineral resulting from the kind of change here mentioned.

In one variety of the diallage from the gabbro of Harzburg (see analyses of others on p. 219), A. Streng found (B. H. Ztg., xxiii. 54) $\ddot{\mathrm{Si}}$ 45·73, $\dddot{\bar{\mathrm{Al}}}$ 5·60, $\dddot{\bar{\mathrm{Fe}}}$ 12·18, $\dot{\mathrm{Fe}}$ 8·00, $\dot{\mathrm{Mg}}$ 12·55, $\dot{\mathrm{Ca}}$ 8·86, alkalies 0·55, $\dot{\bar{\mathrm{H}}}$ 4·68=98·15—a percentage of oxyd of iron and of water which indicates partial alteration.

Cimolite. In the case of the aluminous pyroxene, when all the bases except the alumina are removed and water taken up, there may result *cimolite* (q. v.), a whitish clay-like earth, which has been observed constituting pseudomorphs of augite at Bilin in Bohemia. In the change to this aluminous silicate, alumina may possibly be added, to some extent, from an external source, as from feldspar decomposing in the same rock. Pisani gives the following composition of a greenish aluminous, although talc-like, pseudomorph having the angles of pyroxene (C. R., liv. 51):

$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\bar{\mathrm{H}}}$
56·52	20·49	2·67	5·94	0·93	3·32	3·88	7·40

Glauconite. Mica. Under the action of alkaline waters, alkalies may be introduced. Thus the hydrous mineral *glauconite* (q. v.) or *green earth* may result as a constituent of some augite pseudomorphs; or the essentially anhydrous mineral *mica*, which has been observed by Kjerulf as a pseudomorph after augite, in the Eiffel. Kjerulf gives the following analyses (1) of an unaltered augite, and (2) the mica derived from it:

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	Ign.
1. *Augite*	50·21	6·94	7·59	13·66	19·85	—	—	0·33=98·58
2. *Mica pseud.*	43·10	15·05	23·25	10·82	0·81	0·82	4·62	1·50, with $\ddot{\mathrm{Ti}}$ 1·03 as impurity.

Acmite (q. v.) is considered by Bischof and Rose a pyroxene altered by the alkaline process.

Quartz. Opal. Calcite. The removal of the mineral by the decomposing and dissolving agencies may be attended by the introduction of silica from the waters present, these waters having become siliceous as a consequence of the decompositions. Hence may come siliceous pseudomorphs, either anhydrous like *quartz*, or hydrous like *opal*. One such from Vesuvius is described by Rammelsberg, which still contained some part of the bases, affording him on analysis (Pogg., lixx. 387):

$\ddot{\mathrm{Si}}$ 85·31, $\dddot{\bar{\mathrm{Al}}}$ 1·58, $\dddot{\bar{\mathrm{Fe}}}$ 1·67, $\dot{\mathrm{Mg}}$ 1·70, $\dot{\mathrm{Ca}}$ 2·66, $\dot{\bar{\mathrm{H}}}$ 5·47=98·42.

In some cases the waters hold in solution carbonate of lime instead of silica, and this salt of lime consequently takes the place of the removed mineral, and so *calcite* pseudomorphs after pyroxene are produced.

22. URALITE. Augite also occurs altered to *hornblende*, and the product has been named *uralite* by Rose (Pogg., xx. 322, 1830, xxvii. 97, xxxi. 619). The crystals have the form of augite, but the cleavage of hornblende. $I \wedge I = 124°$; they appear to consist of an aggregation of minute hornblende prisms. They are subtransparent in very thin laminæ, have a deep-green color, a greenish-white streak, with H.=5 or nearly, and G.=3·14—3·15, Ural; 3·273, Silesia, v. Rath. Analyses: 1, Kudernatsch (Pogg., xxxvii. 586); 2, Rammelsberg (Min. Chem., 490); 3, G. v. Rath (Pogg., xcv 557):

	S̈i	A̶l	Ḟe	Ṁn	Ṁg	Ċa	Ḣ
1. Ural	53·05	4·56	16·37	*tr.*	12·90	12·47	——=99 35 Kudur.
2. "	50·75	5·65	16·48	0·79	12·28	11·59	1·80=99·34 Ramm.
3. Silesia	48·70	0·82	25·21	——	12·01	11·25	1·01, alk. *tr.*=99 Rath.

Uralite was obtained by Rose from a green porphyritic rock at Mostovaja, Lake Baltym, near Katharinenberg, and at Carminskoj, near Miask, in the Ural. It has since been reported from Arendal in Norway; Tavignolo, near Predazzo in the Tyrol; near Neurode in Silesia, in greenstone; Tunguragua in Quito; Mysore in India.

Artif.—Diopside has been observed as a furnace product at the iron-works of Philipsburg, N. Jersey (G. J. Brush, Am. J. Sci., II. xxxix. 132); and dark-colored pyroxene at Gaspenberg; in an old furnace near Hacheburg; a copper furnace near Dillenburg; at Fahlun and Oldbury; a manganese-augite at Mägdesprung.

Formed in crystals, as diopside, artificially by the action of chlorid of silicon on magnesia (*Daubrée*); also, a grayish-white var., by mixing the constituents and exposing to a high heat (Berthier).

Augite in small yellow crystals has been found in old fumaroles at Eiterkopfe, near Andernach (v. Rath).

238A. OMPHACITE. (Omphazit [fr. Baireut] *Wern.*, Hoffm. Min., ii. 2, 302, 1812; *Breith.*, ib., iv. 2, 125, 1817, Handb., 612, 1841, B. H. Ztg., xxiv. 365, 397, 1865.)

Monoclinic. Cleavage: in two directions with the interangle 115°, one perfect, the other imperfect. Massive, granular, disseminated. H.=5—6. G.=3·2—3·3; 3·178—3 231, Breith.; 3·263, fr. Ober-Pferdt, 3·270. fr. between Wustuben and Weppenreuth, 3·248, fr. Silberbach, 3·301, fr. Stambach, all in the Fichtelgebirge, Fikenscher. Lustre vitreous. Color grass- to leek-green.

Comp.—Analyses by J. Fikenscher (B. H. Ztg., xxiv. 397):

	S̈i	A̶l	Ḟe	Ṁg	Ċa	Ṅa	K̇	ign.
1. Ober-Pferdt	52·57	9·12	5·32	13·75	17·41	1·11	0·28	0·32=99·98
2. Wustuben	52·85	9·69	4·08	12·85	18·05	1·73	0·32	0·62=99·69
3. Silberbach	52·77	9·19	4·81	13·60	18·11	1·22	——	0·41=100·11
4. Stumbach	52·16	8·71	11·63	10·77	14·16	0·87	0·14	0·50=99·94
5. Pacher, Styria	50·29	6·67	3·26	15·22	21·50	0·88	0·88	0·45, C̈r 2·07=100·64

Anal. 1 gives for the O ratio of Ṙ, R̶, S̈i, 2·6 : 1 : 6·1; No. 2, 2·8 : 1 : 6·4; No. 5, 13·3 : 3·75 : 26·15 (differing much from those adopted by Fikenscher). Although much care was taken to use the pure mineral, the results seem to indicate an intimate mixture with some alumina silicate; and possibly with lime-garnet or kyanite, which are its associates. If this be the case, the mineral may still be pyroxene or hornblende, as has been supposed. After an examination of the mineral, we regard with doubt the cleavage angle given by Breithaupt.

Omphacite occurs near Hof in Baireut, Bavaria, at the localities mentioned above, and also at Pacher in Styria. It is intimately mixed with a lime-garnet, and also usually with kyanite, making the tough greenish rock, spotted with pale garnet, called *eclogyte*. The rock contains often scales of a silvery mica. The name *Omphacite* is from ὄμφαξ, *an unripe grape*, alluding to the color; it is among the names of green stones mentioned by Pliny.

238B. VIOLAN Breithaupt (J. pr. Ch., xv. 321, 1838). Occasionally in prismatic crystals, affording, according to Descloizeaux, the angles, and the planes *I*, *i-i*, *i-ì*, and *i-8*, of pyroxene, and cleavage in the direction of *I*. Usually lamellar massive, sometimes fibrous. H.=6. G.=3·233. Lustre waxy. Color dark violet-blue. Translucent, but in thin plates transparent.

Damour obtained (Descloizeaux's Min., i. 66), in an unsatisfactory analysis of the lamellar mineral (unsatisfactory because this variety is penetrated by a fibrous mineral which appears to be tremolite), S̈i 56·11, A̶l 9·04, Ḟe 2·46, Ṁn 2·54 Ṁg 10·40, Ċa 13·62, Ṅa 5·63,=99·80. Plattner had previously ascertained by his trials (J. pr. Ch., xv. 321) that it was a silicate of alumina, iron, manganese, lime, magnesia, and soda.

It is unaltered in the closed tube. B.B. fuses easily to a clear glass, coloring the flame yellow (soda). With borax and soda gives reactions for manganese and iron.

Occurs in small seams with white quartz, white fibrous tremolite spotted violet with manganese greenovite and manganesian epidote, in the braunite of St. Marcel, in the valley of Aosta, Piedmont. Named from its color.

239. ÆGIRITE. *Ægirin Esmark*, Berzelius, Jahrb. Min., 1835, 184.

Monoclinic, and isomorphous with pyroxene. Cleavage: *i-i* perfect; *I* less so; *i-ì* still less. Usual in striated or channelled prisms.

H.=5·5–6. G.=3·45—3·58; 3·578, fr. Skaadöe, Rammelsberg; 3·464 fr. Berkevig, Pisani. Lustre vitreous. Color greenish-black. Streak dark green. Subtranslucent to opaque.

Comp.—$\dot{R}^3\ddot{Si}^3+\ddot{\bar{F}}e\,\ddot{Si}^3=(\frac{1}{2}\dot{R}^3+\frac{1}{2}\ddot{\bar{F}}e)\ddot{Si}^3$=, if $\dot{R}=\dot{C}a+\dot{N}a+\dot{F}e$, Silica 50·7, sesquioxyd of iron 22·6, protoxyd of iron 10·1, lime 7·9, soda 8·7=100. Analyses: 1, Rammelsberg (Pogg., ciii. 286, 302); 2, Pisani (C. R., lvi. 846):

	$\ddot{Si}$	$\ddot{\bar{A}}l$	$\ddot{\bar{F}}e$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$
1. Skaadöe	50·52	1·22	22·07	8·80	1·40	1·28	5·97	9·29	0·94=100·72 Ramm.
2. Berkevig	52·11	2·47	22·80	8·40	——	0·41	2·60	12·10, $\dot{H}$ 0·80=101·19 Pisani.	

For an imperfect anal by Plantamour, see Bibl. Univ. Genève, 1841.

As Rammelsberg observes, ægirine holds the same relation in composition to pyroxene that arfvedsonite does to hornblende: in each alkalies being present, and sesquioxyd of iron replacing to a large extent the protoxyd bases.

Pyr., etc.—B.B. fuses easily, coloring the flame yellow (soda); gives a magnetic globule on charcoal. Not appreciably attacked by acids.

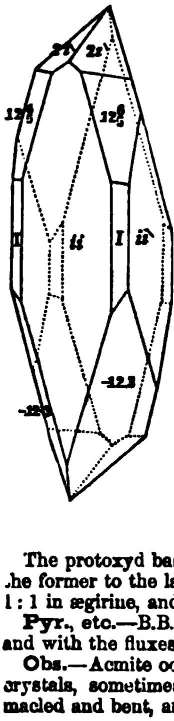
Obs.—Occurs with leucophanite, cancrinite, elæolite, in Norway, near Brevig, on the Isle of Skaadöe, and at Berkevig: Hot Springs, Arkansas.

Von Hornberg obtained from a perfect crystal from Lamöe, *I* ∧ *I*=87° 21′—87° 47′, and 92° 48—92° 20′, the variation owing to a slight irregularity in the prism, the edges and faces being not quite parallel.

Named after Ægir, the Scandinavian god of the sea.

240. ACMITE. Achmit *Ström*, Ak. H. Stockh., 1821, 160, and *Berz.*, ib., 163. Akmit *Germ.*

215



Monoclinic. *C*=74°, *I* ∧ *I*=86° 56′; *a* : *b* : *c*=0·5405 : 1 : 0·9135. Occurring planes: *O*; vertical, *i-i*, *i-ì*, *I*: dome, 2-*ì*; pyramidal, 4-2, —12-3, 12-$\frac{8}{5}$. 4-2 replaces the edge between 2-*ì* and *i-i*. Cleavage: *I* distinct; *i-ì* less so Plane *i-i* often longitudinally striated or channelled. Twins: composition-face *i-i*; common.

H.=6. G.=3·2—3·53; 3·43, Rammelsberg, piece of a crystal; 3·53, same pulverized. Lustre vitreous, inclining to resinous. Streak pale yellowish-gray. Color brownish or reddish-brown; in the fracture blackish-green. Opaque. Fracture uneven—earthy. Brittle. Plane of optical axis parallel to clinodiagonal section, Descl.

Comp.—$\dot{R}^3\ddot{Si}^3+2\ddot{\bar{F}}e\,\ddot{Si}^3=(\frac{1}{3}\dot{R}^3+\frac{2}{3}\ddot{\bar{F}}e)\ddot{Si}^3$=, if $\dot{N}a:\dot{F}e=3:1$, Silica 51·3, sesquioxyd of iron 30·4, protoxyd of iron 5·1, soda 13·2. Analyses: 1. Berzelius (Ak. H. Stockh., 1821, 160); 2, Lehunt (Thomson's Min., i. 480); 3, Rammelsberg (Pogg., ciii. 300):

	$\ddot{Si}$	$\ddot{\bar{F}}e$	$\ddot{\bar{M}}n$	$\dot{F}e$	$\dot{M}n$	$\dot{C}a$	$\dot{N}a$
1. Rundemyr	55·25	31·25	1·08	——	——	0·72	10·40, $\ddot{Ti}$ *tr.*=98·70 B.
2. "	52·02	——	——	28·08	3·49	0·88	13·33, $\dot{M}g$ 0·50, $\ddot{\bar{A}}l$ 0·68=98·98 L.
3. "	51·66	28·28	——	5·23	0·69	——	12·46, $\dot{K}$ 0·48, $\ddot{Ti}$ 1·11, ign. 0·39=100·25 R.

The protoxyd bases are mainly soda and protoxyd of iron. Rammelsberg makes the ratio of the former to the latter 3 : 1. The ratio of the protoxyds to the sesquioxyds is 1 : 2, while it is 1 : 1 in ægirine, and 1 : 4 in spodumene. Anal. 1 gives the O. ratio for bases and silica=1 : 2½.

Pyr., etc.—B.B. fuses at 2 to a lustrous black magnetic globule, coloring the flame deep yellow, and with the fluxes reacts for iron and sometimes manganese. Slightly acted upon by acids.

Obs.—Acmite occurs at Rundemyr, 4 m. S. of Dunserud, near Kongsberg in Norway, in slender crystals, sometimes nearly a foot long, imbedded in feldspar and quartz; the crystals are often macled and bent, and quite fragile.

Named from 'ακμή, *a point*, in allusion to the pointed extremities of the crystals.

G. Rose has suggested that acmite, as hitherto observed, is probably in a somewhat altered condition, and that possibly the ægirine of Brevig is acmite in an unchanged state (Kryst. Ch Min., 76, 1852).

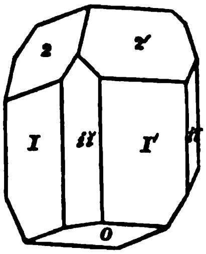
$I\wedge 2'$	86 35	85 24	

216



Cleavage: *I* perfect; *O* less perfect. Usually massive.

H.=5·5–6·5. G.=3·4–3·68; 3·612, Longban; 3·634, Siberia; 3·63 Stirling, Hermann. Lustre vitreous. Color light brownish-red, flesh-red, sometimes greenish or yellowish, when impure; often black outside from exposure. Streak white. Transparent—opaque. Fracture conchoidal—uneven. Very tough when massive.

Comp., Var.—Silicate of manganese, $\dot{M}n\,\ddot{S}i$=Silica 45·9, prot. manganese 54·1=100. Usually some $\dot{F}e$ and $\dot{C}a$, and occasionally $\dot{Z}n$, replaces part of the $\dot{M}n$.

1. *Ordinary.* (*a*) Crystallized. Either in crystals or foliated. The ore in crystals from Paisberg, Sweden, was named *Paisbergite* under the idea that it was a distinct species. (*b*) Granular massive.

2. *Calciferous;* BUSTAMITE. Contains 9 to 15 p. c. of lime replacing part of the $\dot{M}n$. Often also impure from the presence of carbonate of lime, which suggests that part of the lime replacing the $\dot{M}n$ may have come from partial alteration. Grayish-red. Named after Mr. Bustamente, the discoverer.

3. *Zinciferous;* FOWLERITE. In crystals and foliated, the latter looking much like cleavable red feldspar; the crystals sometimes half an inch to an inch through. $I\wedge I$=86° 30′, Torrey. G.=3·34, Breith.; 3·44, Thomson. This mineral is mentioned by Fowler in Am. J. Sci., ix. 245, 1825 as *Siliceous oxyd of manganese* from Sterling, N. J., and as often containing dysluite (zinciferous spinel). It occurs under the same name in Robinson's Cat. Amer. Min., 298, 1825. It is Thomson's *ferro-silicate of manganese*, Ann. Lyc., N. Y., iii. 28, 1828.

Analyses: 1, Berzelius (Afhandl., i. 110, iv. 382); 2, 3, Ebelmen (Ann. d. M., IV. vii. 8); 4, Hermann (J. pr. Ch., xlvii. 6); 5, A. Schlieper (This Min., 463, 1850); 6, Igelström (J. pr. Ch., liv 190); 7, H. Hahn (B. H. Ztg., xx. 267); 8, Dumas (Ann. Sci. Nat., viii. 411); 9, Ebelmen (l. c.)

10, Rammelsberg (ZS. G., xviii. 34); 11, Pisani (C. R., lxii. 102); 12, Hermann (l. c.); 13, Rammelsberg (Min. Ch., 459):

Schlieper found his specimen (one furnished by the author and seemingly unaltered) to consist partly of carbonate of manganese and other bases. By digestion in concentrated muriatic acid, it afforded 90·15 per cent. of silicate of manganese, and 9·85 soluble portion. The latter gave on analysis:

Mn $\ddot{C}$ 50·52 $\dot{Fe}\ddot{C}$ 8·60 $\dot{Ca}\ddot{C}$ 37·17 $\dot{Mg}\ddot{C}$ 2·44 $\dot{H}$ and loss 1·27=100.

Ten p. c. of carbonates had been previously found in the Cummington mineral, by E. Hitchcock. Allowing that the ten p. c. of carbonates in Schlieper's specimen had been formed at the expense of the bases in the rhodonite, and also that there was some free silica in minute points or grains, as was obvious to the eye, the oxygen ratio cannot be taken as different from that of rhodonite.

Hermann's *Mangan-amphibol* (l. c.) was based on an analysis of this Cummington mineral.

Ruprecht, who published his first analysis of the species in 1782, obtained $\ddot{Si}$ 55·06, manganese 35·15, iron 7·04, $\ddot{\bar{Al}}$ 1·56, water 0·78=99·59. Huot based his species *Kapnikite* on this old analysis.

Brandes obtained for the *Hydropite*, a rose-colored ore from Kapnik, having G.=2·8 (Schw. J., xxvi.) $\ddot{Si}$ 53·50, $\dot{Mn}$ 41·93, $\dot{Fe}$ 1·00, $\ddot{\bar{Al}}$ 1·24, $\dot{H}$ 3·00; it has been considered a tersilicate, with the formula $\dot{Mn}^2\ddot{Si}^3$; but it was probably an impure rhodonite.

Pyr., etc.—B.B. blackens and fuses with slight intumescence at 2·5; with the fluxes gives reactions for manganese; fowlerite gives with soda on charcoal a reaction for zinc. Slightly acted upon by acids. The calciferous varieties often effervesce from mechanical admixture with carbonate of lime. In powder, partly dissolves in muriatic acid, and the insoluble part becomes of a white color. Darkens on exposure to the air, and sometimes becomes nearly black.

Obs.—Occurs at Longban, near Philipstadt in Sweden, in iron ore beds, in broad folia, and also granular massive, the Paisberg iron mine, where it occurs, being the origin of the name *paisbergite;* also at Elbingerode, in the Harz; in the district of Katherinenburg in the Ural; with tetrahedrite at Kapnik in Transylvania; in Cornwall, etc.

Occurs in Cummington, Mass., and some of the neighboring towns, in boulders; also in Warwick, Mass.; in an extensive bed on Osgood's farm, Blue Hill Bay, Maine; in Irasburg and Coventry, Vt.; near Winchester and Hinsdale, N. H.; at Cumberland, R. I.; *fowlerite* at Hamburg and Stirling, New Jersey.

Named from *ῥόδον, a rose,* in allusion to the color. The name is attributed to Jasche by Germar (1819), but is not in the Kleine Min., Schriften of Jasche (1817).

Alt.—There are two prominent methods of alteration, which may act separately or together. (1) Through the strong tendency of the protoxyd of manganese to pass to a higher state of oxydation; in which process the red color changes to brown or black, commencing with the exterior, which becomes a black crust to the mass. Indefinite mixtures thus result, which may be either partly silicate, or wholly one or more oxyds of manganese. (2) Through the tendency of the protoxyd of manganese and other protoxyds present to unite with carbonic acid afforded by alkaline carbonated waters, this causing the silicate to be penetrated with carbonate of manganese, and often also with carbonate of lime or iron. The color of the result after this latter method is usually grayish-red to grayish-white, and sometimes brown.

I. *By Oxydation; not Hydrated or Carbonated.*

A. **MARCELINE** *Berthier* (Ann. Ch. Pharm., li. 79, 1832). Color grayish-black to iron-black; lustre submetallic; G.=3·8; H.=5·5–6. From St. Marcel in Piedmont. *Heteroclin* Breith. (*Evreinoff,* Pogg., xlix. 204, 1840) is from the same locality, and of the same nature, as recognised by Breithaupt.

B. DYSNITE *v. Kobell* (Grundz., 328, 1838) is Thomson's *sesquisilicate of M.*, from Franklin, N. J (Ann. Lyc. N. York, l. c.), an iron-black ore, with G.=3·67; it is altered fowlerite. Von Kobel cites Thomson's analysis (see below), and gives no description of his own.

II. *By Oxydation; Hydrated.*

STEATOPHITE, Wittingite, Neotokite, are names of results of this kind of alteration. They are found along with rhodonite. They contain about 35 p. c. of silica. See NEOTOCITE under HYDROUS SILICATES. Opsimose of Beudant and Klipsteinite of v. Kobell are names of a similar hydrous silicate containing about 25 p. c. of silica.

III. *Carbonated.*

A. ALLAGITE *Jasche* (Germar, Schw. J., xxvi. 112, 1819; Grunmanganerz *Jasche.*, Kleine Min. Schriften, 10, 1817), from Schebenholze, near Elbingerode in the Harz, is either dull-green or reddish-brown, and affording du Menil (Gilb. Ann., lxi. 197) 7·5 p. c. carbonic acid. The name *Allagite*, like *Rhodonite*, is not in the Kleine Schriften of Jasche, but is attributed to Jasche by Germar.

B. PHOTICITE (*Germar*, Schw. J., xxvi. 116; Photizit *Brandes*, ib., 138) is yellowish-white, isabella- and wax-yellow, greenish-gray, pearl-gray, to rose-red; G.=2·8—3, from the same locality with the allagite. It afforded Brandes (ib., 136) 11 to 14 p. c. of carbonic acid, with some water. Corneous manganese (*Horn-mangan* of Jasche) is of similar nature, it containing 5 to 10 p. c. of carbonic acid; color brown to gray. And so also the Cummington rhodonite, which afforded Schlieper 10 p. c. or more of carbonates.

Analyses: 1, Berthier (l. c.); 2, Berzelius (Schw. J., xxi. 254); 3, Evreinoff (Pogg., xlix. 204); 4, Damour (Ann. d. M., IV., J. pr. Ch., xxviii. 284); 5, Thomson (Lyc. Nat. Hist., N. Y., iii. 33): 6, 7, du Menil (l. c.); 8–10, Brandes (l. c.):

9. " *gyh.*	36·00	6·00	0·50	37·39	——	——	6·00	14·00	=99·89 Brandes
10. *Horn-manganese*	35·00	——	0·25	57·16	——	——	2·50	5·00	=99·91 Brandes.

Bustamite altered to kaolin has been described by Ebelmen (Ann d. M., IV. vii. 1) and Damour (Bull. G. Soc., vii. 224).

Berthier obtained for a Graubündten (Grisons) ore (Ann. Ch. Phys., li. 79) $\ddot{\mathrm{Si}}$ 15·3, $\bar{\mathrm{M}}\mathrm{n}$ 80·9, $\bar{\mathrm{F}}\mathrm{e}$ 1·0, $\bar{\mathrm{A}}\mathrm{l}$ 1·0=98·2; and Schweizer for the same (J. pr. Ch., xxiii. 278) $\ddot{\mathrm{Si}}$ 15·50, $\bar{\mathrm{M}}\mathrm{n}$ 77·34, $\bar{\mathrm{F}}\mathrm{e}$ 3·70, $\dot{\mathrm{C}}\mathrm{a}$ 1·70, $\dot{\mathrm{H}}$ 1·76=100.

The ores, as alteration continues, graduate into true oxyds of manganese. A kind from Pesillo (called *Pesillite* by Huot, Min., 1841) afforded Berthier $\ddot{\mathrm{Si}}$ 6·8, $\bar{\mathrm{M}}\mathrm{n}$ 84·2, O, $\dot{\mathrm{H}}$ 6·7, $\bar{\mathrm{F}}\mathrm{e}$ 2·8, $\dot{\mathrm{C}}\mathrm{o}$ 0·8; it had lost nearly all of the silica in the change.

242. BABINGTONITE. *Levy*, Ann. Phil., II. vii. 275, 1824.

Triclinic, but, like rhodonite, approaching pyroxene in form. Observed planes as in the annexed figures. $I \wedge I = 87° 24'$, Dauber; 87° 26′, Levy

$O \wedge I = 92° 32'$
$O \wedge I' = 112\ 12$
$O \wedge 1' = 132\ 24$

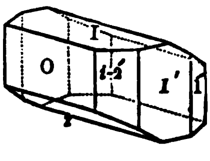
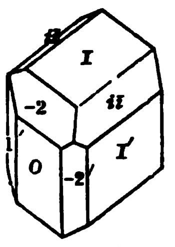
218



219



H. = 5·5—6. G. = 3·35 — 3·37; 3·355, Thomson; 3·366, Rammelsberg. Lustre vitreous, splendent. Color dark greenish-black; thin splinters green in the direction of *O*, and brown transversely. Faintly translucent; large crystals opaque, or faintly subtranslucent. Fracture imperfectly conchoidal.

Comp.—3 $\dot{R}^3\dddot{Si}^3+\dddot{\overline{Fe}}\dddot{Si}^3$, Rammelsberg; $=(\frac{3}{4}\dot{R}^3+\frac{1}{4}\dddot{\overline{Fe}})\dddot{Si}^3=$, if 9 $\dot{R}=2\dot{Fe}+1{\cdot}5\dot{Mn}+5{\cdot}5\dot{Ca}$, Silica 50·1, sesquioxyd of iron 11·1, protoxyd of iron 10·0, protoxyd of manganese 7·4, lime 21·4=100. Analyses: 1, Arppe (Berz. Jahresb., xxii. 205); 2, R. D. Thomson (Phil. Mag., xxvii. 123); 3, Rammelsberg (Pogg., ciii. 287, 304):

	$\dddot{Si}$	$\dddot{\overline{Fe}}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Fe}$	$\dot{Mn}$	$\dddot{\overline{Al}}$
1.	54·4	——	2·2	19·6	21·3	1·8	0·3, ign. 0·9=100·5 Arppe.
2.	47·46	——	2·21	14·74	16·81	10·16	6·48, ign. 1·24=99·10 Thomson.
3.	51·22	11·00	0·77	19·32	10·26	17·91	——, ign. 0·44=100·92 Ramm.

Pyr., etc.—B.B. fuses at 2·7 to a black magnetic globule, and with the fluxes gives reactions for iron and manganese. Unacted upon by acids.

Obs.—Babingtonite occurs in distinct crystals at Arendal, in Norway, associated with epidote and massive garnet, and in the Shetland Isles, imbedded in white quartz. It was named after Dr. Babington; it resembles some dark varieties of pyroxene.

In the United States it is said to coat crystals of feldspar, at Gouverneur, St. Lawrence Co., N. Y. On cryst., see Dauber, Pogg., xciv. 402.

Small black polished crystals coating mica slate, or micaceous gneiss, at Athol, Mass., referred by Shepard to Babingtonite, may possibly belong here.

243. SPODUMENE. *D'Andrada*, Scherer's J., iv. 30, and J. de Phys., li. 240, 1800. Triphane *H.*, Tr., iv. 1801.

Monoclinic. $C=69°\ 40'$ $I\wedge I=87°$, $O\wedge 2\text{-}\grave{\imath}=130°\ 30'$.

[a] With some potash; in 5, 6, 7, magnesia, *tr.*

In a specimen from Sterling, Mass., Hagen found S̈i 65·247, A̶l, F̶e 27·556, and in another from Tyrol, S̈i 66·027, A̶l 26·451. G. J. Brush's earlier analyses (Am J. Sci., II. x. 370) are rejected by him.

Pyr., etc.—B.B. becomes white and opaque, swells up, imparts a purple-red color (lithia) to the flame, and fuses at 3·5 to a clear or white glass. The powdered mineral, fused with a mixture of bisulphate of potash and fluor on platinum wire, gives a more intense lithia reaction. Not acted upon by acids.

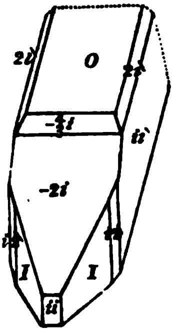
Obs.—Occurs on the island of Utö in Südermanland, Sweden, with magnetic iron ore, quartz, tourmaline, and feldspar; also near Sterzing and Lisens in the Tyrol, and of a pale-green or yellowish color, imbedded in granite, at Killiney Bay, near Dublin, and at Peterhead in Scotland.

Occurs in granite at Goshen, Mass., associated at one locality with blue tourmaline and beryl, also at Chesterfield, Chester, Norwich, and Sterling, Mass.; at Windham, Maine, near the bridge, along with garnet and staurotide; at Winchester, N. H.; at Brookfield, Ct., a few rods north of Tomlinson's tavern, in small grayish or greenish-white individuals looking like feldspar; near Ballground, Cherokee Co., Ga. At Norwich, Mass., it is associated with triphyline, mica, beryl, and albite; one crystal from this locality was 16½ inches long, and 10 inches in girt. Fig. 221 is of a crystal from this locality, and is two-thirds the natural size. Well terminated crystals, having the terminal planes 2-ì, 1, *O*, have been observed by A. B. Kittredge' at the Sterling locality. Crystals also occur at Goshen.

Named from σποδός, *ashes*, because the mineral becomes ash-colored before the blowpipe.

The following are the angles obtained by the author, with the common goniometer, from the Norwich crystals: *O* ∧ *i-i*=69° 40′, *i-i* ∧ *I*=138° 30′, *i-i* ∧ *i-3̀*=107°, 2-ì ∧ 2-ì, top,=80°, *i-i* ∧ 2-ì =139° 45′, *i-i* ∧ 2-ì=103°, *i-i* ∧ 2=116°, *i-i* ∧ 1=100° 30′, *i-i* ∧ *x*=140°, *i-i* ∧ 2=134°, *i-3̀* ∧ 2= 142°, *I* ∧ 2=144°, 1 ∧ 1=117°, 2 ∧ 2=92°.

244. PETALITE. Petalit *d'Andrada*, Scherer's J., iv. 36, 1800. Castor (fr. Elba) *Breith.*, Ann. Ch. Pharm., lxix. 436, 1849.



222

Monoclinic. *C*=67° 34′=*O*, below, on *i-i*; *I* ∧ *I*=86° 20′ (87°—87½° observed), *O* ∧ 2-ì=126° 2′; *a* : *b* : *c*= 0·64511 : 1 : 0·8670.

Observed planes: *O*; vertical, *I*, *i-ì*, *i-2̀*, *i-i*; clinodome, 2-ì; hemidomes, -¼-*i*, -2-*i*, -1-*i*, 4-*i*, ⅜-*i*? (cleavage).

O ∧ *I*=105° 8′	*O* ∧ 4-*i*, adj.,=90° 23′
O ∧ *I*, back,=74 52	*O* ∧ ⅜-*i*, adj.,=117 27
O ∧ -¼-*i*=149 7	-2-*i* ∧ ⅜-*i*, ov. *i-i*,=101 10
O ∧ -2-*i*=141 23	*i-i* ∧ -2-*i*=151 3
O ∧ -1-*i*=154 26	*i-ì* ∧ *I*=136 50

8. "	77·90	15·85	3·52	0·53,	$\bar{\ddot{Fe}}$ 0·51, $\dot{K}$, $\dot{Ca}$, *tr.*, $\dot{Mg}$ 0·26 ign 0·70 S. & B.
9. Elba, *Castorite*	78·01	18·86	2·76 (with *tr.* $\dot{K}$, $\dot{Na}$)		=100·24 Plattner. G.=2·392.

The protoxyds in castorite are less than in petalite in the analysis made. But its cleavages, according to Rose, are like those of petalite, and its optical characters, according to Descloizeaux. Breithaupt still urges that they are distinct (B. H. Ztg., xxv. 35), and mentions their difference in sp. gr. as a prominent distinction.

Pyr., etc.—Gently heated emits a blue phosphorescent light. B.B. on charcoal becomes glassy, subtransparent, and white, and melts only on the edges; gives the reaction of lithia. With borax it forms a clear, colorless glass. Not acted on by acids.

Obs.—Petalite occurs at the iron mine of Utö, accompanying lepidolite, tourmaline, spodumene, and quartz; on Elba (*castorite*) in attached crystals; at Bolton, Mass., with scapolite; according to Bigsby, in a boulder containing tremolite, at York, near Toronto, Canada.

Lithia was first discovered in this mineral by Arfvedson. The name *petalite* is from πεταλον, *a leaf*, and alludes to the cleavage.

On cryst. of castorite and petalite, see Descl., Ann Ch. Phys., IV. iii. 264, 1864, and Pogg., cxxii. 648.

Descloizeaux, who gives the above figure, points out the isomorphism with spodumene, and the fact that the O. ratio differs by a multiple of 2 for the silica, it being 1 : 4 : 10 for spodumene and 1 : 4 : 20 for petalite.

245. KUPFFERITE.

Kupfferit (fr. the Tunkinsk Mts.) *R. Hermann*, Bull. Soc. Nat. Moscou, xxxv. 243, 1862. Anthophyllite pt. Antholith pt. *Kenng.*

Monoclinic. $I \wedge I$=124° 15′–124° 30′. Cleavage: I perfect. In aggregations of prisms, like actinolite.

H.=5·5. G.=3·08, fr. Ilmen Mts. Lustre vitreous. Color emerald-green; brownish on weathering. Translucent in thin splinters.

Comp.—$\dot{Mg}\ddot{Si}$, with but little $\dot{Fe}$ replacing the Mg, like enstatite, it being an *enstatite hornblende* colored by chrome. Analyses: 1, Hermann (l. c., and J. pr. Ch., lxxxviii. 195); 2, 3, Heintz (Pogg., lviii. 168); 4, Lappe (Pogg., xxxv. 486); 5, Sackur (Ramm. Min. Ch., 472); 6, Thomson (Rec. Gen. Sci., iii. 336):

	$\ddot{Si}$	$\bar{\ddot{Al}}$	$\bar{\ddot{Cr}}$	$\dot{Fe}$	$\dot{Ni}$	$\dot{Mg}$	$\dot{Ca}$	Alk.	Ign.
1. Ilmen Mts.	57·46	——	1·21	6·05	0·65	30·88	2·94	*tr.*	0·81=100 Hermann.
2. Pinel, *asbest.*	59·23	0·19	——	8·27	——	31·02	——	—	1·31=100 Heintz.
3. Tschussovaja	58·72	0·19	——	8·10	——	30·90	——	—	1·58=99·49 Heintz.
4. Koruk	58·48	——	——	9·22	——	31·38	0·04	—	——, $\dot{Mn}$ 0·88=100 L.
5. Kupferberg *anth.*	55·59	4·03	——	8·40	——	30·46	1·76	—	——=100·24 Sackur.
6. Perth, Can., "	57·60	3·20	——	2·10	——	29·30	3·55	—	3·55=99·30 Thomson.

Analyses 2–6 are referred here because of the approximation to kupfferite in composition. The Perth mineral (received thus labelled by Dr. Thomson from Dr. Holmes) is almost purely a

magnesian silicate; it was a "congeries of imperfect crystals, and looked like anthophyllite;' G.=2·707.

Pyr., etc.—In the closed tube traces of water; otherwise unchanged. B.B. in the forceps becomes opaque white, but does not fuse. In borax dissolves, giving a chrome-green glass.

Obs.—The original kupfferite, from a graphite mine in the Tunkinsk Mts., is a chromiferous amphibole. The analyses here given are from a mineral of similar kind from near Miask, in the Ilmen Mts. The former has not been analyzed. Kokscharof has also found it near the Sanarka river, Urals.

Named after the Russian physicist Kupffer.

246. ANTHOPHYLLITE. Anthophyllit (fr. Norway) *Schumacher*, Verzeichn., 96, 1801. Antophyllit *Karst.*, Tab., 32, 1808. Anthogrammit *Breith.*, Char., 29, 1820. Antholith *Breith.*, Uib., 38, 1830.

Orthorhombic. $I \wedge I = 125°$ to $125°\ 25'$. Observed planes: I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$. Cleavage: $i\text{-}\bar{i}$ perfect, I less so, $i\text{-}\breve{i}$ difficult. Commonly lamellar, or fibrous massive; fibres often very slender.

H.=5·5. G.=3·1—3·2. Lustre somewhat pearly upon a cleavage-surface. Color brownish-gray, yellowish-brown, brownish-green, sometimes submetallic. Streak uncolored or grayish. Translucent to subtranslucent. Brittle. Double refraction positive; optical axes in the brachydiagonal section.

Comp.—$\dot{\mathrm{F}}\mathrm{e}\ \ddot{\mathrm{S}}\mathrm{i} + 3\ \dot{\mathrm{M}}\mathrm{g}\ \ddot{\mathrm{S}}\mathrm{i} = (\frac{1}{4}\ \dot{\mathrm{F}}\mathrm{e} + \frac{3}{4}\ \dot{\mathrm{M}}\mathrm{g})\ \ddot{\mathrm{S}}\mathrm{i}$=Silica 55·5, magnesia 27·8, protoxyd of iron 16·7 =100. Analyses: 1, L. Gmelin (Leonh. Orykt., 515, 1826); 2, Vopelius (Pogg., xxiii. 355); 3, Pisani (Descl. Min., i., 536):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\mathrm{A}}\mathrm{l}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
1. Kongsberg	56	3	18	4	23	2	——=101 Gmelin.
2. "	56·74	——	18·94	2·38	24·35	——	1·67=99·08 Vopelius.
3. "	56·16	2·65	14·13	0·91	23·19	1·51	2·38=100·93 Pisani.

GEDRITE of Dufrenoy (Ann. d. M., III. x. 582, 1836) has a different composition from that of anthophyllite; but it is still referred here by Descloizeaux on the ground of *optical identity* and similarity of cleavage.

Analyses: 1, Dufrenoy (l. c.); 2, 3, Pisani (L'Institut, 1861, 190):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\mathrm{A}}\mathrm{l}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
1.	38·81	9·31	45·83	4·13	0·67	2·30=101·05 Dufrenoy.
2.	42·86	16·52	18·82	15·51	1·90	4·50=100·11 Pisani.
3.	43·58	17·07	15·96	18·30	0·75	3·92=99·58 Pisani.

Pisani's analyses afford the O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$, 11 : 8 : 23½ : 3½.

Pyr., etc.—B.B. fuses with great difficulty to a black magnetic enamel; with the fluxes gives reactions for iron; unacted upon by acids.

Obs.—Occurs in mica schist with hornblende and mica in thin and long plates and fibres near Kongsberg in Norway, and with gray cobalt near Modum.

This species, originally instituted upon the Norwegian mineral analyzed by Gmelin and Vopelius, and regarded as distinct by many later authors, including Mohs, but united to hornblende by others, has recently been proved to be an independent species by Descloizeaux (Min., i. 75), whose optical examinations have shown that the crystals are *orthorhombic* instead of monoclinic. Only the mineral of the Norwegian localities above mentioned is at present here included, the so-called anthophyllite from Fiskenaes in Greenland (occurring with sapphirine), from Bavaria, Finland, and other Norwegian localities, besides the *cummingtonite*, of Cummington, Mass., being true *hornblende* in optical characters. Descloizeaux has later announced (C. R., lxii., 987) that some anthophyllite is monoclinic. The *gedrite* is from the valley of Héas, near Gèdres, France, and contains microscopic black spinels (*picotite*).

Named from *anthophyllum*, *the clove*, in allusion to the clove-brown color, as Schumacher states.

246A. PIDDINGTONITE, Haidinger (Ber. Ak. Wien, xli., 251, 1860). The ash-gray mass of the meteorite of Shalka, in Bancoorah, consisting in part of grains having two easy cleavages inclined to one another 100°, with H.=6·5; G.=3·412, Haid., 3·66, Piddington; and fracture resinous, and containing small imbedded grains of chromite. Von Hauer obtained $\ddot{\mathrm{Si}}$ 57·66, $\ddot{\overline{\mathrm{Al}}}$ *tr.*, $\dot{\mathrm{Fe}}$ 20·65, $\dot{\mathrm{Mg}}$ 19·00, $\dot{\mathrm{Ca}}$ 1·53=98·84, which is nearly the composition of anthophyllite. The meteorite was first described by H. Piddington in the J. Asiat. Soc. Bengal, xx. 299, 1852.

247. AMPHIBOLE. Skörl (=Schörl) pt. *Wall.*, 1747 (excluding Amiantus, Bergkork, etc. and Asbestus). Skörl pt., Strålskörl (=Strahlstein) *Cronst.*, Min., 1758 (excl. Asbestus=Amianthus; and Bergkork, id. Hornblende *Wern.*, Bergm. J., 1789 (excl. Strahlstein and Asbest). Hornblende *Karst.*, Tab., 1791 (excl. Strahlstein, Tremolit, and Asbest). Id. (excl. also Smaragdit pt.) *Karst.* Tab., 1800, 1808; id. *Ullmann*, 1814, and *Jameson*, 1817. Amphibole (incl. Actinote) *H.*, Tr., 1801 (excl. Grammatite=Tremolite and Asbeste). Amphibole (incl. Actinote and Grammatite) *H.*, Tabl., 1809 (excl. Asbeste). Heterotyp (incl. Asbestus, Bronzite, Hypersth., Anthoph. with other varieties) *Hausm.*, Handb., 1818. Hornblende *Jameson*, Syst., 1820 (excl. Actinolite, Tremolite, Asbestus, Carinthine).

Monoclinic. *C*=75° 2′, *I* ∧ *I*=124° 30′, *O* ∧ 1-ì=164° 10′, *a* : *b* : *c*= 0·5527 : 1 : 1·8825. Observed planes: *O*; vertical, *I*, i-i, i-3, i-ì, i-3̀; clinodome, 2-ì, 4-ì; hemidome, 1-ī, 2-ī, –1-ī; hemioctahedral planes in zone *O* : *I*, 1, 2, –1; id. in zone 1 : i-ì, 3-3̀, 5-5̀, –3-3̀.

3-3̀ ∧ 3-3̀=99 30

Crystals sometimes stout, often long and bladed. Cleavage: *I* highly perfect; i-i, i-ì, sometimes distinct. Lateral planes often longitudinally striated. Twins: composition-face i-i, as in f. 226 (simple form f. 225), and 230. Imperfect crystallizations: fibrous or columnar, coarse or fine, fibres often like flax; sometimes lamellar; also granular massive, coarse or fine, and usually strongly coherent, but sometimes friable.

H.=5–6. G.=2·9–3·4. Lustre vitreous to pearly on cleavage-faces; fibrous varieties often silky. Color between black and white, through various shades of green, inclining to blackish-green. Streak uncolored, or paler than color. Sometimes nearly transparent; usually subtranslucent—opaque. Fracture subconchoidal, uneven. Bisectrix, in most varieties, inclined about 60° to a normal to O, and 15° to a normal to $i\text{-}i$; and double refraction negative. See exceptions, p. 235.

Comp., Var.—$\dot{R}\ddot{S}i$, and $(\dot{R}^3\,\overline{R})(\ddot{S}i, \ddot{\overline{Al}}^{\frac{2}{3}})$ as for pyroxene. Alumina is present in most amphibole, and when so it usually replaces silica. $\dot{R}$ may correspond to two or more of the bases $\dot{M}g$, $\dot{C}a$, $\dot{F}e$, $\dot{M}n$, $\dot{N}a$, $\dot{K}$, $\dot{H}$; and $\overline{R}$ to $\ddot{\overline{Al}}$, $\ddot{\overline{F}}e$, or $\ddot{\overline{M}}n$. $\ddot{\overline{F}}e$ sometimes replaces silica, like $\ddot{\overline{Al}}$. Rammelsberg made out the general conformity of amphibole to the pyroxene formula by discovering that the iron in both species was often partly sesquioxyd (Pogg., ciii. 284, and Min. Ch., 468). Yet the analyses do not all accord with this view, part giving the ratio 1 : 2¼, unless the water is made basic. Much amphibole, especially the aluminous, contains some fluorine. The base *lime* is absent from some varieties, or nearly so.

The name *Amphibole*, proposed by Haüy, has the precedence, because Haüy first rightly appreciated the species, as he had done for pyroxene, and gave it, and not any of its varieties, the name. In his Traité, in 1801, he brought together *hornblende* and *actinolite*; and by 1809 he had added to the group the third prominent variety, *tremolite*; while in all other works not taking their views from him, these three minerals still stood as distinct species. *Asbestus* was annexed to the series by Hausmann in 1813, though kept separate long afterward by many other authors.

The *varieties* of amphibole are as numerous as those of pyroxene, and for the same reasons; and they lead in general to similar subdivisions.

I. CONTAINING LITTLE OR NO ALUMINA.

1. *Magnesia-Lime Amphibole*; TREMOLITE. (Tremolit *Pini*, *de Saussure*, Voy. Alpes, iv. § 1923, 1796. Grammatite *H.*, Tr., iii. 1801. Kalamit [fr. Normark, Sw.) *Wern.*, Tasch. Min., x. 169, 1816. Calamite. Raphilite *Thom.*, Min., i. 153, 1836. Sebesit [fr. Sebes, Transylvania] in Breith. Handb., 539, 1847. Nordenskiöldit, Kenng., Ber. Ak. Wien, xii. 297, 1854.)

Colors white to dark-gray. In distinct crystals, either long bladed or short and stout; long and thin columnar, or fibrous; also compact granular massive. $I \wedge I = 124°\ 30'$. H.=5·0–6·5. G. 2·9–3·1. Sometimes transparent and colorless. Contains magnesia and lime with little or no iron; formula $(\dot{C}a\,\dot{M}g)\ddot{S}i$. Named *Tremolite* by Pini, from the locality at Tremola in Switzerland.

Grammatite (from γραμμη, *a line*) alludes to a line in the direction of the longer diagonal seen by Haüy on transverse sections of some crystals. It was substituted for tremolite by Haüy, without reason, and is a very bad substitute.

Nordenskiöldite, from Ruscula, near Lake Onega, is tremolite (Kenngott and v. Hauer, l. c.).

Raphilite, from Lanark in Canada, is tremolite in its grayish-white or but slightly greenish color, and its low specific gravity (G.=2·85, Thomson; 2·845, Hunt). But both Hunt's and Thomson's analyses give over 5·30 p. c. of protoxyd of iron. In a letter to the author (dated Sept. 21, 1864) Hunt states that he obtained in one of his trials, from material which he had purified from mixed $\dot{C}a\ddot{C}$, only 3·15 of protoxyd of iron, with $\dot{C}a$ 12·05 and $\ddot{S}i$ 57·20; and he adds that he regards this as nearer the true composition of the mineral.

1 a. NEPHRITE pt. (Pietra di hijada [fr. Mexico or Peru] *Span.* Lapis nephriticus *A. Clutius*, Dissert., 1627; *C. Bartholinus*, Opusc., 1628; *de Boot*, Gemm., 1609. Lapis Indicus *Aldrovandus*, Met., p. 706. Talcum nephriticum *Linn.*, 1768. Jade, Pierre néphrétique, *d'Argenville*, Oryct., 186, 1755; *Sage*, *de Lisle*, *etc.* Nephrit *Wern.*, Ueb. Cronst., 185, 1780. Kidney Stone. Nierenstein, Beilstein, *Germ.*)

Nephrite is in part a tough, compact, fine-grained tremolite, having a tinge of green or blue, and breaking with a splintery fracture and glistening lustre. H.=6–6·5. G.=2·96–3·1. Named from a supposed efficacy in diseases of the kidney, from νεφρός, *kidney*. It occurs usually associated with talcose or magnesian rocks.

Nephrite or jade was brought in the form of carved ornaments from Mexico or Peru soon after the discovery of America. Del Rio, in his Mexican Mineralogy (1795), mentions no Mexican locality. A similar stone comes from China and New Zealand. A nephrite-like mineral, called *bowenite*, from Smithfield, R. I., having the hardness 5·5, is serpentine in composition. The jade of de Saussure is the *saussurite* (see under ZOISITE) of the younger de Saussure, earlier named *lemanite* by Delametherie. Another aluminous jade has been called *jadeite* (q. v.) by Damour. The Easton mineral is a mixture, and has been named *pseudonephrite* (q. v.).

2. *Magnesia-Lime-Iron Amphibole*; ACTINOLITE (Strålskörl pt. *Cronst.*, l. c. Strahlstein *Germ.* Actynolite *Kirw.*, Min., i. 167, 1794. Actinolite (correct orthogr.). Schorl vert du Zillerthal

Zillerthite, *Delameth.*, T. T., ii 357, 1797. Actinote *H.*, Tr., iii 1801). Color bright-green and grayish-green. In crystals, either short or long-bladed, as in tremolite; columnar or fibrous; granular massive. G.=3—3 2. Sometimes transparent. Contains magnesia and lime, with some protoxyd of iron, but seldom more than 6 p. c.; formula $(\dot{C}a, \dot{M}g, \dot{F}e)\ddot{S}i$. The variety in long bright-green crystals is called *glassy actinolite;* the crystals break easily across the prism. The fibrous and radiated kinds are often called *asbestiform actinolite* and *radiated actinolite.* Actinolite owes its green color to the iron present.

Named actinolite from 'ακτίν, *a ray*, and λίθος, *stone*, as translation of the German *strahlstein* or *radiated stone.* Name changed to *actinote* by Haüy, without reason.

Tremolite graduates into *actinolite* through an increase in the proportion of iron, though generally easily distinguishable by its color. *Asbestus* has usually a grayish-white or greenish-white color, although actinolite in the proportion of iron; and the *raphilite* (see preceding page) appears to shade into actinolite in composition. Tremolite does not differ in color from the aluminous variety, *edenite*, from Edenville, N. Y. (p. 285).

3. *Magnesia-Iron Amphibole;* ANTHOLITE (Anthophyllite pt. (p. 231). Antholith pt. *Kenng.*, Ueb. 1859, 68, 1860). Structure as in anthophyllite. Color gray to brown; G.=3·1—3·2. Contains much magnesia, with some iron, and little or no lime. Formula $(\dot{M}g, \dot{F}e)\ddot{S}i$. Graduates into *kupfferite*, p. 230.

4. *Magnesia-Lime-Manganese Amphibole;* RICHTERITE. A variety from Paisberg is here included (anal. 34), described by Igelström, and affording the formula $(\dot{M}g, \dot{M}n, \dot{C}a, \dot{K}, \dot{N}a)\ddot{S}i$, and containing 8 to 9 p. c. of alkali, which may possibly be a result of alteration. $I \wedge I=124°$; color pale-yellowish to brown. Igelström considers the *richterite* of Breithaupt (B. H. Ztg., xxiv. 364, 1865) the same mineral, as it has the same general aspect and similar composition, excepting half less manganese; Breithaupt describes it as occurring in acicular crystals, affording the prismatic angle 133° 38′ (which is within 5′ of $I \wedge i\text{-}i$ of pyroxene); with G.=2·826; color isabella-yellow, rarely pale yellowish-brown; B.B. very fusible. It resembles the kokscharoffite from L. Baikal, though unlike it in composition (p. 242).

5. *Iron-Magnesia Amphibole;* CUMMINGTONITE (*Dewey*, Am. J. Sci., viii. 59, 1824. Anthophyllite pt. Not Cummingtonite [=Rhodonite] *Ramm.*). Color gray to brown. Usually fibrous or fibro-lamellar, often radiated. G.=3·1—3·32. Contains much iron, with some magnesia, and little or no lime. Formula $(\dot{F}e, \dot{M}g)\ddot{S}i$. Named from the locality, Cummington, Mass.

6. *Iron-Manganese Amphibole;* DANNEMORITE (Jern-och-manganoxidulrik Hornblende *A. Erdmann*, Dannemora Jernm., 52, 1851. Dannemorit *Kenng.*, Ueb. 1855, 61, 1856). Color yellowish-brown to greenish-gray. Columnar or fibrous, like tremolite and asbestus. Contains iron and manganese; formula $(\dot{F}e, \dot{M}n)\ddot{S}i$. In thin pieces B.B. fuses to a dark slag. *Asbeferrite* of Igelström (B. H. Ztg., xxvi. 23, 1867) is similar; it is grayish-white to ash-gray, and like a gray asbestus; in acids not soluble (anal. 39). The proportion of $\dot{M}n$ is not stated, and it may be cummingtonite.

7. *Iron Amphibole;* GRÜNERITE (Pyroxene ferrugineux (fr. Collobrières) *Grüner*, C. R., xxiv. 794; Grünerit *Kenng.*, Min., 69, 1853). Asbestiform, or lamellar-fibrous. Lustre silky: color brown; G.=3·713. Formula $\dot{F}e\ddot{S}i$. Optical properties those of amphibole, according to Descloizeaux (Min., i. 59).

Appendix. 8. ASBESTUS (Ἀμίαντος λίθος *Dioscor.*, v. 155. [Not ἄσβεστος [=Quicklime] *Dioscor.*, v. 133.] Asbestos, Linum vivum, Amiantus, *Plin.*, xix. 4, xxxvi. 31. Lapis Carystius (fr. Carystum) *Pausanias.* Lana montana. Amiantus, Asbestus, *Agric.*, Foss., 253, 1546; *Wall.*, Min., 140, 143, 1747 (Caro montana or Bärgkött=Mountain leather, and Suber montanum or Bärgkoark=Mountain cork, being included.) Asbestus, Amianthus, Carystine (=Mtn. leather and cork), *Hill*, Foss., 166, 1771. Kymatin *Breith.*, Uib. 1830, Char., 113, 1832. Byssolite (fr. Bourg d'Oisans) *Saussure*, Voy. Alpes, § 1696; Asbestöide (ib.) *Vauq. & Macquart*, Bull. Soc. Philom., No. 54, 1797; Amianthoide (ib.) *Delameth.*, T. T., ii. 364, 1797). Tremolite, actinolite, and other varieties of amphibole, excepting those containing much alumina, pass into fibrous varieties, the fibres of which are sometimes very long, fine, flexible, and easily separable by the fingers, and look like flax. These kinds, like the corresponding of pyroxene, are called *asbestus* (fr. the Greek for *incombustible.*) Pliny supposed it a vegetable product, although good for making *incombustible* cloth, as he states. The amianthus of the Greeks and Latins was the same thing; the word meaning *undefiled*, and alluding to the ease of cleaning the cloth by throwing it into the fire. The colors vary from white to green and wood-brown. The name *amianthus* is now applied usually to the finer and more silky kinds. Much that is so called is *chrysotile*, or fibrous serpentine, it containing 12 to 14 p. c. of water. *Mountain leather* is a kind in thin flexible sheets, made of interlaced fibres; and *mountain cork* (bergkork) the same in thicker pieces; both are so light as to float on water, and they are often hydrous. *Mountain wood* (Bergholz, Holzasbest, *Germ.*) is compact fibrous, and gray to brown in color, looking a little like dry wood.

Byssolite (Amianthoid, asbestoid) fr. Bourg d'Oisans in Dauphiny, is of an olive-green color.

coarse and stiff fibrous, and has G.=3·0; it is a fibrous variety of the *iron-manganese amphibole*, according to Vauquelin & Macquart (l. c.). It occurs associated with a black oxyd of manganese.

II. ALUMINOUS.

9. *Aluminous Magnesia-Lime Amphibole.* (*a*) EDENITE. (Edenit *Breith.*, Handb., 558, 1847). Color white to gray and pale-green, and also colorless; G.=3·0—3·059, Ramm.; 2·9, Breith. Resembles anthophyllite and tremolite. Formula $(\dot{\mathrm{M}}\mathrm{g}, \dot{\mathrm{C}}\mathrm{a})(\ddot{\mathrm{S}}\mathrm{i}, \dddot{\overline{\mathrm{A}}}\mathrm{l}^{\frac{2}{3}})$. Named from the locality at Edenville, N. Y. To this variety belong various pale-colored amphiboles, having less than five p. c. of oxyds of iron. Breithaupt makes the edenite *triclinic* in B. H. Ztg., xxiv. 428, and he says that this is confirmed by Dauber. On an examination of crystals, the author sees no reason for adopting this conclusion.

(*b*) SMARAGDITE *Saussure* (Voy. Alpes, iv. § 1313, 1362, 1796. Diallage verte pt. *H.*, 1801; Green Diallage pt. Diallagon *Ullmann*, Tab., 90, 1814). A thin-foliated variety, of a light grass-green color, resembling much common green diallage. According to Boulanger it is an aluminous magnesia-lime amphibole, containing less than 3½ p. c. of protoxyd of iron, and is hence related to edenite and the light green Pargas mineral. Descloizeaux observes (Min., i. 90) that it has the cleavage, and apparently the optical characters, of amphibole. H.=5; G.=3, Vauq.; 3·10, Boulanger. It forms, along with whitish or greenish saussurrite, a rock. The original mineral is from Corsica, and the rock is the *corsilyte* of Pinkerton, and the *verde di Corsica duro* of the arts.

A similar smaragdite from Bacher consists, according to Haidinger, of alternate laminæ of amphibole and pyroxene in twin composition.

The *euphotide* of the Alps resembles corsilyte in containing a smaragdite-like mineral (*green diallage*). But Hunt states that the mineral has the cleavage of pyroxene, which our own examinations have not succeeded in confirming.

10. *Aluminous Magnesia-Lime-Iron Amphibole.* (*a*) PARGASITE; (*b*) HORNBLENDE. (Corneus fissilis pt., Corneus solidus pt., C. crystallisatus pt, Hornbärg, Skiörl pt., *Wall.*, Min., 138, 139, 1747. Skörl pt., Basaltes pt., Bolus particulis squamosis pt., *Cronst.*, 70, 82, 1758. Schorl opaque rhomboidal pt, Schorl argileux pt., *de Lisle*, Crist., ii. 389 (pl. iv, f. 97, 99), 424, 1783. Basaltische Hornblende *Wern.*, Bergm. J., 1789 (incl. also augite). Basaltische H. (augite excl.) *Wern.*, 1792, and later; *Karst.*, Tab, 1800. Pargasit *Steinheil*, 1814, Tasch., Min. 1815, 301. Amphibolit *Breith.*, Char., 1823, Uib., 34, 1830. Diastatit (fr. Wermland) *Breith.*, Char, 184, 1832. Syntagmatit (fr. Vesuvius), Wallerian, *Breith.*, B. H. Ztg., xxiv. 428, 1865.

Colors bright, dark, green, and bluish-green to grayish-black and black. $I \wedge I = 124° \ 1' - 124° \ 25'$; G.=3·05—3·47. *Pargasite* is usually made to include green and bluish-green kinds, occurring in stout lustrous crystals, or granular; and *hornblende* the greenish-black and black kinds, whether in stout crystals or long bladed, columnar, fibrous, or massive granular. But no line can be drawn between them. Pargasite occurs at Pargas, Finland, in bluish-green and grayish-black crystals.

Optical characters in general the same as for tremolite and actinolite (p. 233). But in one black crystal of hornblende (fr. Bilin ?) Descloizeaux found one bisectrix to be parallel to the plane *i-i*, and the other normal to it. Again, in the bluish or black pargasite, from Pargas, the bisectrix is inclined 32° 58′ to a normal to *O*, and 108° to a normal to *i-i*; and double refraction is *positive*. Descloizeaux observes that these distinctions are not sufficient to warrant the separation of these minerals.

(*a*) *Diastatite* is a black hornblende from Nordmark in Wermland, stated by Breithaupt to have $I \wedge I = 120° \ 20'$, and G.=3·08—3·11. (*b*) *Syntagmatite* is the Vesuvius black hornblende, analyzed by Rammelsberg (No. 29), in which he found $I \wedge I = 124° \ 8'$, G.=3·272.

(*c*) According to Breithaupt, $I \wedge I$ in two hornblendes from Greenland is 123° 59′ and 124° 0′, with G.=3·462 and 3·383; two from Arendal in Norway, 124° and 124° 1½′, with G.=3·301 and 3·229; one from Persberg in Sweden, 124°, with G.=3·318; two from Schmalzgrube, near Marienberg in Saxony, 124° 5′ and 124° 11′, with G.=3·333 and 3·290; one from Rhonsberg in Bohemia, 124° 6′, with G.=3·352. The preceding are of Breithaupt's *Amphibolus ferrosus*.

For a basaltic hornblende, from Wetterau or Bilin (*A. basalticus* Br.) analyzed by Bonsdorff and Struve (Anal. 17, 21), Breithaupt gives $I \wedge I = 124° \ 39' \ 38''$, and G.=3·17—3·25; for one from the zircon-syenite of Laurvig and Fredriksvärn in Norway (*A. saxosus* Br.) $I \wedge I = 124° \ 7'$, and G=2·26—2·29; for one of greenish-black color from Ersby near Pargas in Finland, analyzed by Hisinger and Bonsdorff, anal. 10, 11 (*A. medius* Br.), $I \wedge I = 124° \ 15'$, and G.=3·14—3·17; for one of green to greenish-black color, from Saualpe in Carinthia, analyzed by Clausbruch, anal. 20 (*A. Carinthinus* Br., and *Carinthine* W.), $I \wedge I = 124° \ 22'$, and G.=3·08—3·10; for one from Pargas, occurring in limestone with chondrodite, etc., analyzed by Bonsdorff and Gmelin (*A. pargasites* Br., or *Pargasite*), $I \wedge I = 124° \ 10'$, and G.=3·06—3·08; for one of greenish-black to blackish-green color, from Kongsberg in Norway, analyzed by Kudernatsch (*A. macrodiagonalis* Br.) $I \wedge I = 124° \ 26'$ and G.=3·06—3·08

Diastatite of Breithaupt (*A. diastaticus*), in its angle $I\wedge I=120^\circ\ 20'$, if this be not an accidental irregularity, diverges widely from true hornblende. Breithaupt has called a velvet-black hornblende from Nordmark in Wermland *Hemiprismatischer Amphibol* (Char., 135, 1832; Handb., iii 546); it is stated to have $I\wedge I=124^\circ\ 26'$, and to be *triclinic*, the angle between the macrodiagonal and the left face of a clinodome being 27° 40′, and that for the right face 27° 54′, and the cleavages parallel to the prismatic planes I, I', unequal. G.=3·16–3·18. The analyses by Bonsdorff and Hisinger, Nos. 11, 28, he refers here. He has recently named it *Hemiprismatites Wallerianus* or *Wallerian*. Breithaupt also observes that his *A. medius* (see above) has unequal cleavages, and is probably related to the wallerianite. The grayish to colorless hornblende from Edenville, called by him *Edenite* (see p. 235), he also refers to his genus *Hemiprismatites*.

11. *Aluminous Iron-Lime Amphibole;* NORALITE *Dana.* Color black.

12. *Aluminous Iron-Manganese Amphibole;* GAMSIGRADITE *Breith.* (B. H. Ztg., xx. 51, 1861). Color velvet-black. G.=3·12. Named from the locality, Gamsigrad in Servia, where it forms with white feldspar a rock called *timazyte*.

Mangan-amphibol of Hermann (Cummingtonite *Rammelsberg*, and Hermannite *Kenngott*) is nothing but rhodonite of Cummington, Mass., erroneously analyzed.

I. CONTAINING LITTLE OR NO ALUMINA.

1. *Tremolite: Magnesia-Lime Amphibole.* Analyses: 1, 2, Bonsdorff (Schw. J., xxxi. 414, xxxv. 123); 3, Michaelson (Œfv. Ak. Stockh., 1863, 196); 4, Damour (Ann. Ch. Phys., III. xvi.); 5, Richter (Pogg., lxxxiv. 353); 6, Rammelsberg (Pogg., ciii. 295); 7, Lechartier (Bull. Soc. Ch., II. iii. 381); 8, 9, Rammelsberg (l. c.); 10, Beudant (Ann. d. M., II. v. 307); 11, Rammelsberg (l. c.); 12, id. (J. pr. Ch., lxxxvi. 347).

2. *Actinolite: Magnesia-Lime-Iron Amphibole.* 13, Bonsdorff (l. c.); 14, Seybert (Am. J. Sci., vi. 333); 15, Hunt (Am. J. Sci., II. xii, 213, Phil. Mag., IV. i. 322); 16, Furuhjelm (Arppe, Undersökn, p. 69, Ramm. Min. Ch., 471); 17, 18, Rammelsberg (l. c.); 19, Richter (l. c.); 20, Pipping (Berz. Jahresb., xxvii. 252); 21, v. Merz (Viert. Ges. Zurich, 1861, Kenng., 1860); 22, Schwalbe (ib., vii. 20, Kenng., 1861, 68; 23, Michaelson (Œfv. Ak. Stockh., 1863, 199); 24, Murray (Ramm. 2d Suppl., 60); 25, Bonsdorff (l. c.); 26, Rammelsberg (1st Suppl., 73); 27, Meitzendorf (Pogg., lii. 626); 28, Scheerer (Pogg., lxxxiv. 331); 29, Richter (ib.); 30, Scheerer (l. c.).

3. *Antholite: Magnesia-Iron Amphibole.* 31, Thomson (Rec. Gen. Sci., xvii); 32, Beck (This Min., 1850, 692); 33, Lappe (Pogg., xxxv. 486).

In anal. 1, G.=3·059; anal. 3, G.=3·104; anal. 6, G.=3·123; anal. 7, G.=3·102, $I \wedge I$=124° '−124° 12'; anal. 8, called grammatite; anal. 9, G.=3·054, High Falls of the Madawaska, Can.; anal. 14, G.=3·059; 15, from near Kongsberg; anal. 16, G.=3·136; anal. 21, in basalt; 22, in trachyte; anal. 26, G.=3·114, in syenite; anal. 29, G.=3·282, in a block from Somma; anal. 30, G.=3·270, in basaltic tufa; anal. 31, G.=3·225, in basaltic wacke; anal. 32, G.=3·277; anal. 33, G.=3·266, in trachyte; anal. 34, G.=3·214; anal. 35, G.=3·215; 36, in diorite; anal. 37, G.=3·276; anal. 38, G.=3·378; anal. 39, 40, G.=3·287, $I \wedge I$=124° 7′, in zircon-syenite; anal. 41, G.=3·28, in zircon-syenite; anal. 48, G.=3·428, often called Ægirine; anal. 49, G.=3·25, with magnetite; anal. 51, from euphotide of Alps; anal. 52, from euphotide of Finmalto, Corsica, G.=3·10.

In the Vesuvius amphibole (*syntagmatite* Breith.) Mitscherlich found F̶e 9·96 and Ḟe 19·30; in the Härtlingen, respectively, 6·63 and 6·45; in the Wolsberg 13·25 and 2·59; in the Arendal, 5·69 and 14·65.

The *smaragdite* of Corsica afforded Vauquelin, in an imperfect analysis (Beud. Min., ii. 134), S̈i 50·0, A̶l 21·0, Ṁg 6·0, Ċa 13·0, oxyd of iron 5·5, C̶r 7·5, Ċu 1·5=104·5

An *actinolite rock* from St. Francis, Canada, afforded T. S. Hunt (Rep. G. Can., 1863, 466) $\ddot{S}$ 52·30, $\bar{\bar{A}}l$ 1·30, $\dot{M}g$ 21·50, $\dot{C}a$ 15·00, $\dot{F}e$ 6·75, $\dot{N}i$ *tr.*, ign. 3·10=99·95.

The *Byssolite* of Saussure, Dauphiny, as analyzed by Vauquelin and Macquart (J. Soc. Philom., No. 54), afforded $\ddot{S}i$ 47, $\bar{\bar{F}}e$ 20, $\bar{\bar{M}}n$ 10·0, $\dot{M}g$ 9·3, $\dot{C}a$ 11·3=95·6. Occurs with a black oxyd of manganese.

The analysis by Thomson (Ann. Lyc. N. H. N. York, iii. 50), referred by Shepard to *boltonite*, is shown by B. Silliman, Jr. (Am. J. Sci., II. viii. 391), to pertain probably to an actinolite from Bolton.

The fluorine in many hornblendes is supposed to exist as fluorid of calcium, and this ingredient, according to Bonsdorff, may constitute 1 part in 5 of the mineral.

Pyr., etc.—The observations under pyroxene apply also to this species, it being impossible to distinguish the varieties by blowpipe characters alone.

Isomorphous and Dimorphous relations to Pyroxene.—The analogy in composition between pyroxene and hornblende has been abundantly illustrated. They have the same general formula; and under this formula there is but one difference of any importance, viz., that lime is a prominent ingredient in *all* the varieties of pyroxene, while it is wanting, or nearly so, in some of those of hornblende.

The analogy between the two species in crystallization, or their essential isomorphism, was pointed out by G. Rose in 1831, who showed that the forms of both were referrible to one and the same fundamental form. The prism *I* of hornblende corresponds in angle to *i*-2 of pyroxene; that is, if the horizontal axes of the latter species be *b*: *c*, those of the former will be *b*: 2*c*. Calculating from the angle *I* ∧ *I* in pyroxene, 87° 5′, the angle of *i*-2 is precisely 124° 30′, or the angle *I* ∧ *I* in hornblende. The annexed table exhibits the symbols of the planes in hornblende as they would be on the augite type.

O				
−1-*i*		−1-2		−1-*i*
			−$\frac{1}{2}$-$\frac{3}{2}$	
i-*i*	*i*-6	*i*-2	*i*-$\frac{3}{2}$	*i*-*i*
2-*i*		2-2		
1-*i*		1-2		1-*i*

But while thus isomorphous in axial relations or form, they are also *dimorphous.* For (1) the cleavage in pyroxene is parallel to the prism of 87° 5′, and in hornblende to that of 124½°. (2) The occurring secondary planes of the latter are in general diverse from those of the former, so that the crystals differ strikingly in habit or system of modifications. Moreover, in pyroxene columnar and fine fibrous forms are uncommon; in hornblende, exceedingly common. (3) The several chemical compounds under pyroxene have *one-tenth* higher specific gravity than the corresponding ones under hornblende; that is, a compound (as, for example, ($\frac{1}{2}\dot{C}a+\frac{1}{2}\dot{M}g)^3\ddot{S}i^2$) having G.=3·28 under the former, has approximately, G.=2·95 under the latter.

Again, twins occur composed part of amphibole and part of pyroxene, a fact bearing on the isomorphism and dimorphism of the species.

Obs.—Amphibole occurs in many crystalline limestones, and metamorphic granitic and schistose rocks, and sparingly in serpentine, and volcanic or igneous rocks. Tremolite, the magnesia-lime variety, is especially common in limestones, particularly magnesian or dolomitic; actinolite, the magnesia-lime-iron variety, in steatitic rocks; and brown, dark-green, and black hornblende, in chlorite schist, mica schist, gneiss, and in various other rocks of which it forms a constituent part. Asbestus is often found in connection with serpentine.

Hornblende-rock, or *amphibolyte*, consists of massive hornblende of a dark greenish-black or black color, and has a granular texture. Occasionally the *green* hornblende, or actinolite, occurs in rock-masses, as at St. Francis, in Canada.

Hornblende-schist has the same composition as amphibolyte, but is schistose or slaty in structure. It often contains a little feldspar. In some varieties of it the hornblende is in part in minute needles.

Diabase is a fine-grained, compact hornblende-rock, tough and heavy.

Aphanyte (or *corneine*) is like diabase, but is without distinct grains (whence the name, from ἀφανής, *unmanifest*), and breaks with a smooth flint-like fracture.

Syenite is a granite-like rock, containing hornblende along with quartz and orthoclase feldspar. *Dioryte* is a similar rock, grayish-white to nearly black in color, consisting of hornblende and albite. *Hornblendic* or *syenitic gneiss* has the same constitution as syenite, but differs in having a gneissoid or semischistose structure.

Hornblendic granite contains hornblende in addition to the ordinary constituents of granite, quartz, feldspar, and mica. *Gneiss* and *mica schist* are often *hornblendic* in the same way. The hornblende in mica schist is usually in prisms, either stout or acicular, which sometimes are aggregated in sheaf-like tufts. The *fasciculite* of Hitchcock is merely this tufted hornblende.

The dark-green antique porphyry contains hornblende in its compact, diabase-like mass, and is therefore called *diabase-porphyry.* G.=2·9—3·0.

Hornblende is often disseminated in black prismatic crystals through trachyte, and also through other igneous rocks, especially the feldspathic kinds.

Euphotide consists of a whitish or greenish compact base of varying constitution, with imbedded *smaragdite*. The euphotide of Corsica has been called *corsilyte* (p. 235). The *saussurite*, as shown by Hunt (Am. J. Sci., xxviii. 336), is either compact *lime-epidote*, as that of the Alps, compact *meionite*, as that of Mt. Genèvre, or compact *feldspar*; these different kinds being distinguishable by their specific gravity.

The compact tremolite called *nephrite* is found in talcose rock or schist, and granular limestone

Aussig and Teplitz in Bohemia, Tunaberg in Sweden, and Pargas in Finland, afford fine specimens of the dark-colored hornblendes. *Actinolite* occurs at Saltzburg and Greiner in the Zillerthal; *tremolite* at St. Gothard, in granular limestone or dolomite, the Tyrol, the Bannat, Gulsjö in Sweden, etc. *Calamite* occurs at Normarken in Sweden, in prisms in serpentine. *Asbestus* is found in Savoy, Saltzburg, the Tyrol; also in the island of Corsica, where it is so abundant that Dolomieu employed it in packing his minerals. *Rock cork* is obtained in Saxony, Portsoy, and Leadhills, where also mountain leather occurs. Oisans, in France, affords a variety of amianthus, composed of fibres having some degree of elasticity; it is the *amianthoide* of Haüy.

In the United States, in *Maine*, black crystals occur at Thomaston, at Moultenboro in syenite; pargasite at Phipsburg and Parsonsfield; radiated or asbestiform actinolite at Unity; tremolite at Thomaston and Raymond. In *N. Hamp.*, black crystals at Franconia. In *Vermont*, glassy and radiated actinolite in the steatite quarries of Windham, Readsboro', and New Fane. In *Mass.*, white crystals at Lee (1½ m. S.W. of the meeting-house), and at Newberg; glassy and radiated actinolite at Middlefield and Blanford; radiated actinolite at Carlisle, Pelham, Windsor, Lee, and Great Barrington; black crystals at Chester; asbestus at Brighton, Sheffield, Pelham, Newbury, Dedham; cummingtonite at Cummington and Plainfield. In *Conn.*, in large flattened white crystals and in bladed and fibrous forms (tremolite) in dolomite, Canaan, between the Falls and the post-office, and also at other places in Litchfield Co.; asbestus at West Farms, Winchester, and Wilton, and with mountain leather formerly at the Milford serpentine quarries. In *N. York*, in good black crystals at Willsboro', presenting interesting forms; also near the bridge at Potsdam, St. Lawrence Co.; near Greenwood Furnace, and in Warwick, Orange Co. (f. 229); dark green crystals near Two Ponds, and also 1 m. N., 2½ m. N., and 1 m. S., of Edenville, together with gray or hair-brown crystals and tremolite, sphene, and chondrodite, in granular limestone; of various forms and colors, and often in large and perfect crystals, near Amity; in dark green crystals, with ilmenite, at the Stirling mines, Orange Co.; in short green crystals at Gouverneur, sometimes 2 or 3 in. in diameter, along with apatite; in Rossie, 2 m. N. of Oxbow, the variety pargasite in neat bright green crystals; glassy and radiated actinolite near a hamlet called Pecksville, in Fishkill; radiated at Brown's serpentine quarry, 3 m. N.W. of Carmel, Putnam Co.; in large white crystals at Diana, Lewis Co.; radiated and bladed tremolite at Dover, Kingsbridge, the Eastchester quarries, Hastings, and near Yonkers, in Westchester Co.: at Knapp's quarry, Patterson, in Putnam Co., and on the banks of Yellow lake and elsewhere in St. Lawrence Co.; asbestus, near Greenwood Furnace; Rogers's farm in Patterson; Colton rock and Hustis's farm in Phillipstown, Putnam Co.; near the Quarantine in Richmond Co., where the fibres are two to three feet long. In *N. Jersey*, tremolite or gray amphibole in good crystals at Bryam, and other varieties of the species at Franklin and Newton; radiated actinolite at Franklin; tremolite at Franklin; asbestus and mountain leather at Brunswick. In *Penn.*, actinolite in Providence, at Mineral Hill, in Delaware Co.; at Unionville; at Kennott, Chester Co., often in fine crystals; tremolite with asbestus at Chestnut Hill near the Wissahiccon, near Philadelphia, at London Grove, Chester Co.; nephrite at Easton. In *Maryland*, actinolite and asbostus at the Bare Hills in serpentine; asbestus at Cooptown. In *Virginia*, actinolite at Willis's Mt., in Buckingham Co.; asbestus at Barnet's Mills, Fauquier Co.

Alt.—The alterations of amphibole are similar to those of pyroxene (see page 220). The fibrous and diallage-like varieties are especially liable to take up water, owing to the finely or thinly divided state of the mineral. Talc, steatite, serpentine, chlorite, biotite, pinite, chabasite, limonite, magnetite, iron ochre, are among the reported results of alteration.

At Ilmenau, a magnesia-mica, a chlorite, and also (as an after product from the chlorite) iron-ochre, occur as pseudomorphs after hornblende (v. Fritsch, ZS. Geol. Ges., xii. 104). *Groppite*, and perhaps *rosite*, as suggested to the author by L. Sæmann (4th edit., p. 287), may be altered pargasite. Genth describes the asbestiform or fibrous serpentine of Texas and Providence, Pa., and the *baltimorite* as altered asbestus, and a chrysolite of Delaware Co., Pa., as altered actinolite (Am. J. Sci., II. xxxiii. 203).

The following are analyses of altered amphiboles: 1, Smith & Brush (Am. J. Sci., II. xvi. 49); 2, Thomson (Min., i. 209); 3, C. A. Joy (Ann. Lyc. N. H. N. Y., viii. 123); 4, 5, Beck (Min. N. Y., 307); 6, Suckow (Die Verwitt. Min., 143); 7, Delesse (Ann. d. M., IV. x. 317); 8, Wiehage (Ramm. Min. Ch., 499); 9, Madrell (Pogg., lxii. 142); 10, Schultz (Ramm. Min. Ch., 499); 11, T. S. Hunt (Phil. Mag., IV., ii. 65, and Rep. G. Can. 1863, 491):

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
1. *Hyd. anthophyllite*, N.Y.	58·38	*tr.*	8·76	—	29·34	—	0·88	2·26, $\dot{\mathrm{K}}$ *tr.*=99·57 S.&B

10. Catançaro	46·08	11·81	14·10	—	10·72	8·74	0·93	3·03, $\bar{\mathrm{Fe}}$ 1·77=98·88 S.
11. *Loganite*	33·28	13·30	$\bar{\mathrm{Fe}}$ 1·92	—	35·50	—	—	16·00=100 T. S. Hunt.

Anal. 4, 5, crystals having the angles of hornblende, steatitic in feel and hardness; 6, clay-like; 7, from a micaceous porphyry at Traits-de-Roche, small prisms; 8. from trachyte at Margarettenkreuz; 9, large crystals, G.=2·94, from Wolfsberg, near Cernosin in Bohemia; 10, soft greenish-brown crystals; 11, associated with pale-green serpentine, phlogopite, and apatite, in Laurentian crystalline limestone, and having the form and cleavage of hornblende, though edges rounded; *I* ∧ *I* about 124°.

The *hydrous anthophyllite* of New York Island occurs in place near the corner of 59th street and 10th avenue, and also in many places in boulders. The variations in the analyses, as well as in the aspect of the material, show that it is a result of the alteration of an asbestiform tremolite.

247A. WALDHEIMITE. (Amphibol ähnliches Min. von Waldheim *A. Knop*, Ann. Ch. Pharm., cx. 363, 1859; Waldheimit *Ramm.*, Min. Ch., 780, 1860.) An amphibole-like mineral, which contains much *soda*, and is peculiar also in its excess of silica, both suggesting that it may be amphibole altered by the alkaline process. It occurs in veins an inch thick, and resembles actinolite. H.=5; G.=2·957; color leek-green; translucent. Composition, according to Knop and Hoffmann, the silica in each being a mean of two determinations (Ann. Ch. Pharm., cx. 363)·

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$
58·71	1·52	5·65	0·25	10·01	11·53	12·38=100·05 Knop.
58·45	1·92	5·53	0·51	11·12	10·28	12·61=100·42 Hoffmann.
58·45	1·74	5·79	0·32	10·83	10·76	12·93=101·12 Hoffmann.

It lost 0·5 p. c. by ignition. The oxygen ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$ is 11·84 : 0·80 : 31·24.

From serpentine at Waldheim in Saxony. The large amount of soda present suggests a relation to arfvedsonite. It is to be observed that the *excess of silica* occurs along with an unusual proportion of *alkali*.

247B. KOKSCHAROFFITE. (Kokscharowit *N. Nordenskiöld*, Bull. Soc. Nat. Moscow, xxx. 223, 1857.) Like tremolite in appearance. *I* ∧ *I*=124°—124° 5′, Kokscharof. In aggregations of prisms, with acute edges replaced. Cleavage: *I*, two, equal, very distinct. H.=5—5·5. G.=2·97. Lustre subadamantine to vitreous. Colorless, dirty-white; brown to dark-brown from impurity. Subtranslucent. Fracture splintery.

An analysis by Hermann (J. pr. Ch., lxxxviii. 197) afforded:

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	ign.
45·99	18·20	2·40	16·45	12·78	1·53	1·06	0·60=99·01

Giving the O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$ 11·19 : 8·50 : 24·52; or, for $\dot{\mathrm{R}}+\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$ 19·69 : 24·52=1 : 1·25; for $\dot{\mathrm{R}}$: $\bar{\mathrm{R}}+\ddot{\mathrm{Si}}$ 11·19 : 33·02. It appears to be, like edenite, a magnesia-lime amphibole, but with a very large proportion of alumina; and, moreover, part of the alumina must be basic if it comes under the usual amphibole formula.

In a closed tube only traces of water. B.B. in the forceps fuses easily to a white translucent pearl, coloring the flame yellow; with borax a clear colorless glass.

Occurs associated with lapis-lazuli near L. Baikal, in Siberia. Named after the Russian mineralogist, Kokscharof.

247C. SCHEFFERITE *Breith.* (B. H. Ztg., xxiv. 429). Breithaupt has referred to schefferite of Michaelson a mineral of the same locality—Longban, with rhodonite—which differs from it widely in composition, if the analyses may be trusted. Moreover, it occurs in crystals, while the true schefferite is known only massive. The following are its characters:

Monoclinic; *I* ∧ *I*=120° 45′; basal plane (*x*) on *i-i*=147° 30′, or 32½° to the axis. The crysta has the planes *I*, *i-i*, *i-i*, the basal plane referred to, and a hemidome on the acute angle in front. Cleavage: rather distinct in one direction, perhaps also parallel to *x*. Mostly massive, fine granular. H.=5—5·5. G.=3·433—3·436. Lustre vitreous. Color chestnut to clove and reddish brown. Streak pale yellowish-gray. Subtranslucent to opaque.

Composition according to Dr. Winkler (l. c.):

$\dddot{\text{Si}}$	$\overline{\text{Al}}$	$\overline{\text{Fe}}$	$\overline{\text{Mn}}$	$\dot{\text{Ni}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{K}}$
49·50	1·42	25·43	6·78	0·20	4·27	7·75	0·19

The iron was ascertained to be all sesquioxyd. The analysis afforded also 3·08 $\dot{\text{Ca}}\ddot{\text{C}}$, and 0·01 $\dot{\text{Mn}}\ddot{\text{C}}$. It requires further study.

248. ARFVEDSONITE. *Brooke*, Ann. Phil., v. 381, 1823. Arfwedsonit. Soda-hornblende.

Probably monoclinic. $I \wedge I = 123°\ 55'$, Brooke; 123° 50′, v. Kobell; 123° 30′, Breithaupt; about 124° 40′, Brevig mineral, Descloizeaux. Cleavage: perfect parallel to I; imperfect to $i\text{-}i$. Also cleavable massive.

H.=6. G.=3·44, Brooke; 3·329—3·340, Breithaupt; 3·589, Rammelsberg. Lustre vitreous. Color pure black; in thin scales, deep green, Greenland, or brown, Brevig. Streak grayish-green. Opaque except in very thin splinters. Fracture imperfectly conchoidal.

Comp.—$2\,\dot{\text{R}}^3\dddot{\text{Si}}^3 + 3\,\overline{\text{Fe}}\,\dddot{\text{Si}}^3$, Ramm., $=(\frac{2}{5}\dot{\text{R}}^3 + \frac{3}{5}\overline{\text{Fe}})\dddot{\text{Si}}^3$, which, making $\dot{\text{R}} = \frac{1}{2}\dot{\text{Fe}} + \frac{1}{2}\dot{\text{Na}}$, =Silica 50·5, sesquioxyd of iron 26·9, protoxyd of iron 12·1, soda 10·5=100. $3\,\dot{\text{R}}^3\dddot{\text{Si}}^3 + 2\,\overline{\text{Fe}}\,\dddot{\text{Si}}^3$, v. Kobell, $=(\frac{3}{5}\dot{\text{R}}^3 + \frac{2}{5}\overline{\text{R}})\dddot{\text{Si}}^3$. Analyses: 1, Thomson (Min., i. 483); 2, v. Kobell (J. pr. Ch., xiii. 3, and xci. 449); 3, Rammelsberg (Pogg., ciii. 292, 306); 4, Plantamour (J. pr. Ch., xxiv. 300):

	$\dddot{\text{Si}}$	$\overline{\text{Al}}$	$\overline{\text{Fe}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	Cl	ign.
1. Greenland	50·51	2·49	35·14	——	7·46	——	1·56	——	——	——	0·96=98·12 T.
2. "	49·27	2·00	14·58	23·00	0·62	0·42	1·50	8·00	*tr.*	0·24	——=98·17 K.
3. "	51·22	*tr.*	23·75	7·80	1·12	0·90	2·08	10·58	0·68	——	0·16=98·29 R.
4. Brevig	46·57	3·41	——	24·38	2·07	5·88	5·91	7·79	2·96, $\ddot{\text{Ti}}$ 2·02=100·99 Pl.		

In the above analyses the degree of oxydation of the iron was determined only in those by Rammelsberg and v. Kobell. A. Mitscherlich has obtained (J. pr. Ch., lxxxvi. 11) for the Greenland A., $\overline{\text{Fe}}$ 25·37, $\dot{\text{Fe}}$ 5·93.

Pyr., etc.—B.B. fuses at 2 with intumescence to a black magnetic globule; colors the flame yellow (soda); with the fluxes gives reactions for iron and manganese. Not acted upon by acids.

Obs.—Occurs in black hornblende-like crystals at Kangerdluarsuk in Greenland, with sodalite, eudialyte, and feldspar; also in zircon-syenite in Norway, at Brevig, and in beds of magnetite at Arendal. Reported also from Horberigberg, near Oberbergen, with ittnerite and ilmenite. The Brevig mineral, analyzed by Plantamour, has been referred to *ægirine*. The angle given determines its relation to the amphibole sub-group.

249. CROCIDOLITE. Blau-Eisenstein (fr. S. Africa) *Klapr.*, Mag. Berl. Ges. N. Fr., v. 72, 1811, Beitr., vi. 237, 1815. Krokydolith *Hausm.*, Gel. Anz. Gött., 1585, 1831. Blue Asbestus.

Fibrous, asbestus-like; fibres long but delicate, and easily separable. Also massive or earthy.

H.=4. G.=3·2—3·265. Lustre silky. Color and streak lavender-blue or leek-green. Opaque. Fibres somewhat elastic.

Comp.—The analyses by Stromeyer afford nearly $\dot{\text{R}}^6\dddot{\text{Si}}^5 + 2\,\dot{\text{H}}$; but the degree of oxydation of the iron is undetermined. Analyses: 1, 2, Stromeyer (Pogg., xxiii. 153); 3, Delesse (Ann. d. M., III. x. 317):

	$\dddot{\text{Si}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{H}}$
1 Africa, *fibrous*	50·81	33·88	0·17	2·32	0·02	7·03	5·58=98·81 Stromeyer.
2 " *earthy*	51·64	34·38	0·02	2·64	0·05	7·11	4·01=99·85 Stromeyer.
3. Vosges	53·02	25·62	$\dot{\text{Mn}}$ 0·50	10·14	1·10	5·69	2·52, $\dot{\text{K}}$ 0·39, Cl 0·51, $\dddot{\text{P}}$ 0·17=99·66

Pyr., etc.—In the closed tube yields a small amount of alkaline water. B.B. fuses easily with intumescence to a black magnetic glass, coloring the flame yellow (soda). With the fluxes gives reactions for iron. Unacted upon by acids.

Obs.—Occurs in South Africa, in the Griqua country, beyond the Great Orange river, 700 m up from the Cape of Good Hope; in a micaceous porphyry at Wakembach in the Vosges (anal. 3); at Stavern, Norway, in zircon-syenite, along with arfvedsonite, to which it is closely related, and of which, as has been suggested, it may be a fibrous or asbestiform variety; at Golling in Salzburg, in gypsum with blue quartz; at Ruka, near Domaschow in Moravia, with a ferruginous dolomite; in Greenland, both fibrous and earthy. In the African, the fibres of the fibrous seams or masses make an angle of about 106° with the opposite surfaces of the seam, according to Hausmann; and the same author states (Handb., 743, 1847) that a cylinder of it $\frac{1}{100}$ of an inch in diameter, supported 91 Hanoverian pounds before breaking, while one of asbestus, $\frac{1}{100}$ of an inch in diameter, broke with a weight of 6 ounces.

The Stavern mineral, referred here by Hausmann, is the Faseriger Siderit *Leonh.*, Gehl. J., iii. 101, and Fasriges Eisenblau *Hausm.*, Handb., 1076, 1813.

Named from κροκις (or κροκός), *woof*, in allusion to its fibrous structure.

250. WICHTISITE. Wichtyne *Laurent*, Ann. Ch. Phys., lix. 107, 1835. Wichtisit *Hausmann*.

Massive; cleavage parallel to the sides of a rhombic prism, nearly rectangular, according to Laurent.

Scratches glass. G.=3·03. Color black. Lustre dull. Fracture angular, or flat conchoidal.

Comp.—$(\frac{1}{2}\dot{\text{R}}^3+\frac{1}{2}\ddot{\bar{\text{R}}})\ddot{\text{Si}}^3$. **Analyses:** 1, Laurent (l. c.); 2, Strömberg (Arppe Finska Min., 17):

$\ddot{\text{Si}}$	$\ddot{\bar{\text{A}}}\text{l}$	$\ddot{\bar{\text{F}}}\text{e}$	$\dot{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$
56·3	13·3	4·0	13·0	3·0	6·0	3·5=99·1 Laurent.
54·24	14·27	—	15·62	3·86	5·65	3·88, $\dot{\text{Mn}}$ 2·70=100·22 Strömborg.

B.B. fuses to a black enamel and becomes magnetic. Not attacked by acids.

From Wichtis in Finland. Dufrénoy observes that a specimen examined by him had no cleavage.

Gmelin has analyzed a mineral from a basaltic rock near Wetterau (Jahrb. Min., 1840, 549), having G.=2·705, and not acted upon by acids, which has essentially the composition of wichtisite, it affording $\ddot{\text{Si}}$ 56·80, $\ddot{\bar{\text{A}}}\text{l}$ 15·32, $\dot{\text{Fe}}$ 12·06, $\dot{\text{Mn}}$ 3·72, $\dot{\text{Ca}}$ 4·85, $\dot{\text{Mg}}$ 5·05, $\dot{\text{K}}$ 0·34, $\dot{\text{Na}}$ 3·14, corresponding closely to $(\frac{1}{2}\dot{\text{R}}^3+\frac{1}{2}\ddot{\bar{\text{A}}}\text{l})\ddot{\text{Si}}^3$. Rammelsberg includes the analysis among those of pyroxene, but speaks of the composition as anomalous; unlike the augites, the alumina does not replace any of the silica.

251. GLAUCOPHANE *Hausmann*, Gel. Anz. Gött., 195, 1845. Orthorhombic or monoclinic. In indistinct long thin six-sided prisms, made up of the planes *I* and *i*-*ī*, and longitudinally striated. Also granular massive. H.=5·5. G.=3·103—3·113. Lustre vitreous to pearly. Color blue, lavender-blue, bluish-black, grayish. Streak-powder grayish-blue. Translucent to opaque. Brittle. Powder slightly magnetic.

Comp.—$(\frac{2}{3}\dot{\text{R}}^3+\frac{1}{3}\ddot{\bar{\text{R}}})\ddot{\text{Si}}^3$. Analysis by Schnedermann (J. pr. Ch., xxxiv. 238):

$\ddot{\text{Si}}$ 56·49 $\ddot{\bar{\text{A}}}\text{l}$ 12·23 $\dot{\text{Fe}}$ 10·91 $\dot{\text{Mn}}$ 0·50 $\dot{\text{Mg}}$ 7·97 $\dot{\text{Ca}}$ 2·25 $\dot{\text{Na}}$ with *tr.* $\dot{\text{K}}$ 9·28=99·63

B.B. becomes yellowish-brown, and melts easily and quietly to an olive-green glass. An iron reaction with the fluxes. In acids partly soluble.

Occurs at the island of Syra, one of the Cyclades, in mica slate, along with garnet, hornblende, and mica. The name is from γλαυκός, *bluish-green*, and φαίνω, *I appear*.

252. SORDAVALITE. Sordawalit *N. Nordenskiöld*, Finl. Min., 86, 1820.

Massive; no cleavage apparent.

H.=2·5. G.=2·53—2·58. Lustre vitreo-resinous, or like bitumen. Streak liver-brown. Color grayish or bluish-black. Opaque. Fracture conchoidal. Brittle.

Comp.—**Analyses:** 1, Nordenskiöld (l. c.); 2, Wandesleben (N. Jahrb. Pharm., i. 32):

	$\ddot{\text{Si}}$	$\ddot{\bar{\text{A}}}\text{l}$	$\dot{\text{Fe}}$	$\dot{\text{Mg}}$	$\ddot{\bar{\text{P}}}$	$\dot{\text{H}}$
1.	49·40	13·80	18·17	10·67	2·68	4·38=99·10 Nordenskiöld.
2.	47·70	16·65	$\ddot{\bar{\text{F}}}\text{e}$ 21·32	10·21	2·26	——=98·14 Wandesleben.

Supposed by Berzelius to be a silicate mixed with some phosphate of magnesia, the silicate corresponding to ($\frac{1}{3}$ ($\dot{M}g$, $\dot{F}e$)^3 + $\frac{1}{3}$ $\ddot{\bar{A}}l$) $\dddot{S}i^2$, which is essentially the formula of wichtisite; but the second analysis makes the iron sesquioxyd.

B.B. alone, it is difficultly fusible to a blackish globule. With borax it forms a green glass. Partly soluble in muriatic acid. Becomes reddish on exposure to the atmosphere.

Forms thin layers on trap, near the town of Sordavala in Finland; at Bodenmais in Bavaria, it is associated with pyrrhotite. It resembles pit-coal in appearance.

253. TACHYLYTE. Tachylyt (fr. Säsebühl) *Breith.*, Kastn. Arch. Nat., vii. 112, 1826.

Massive without cleavage, looking like obsidian or gadolinite. H.=6·5. G.=2·565–2·593. Lustre between vitreous and resinous. Color pitch-black, velvet-black to grayish-black. Brittle. In powder attractable by the magnet.

Comp.—Analysis: Schnedermann (Studien d. G. B. B. Fr., v. 100):

$\dddot{S}i$	$\ddot{\bar{A}}l$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	$\dot{H}$
55·74	12·40	13·06	0·19	5·92	7·28	3·88	0·60	2·73

Pyr., etc.—B.B. fuses easily with intumescence to a brown slag or opaque glass.

Obs.—Found at Säsebühl, between Dransfeld and Göttingen, in basalt and wacke.

Named from ταχύς, *quick*, and λυτός, *dissolved*, in allusion to the fusibility.

253A. HYALOMELAN *Hausm.*, Handb., 545, 1847. Gmelin referred to tachylyte a mineral from a porous volcanic rock in the Vogelsgebirge, to which Hausmann has since applied the name *hyalomelan*. It is similar in aspect, structure, and hardness; G.=2·7144. Gmelin's analysis (Pogg., xlix. 234) afforded:

$\dddot{S}i$	$\ddot{\bar{A}}l$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	$\ddot{T}i$	$\dot{H}$ & Am
50·22	17·84	10·27	0·40	3·37	8·25	5·18	3·87	1·42	0·50=101·32

It affords approximately 3 $\dot{R}$, $\ddot{\bar{A}}l$, 4$\frac{1}{2}$ $\dddot{S}i$. But little reliance can be placed on results with such amorphous minerals. The species may be the same with tachylyte. Hausmann places near here the *slaggy augite* of Karsten, having G.=2·666, from a limestone bed near Guiliana, Sicily, from which Klaproth obtained (Beitr., iv. 190) $\dddot{S}i$ 55·00, $\ddot{\bar{A}}l$ 16·50, $\ddot{\bar{F}}e$ 13·75, $\ddot{\bar{M}}n$ *tr.*, $\dot{M}g$ 1·75, $\dot{C}a$ 10·00, $\dot{H}$ 1·50.

A similar mineral in appearance is found on the north shore of Lake Superior; and also in a trap dike at Johnsburg, Warren Co., N.Y.

254. BERYL. Σμάραγδος pt. [rest Chrysocolla, Malachite, etc., and other green stones] *Theophr.* Βήρυλλος *Gr.* Smaragdus pt. [rest as above] + Beryllus (Chrysoberyllus, Chrysoprasius incl.) *Plin.*, xxxvii. 16–20. Emerald; Beryl; Aquamarine. Smaragdus + Beryll *Wall.*, Min., 117, 122, 1747. Smaragdus + Bloagrön Topas (=Beryll, Aquamarin) *Cronst.*, Min., 44, 1758. Emeraude (incl. Emerald and Beryl or "Aigue-marine," and Chrysolite du Brésil) *de Lisle*, Crist., 135, 1772, ii. 245, 1783; *H.*, J. d. M., iv. 72, 1798, Tr., ii. 1801. Schmaragd + Beril *Wern.*, the two as distinct sp. until 1811. A silicate of alumina with lime *Achard*, Edelst., 47, 1779; *Bergm.*, Opusc., ii. 96, 1782; and others. A silicate of alumina and GLUCINA *Vauq.*, J. d. M., iv., 1798, vii. 97, 1800; *Klapr.*, Beitr., iii. 221, 1802. Davidsonite (fr. near Aberdeen) *Thomson*, Min., i. 247, 1836. Goshenite *Shep.*, Min., i. 143, 1844.

Hexagonal. $O \wedge 1 = 150° 3'$; $a = 0·499$. Occurring planes: O; vertical, I, i-2, i-$\frac{3}{2}$; hexag. pyramids, 1, $\frac{3}{2}$, 2, $\frac{15}{2}$; 1-2, 2-2; dihexag. pyr., in zone 2-2: I, 3-$\frac{3}{2}$, 4-$\frac{4}{3}$, 12-$\frac{12}{11}$; id. in other zones, 2-$\frac{3}{2}$, 2-$\frac{8}{7}$, 6-$\frac{3}{2}$, 14-$\frac{4}{3}$.

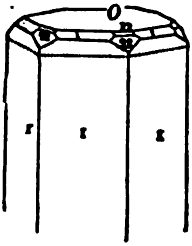
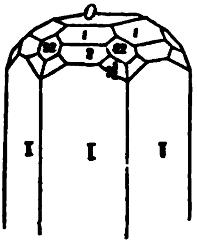
$O \wedge 3\text{-}\frac{3}{2} = 123 \ 16$	$I \wedge I = 120$	$I \wedge 8\text{-}\frac{8}{7} = 165 \ 30$

231



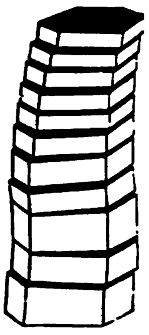
Haddam, Ct.

232



Siberia.

233



Monroe, Ct.

Cleavage: basal imperfect; lateral indistinct. Occasionally coarse columnar and large granular.

H.=7·5—8. G.=2·63—2·76. Lustre vitreous, sometimes resinous. Color emerald-green, pale green, passing into light-blue, yellow, and white. Streak white. Transparent—subtranslucent. Fracture conchoidal, uneven. Brittle. Double refraction feeble; axis negative.

Var.—This species is one of the few that occur only in crystals, and that have no essential variations in chemical composition. There are, however, two prominent groups dependent on color, the color varying as chrome or iron is present; but only the merest trace of either exists in any case. The crystals are usually oblong prisms.

1. *Emerald.* Color bright emerald-green, owing to the presence of chromium. G.=2·67, fr. Muso, Lewy; 2·63, fr. Pinzgau, Hofmeister; 2·710—2·759, fr. Ural, Kammerer. Hardness a little less than for beryl, according to the lapidaries.

2. *Beryl.* Colors those of the species, excepting emerald-green, and due mainly to iron. G.=2·694—2·695, transparent, colorless, fr. Ural; 2·681—2·694, id., yellowish, id.; 2·702—2·710, id., green, id.; 2·725, id., rose-red, id.; all by Kokscharof. On cryst., see Kokscharof, Min. Russl., i. 147, ii. 356, iii. 72, iv. 125; Hessenberg, Min. Not., v. 28. The varieties of beryl depending on color are of importance in the arts, when the crystals are transparent enough to be of value as gems. The principal kinds are: (*a*) colorless; (*b*) bluish-green, called *aquamarine*, a name suggested, though not used, by Pliny, where he says of it, "qui viriditatem puri maris imitantur;" (*c*) apple-green; (*d*) greenish-yellow to iron-yellow and honey-yellow (apparently *chrysoberyllus* of Pliny and ancient jewelry); (*e*) pale yellowish-green (probably the *chrysoprasius* Plin., and perhaps his *chrysolithus* in part, as also in more modern times); (*f*) clear sapphire-blue (*hyacinthozontes* of Plin.); (*g*) pale sky-blue (*aeroïdes* Plin.); (*h*) the pale violet or reddish (*améthiste basaltine* Sage, Min., 231); (*i*) the opaque brownish-yellow, of waxy or greasy lustre. The above names by Pliny are mentioned in his account of beryl. The *oriental emerald* of jewelry is emerald-colored sapphire. *Davidsonite* is nothing but greenish-yellow beryl from near Aberdeen; and *goshenite* is a colorless or white variety from Goshen, Mass. (anal. 16).

Comp.—$(\frac{1}{2}\dot{\mathrm{B}}\mathrm{e}^3+\frac{1}{2}\ddot{\mathrm{A}}\mathrm{l})\ddot{\mathrm{S}}\mathrm{i}^2$=Silica 66·8, alumina 19·1, glucina 14·1=100. Analyses: 1, Dumenil (Schw. In anal. 10, G.=2·65; anal. 13, G.=2·686, from Sheskina-roan in Donegal Co.

The union of emerald and beryl in one species, which Pliny says was suggested in his time, was first recognized on crystallographic grounds by De Lisle, and more satisfactorily through measurements of angles by Haüy; and chemically by Vauquelin.

Pyr., etc.—B.B. alone unchanged or becomes clouded; at a high temperature the edges are rounded, and ultimately a vesicular scoria is formed. Fusibility=5·5 (Kobell). Glass with borax, clear and colorless for beryl, a fine green for emerald. Slowly soluble with salt of phosphorus without leaving a siliceous skeleton. A yellowish variety from Broddbo and Finbo yields with soda traces of tin. Unacted upon by acids.

According to Lewy, the emerald of Muso becomes white at a red heat, and loses, as a mean result, 1·66 of water and 0·12 of organic matter, the latter consisting of 0·03 to 0·05 of hydrogen and 0·09 to 0·06 of carbon.

Obs.—Emeralds occur in clay slate, in isolated crystals or in nests (not in veins), near Muso, etc., 75 m. N.N.E. of Bogota, N. Granada, a rock containing Cretaceous fossils in its limestone* concretions. A perfect hexagonal crystal from this locality, 2 in. long, is in the cabinet of the Duke of Devonshire; it measures across its three diameters 2¼ in., 2⅛ in., 1⅞ in., and weighs 8 oz. 18 dwts.; owing to flaws, it is but partially fit for jewelry. Emeralds of less beauty, but much larger, occur in Siberia, on the river Tokowoia, N. of Katherinenberg, along with phenacite, chrysoberyl, apatite, rutile, etc., imbedded in mica schist. One specimen in the Royal collection measures 14¼ in. long and 12 broad, and weighs 16¾ lbs. troy; another is 7 in. long and 4 broad, and weighs 6 lbs. troy. Mount Zalora, in Upper Egypt, affords a less distinct variety, and was the only locality which was known to the ancients. Occurs about Heubachthal in Salzburg, in mica schist.

Transparent beryls are found in Siberia, Hindostan, and Brazil. In Siberia they occur at the emerald mine mentioned, at Mursinka and Schaitanka, near Katherinenberg; near Miask with topaz; in the mountains of Adun-Tschilon with topaz, and elsewhere; in Hindostan at Canjargum; and in Brazil on Rio San Matteo. Some Siberian transparent crystals exceed a foot in length. The most splendid aquamarine of which we have any account belongs to Don Pedro, and is from Brazil; it approaches in size, and also form, the head of a calf, and exhibits a crystalline structure only on one side; the rest is water-worn; and it weighs 225 oz. troy, or more than 18¾ lbs.; the specimen is transparent and without a flaw. Beautiful crystals also occur at Elba; the tin mines of Ehrenfriedersdorf in Saxony, and of Schlackenwald in Bohemia. Other localites are, the Mourne Mts., Ireland, Co. of Down; also Killiney near Dublin; yellowish-green at Rubislaw, near Aberdeen, Scotland (davidsonite), and elsewhere in Aberdeenshire; in small bluish crystals at St. Michael's Mount in Cornwall; Limoges in France; Finbo and Broddbo in Sweden; Tamela and Somero in Finland; Fossum in Norway; Pfitscher-Joch, Tyrol; Bodenmais and Rabenstein in Bavaria; in Australia, and elsewhere.

---

* Lewy found the limestone to consist of $\dot{\mathrm{Ca}}\ddot{\mathrm{C}}$ 47·8, $\dot{\mathrm{Mg}}\ddot{\mathrm{C}}$ 16·7, $\dot{\mathrm{Mn}}\ddot{\mathrm{C}}$ 0·5, $\ddot{\mathrm{Si}}$ 24·4, $\bar{\bar{\mathrm{Al}}}$ 5·5, $\bar{\mathrm{Be}}$ 3·4, $\dot{\mathrm{Fe}}$ 2·6, pyrite 0·6, alkali 2·7=101·2.

Beryls of gigantic dimensions have been found in the United States, in *N. Hamp.*, at Acworth and Grafton, and in *Mass.*, at Royalston; but they are mostly poor in quality. One beryl from Grafton weighs 2,900 lbs.; it is 32 in. through in one direction and 22 in another transverse, and is 4 f. 3 in. long. Another crystal from this locality, according to Prof. Hubbard, measures 45 in by 24 in its diameters, and a single foot in length by calculation weighs 1,076 lbs., making it in al nearly 2½ tons. At Royalston, one crystal exceeded a foot in length; the smaller crystals are often limpid, and a yellowish variety forms a gem resembling chrysolite; the colors are mostly aquamarine, grass-green, and yellowish-green; one locality is in the southeast part of Royalston, near the school-house, on the land of Mr. Clarke; the best crystals are imbedded in quartz; a still better is situated 4 m. beyond the old one in South Royalston; some crystals of a sky-blue color in white quartz are beautiful.

Other localities are in *Maine*, at Albany; at Norway; Bethel; Hebron; in Paris, large, with black tourmaline and mica; at Bowdoinham and Topham, pale green or yellowish-white, in veins of graphic granite; at Georgetown, Parker's island, mouth of Kennebec. In *N. Hamp.*, at Wilmot; at Compton, as good as at Royalston. In *Mass.*, at Barre, excellent specimens; at Pearl Hill in Fitchburg, at Goshen (goshenite), and at Chesterfield. In *Conn.*, at Haddam, in a feldspar vein in gneiss, on the east side of the river, the crystals having the terminations for a twelfth of an inch transparent (fig. 231, the dotted line indicating the limit of the transparent portion); also at the chrysoberyl locality; the Middletown feldspar quarry; in Chatham, near the cobalt mine, in granite; at Monroe, in a granite vein, the crystals often consisting of displaced pieces separated by quartz (fig. 233); at Madison, in beautiful crystals. In *Penn.*, at Leiperville and Chester, crystals sometimes 10 to 12 in. long and 1½ in diameter, with black tourmaline; at Mineral Hill.

Kokscharof obtained from Ural beryls for the angle $O \wedge 1$, 150° 3′ 24″.

The species *dioptase* and *pyrosmalite* are homœomorphous with beryl, and have the same oxygen ratio between the bases and silica, if the water and chlorine be excluded.

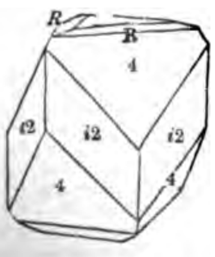
Alt.—Kaolin, mica, limonite, and quartz, occur as pseudomorphs after beryl, the last two by substitution, the others by alteration.

The change to kaolin is the same essentially as in feldspar. An altered beryl, from Tirschenreuth afforded H. Müller (J. pr. Ch., lviii. 182) $\ddot{S}i$ 58·8, $\ddot{\bar{A}}l$ 24·7, $\bar{F}e$ 2·6, $\dot{\bar{B}}e$ 10·2, $\dot{H}$ 2·5. Another, from Vilate, near Chanteloube, gave Damour (Bull. G. Fr., II. vii. 224) $\ddot{S}i$ 45·61, $\ddot{\bar{A}}l$ 38·86, $\bar{F}e$ 0·94, $\dot{\bar{B}}e$ 1·10, $\dot{H}$ 14.04=100·55, corresponding to the common kaolin formula $\ddot{\bar{A}}l\,\ddot{S}i^2+2\dot{H}$.

255. EUDIALYTE. Eudialyt *Stromeyer*, Gel. Anz. Gött. 1819, 1998. Eudyalite *improper orthography*. Eukolit *Scheerer*, Pogg. lxxii. 561, 1847. Eucolite.

Rhombohedral. $R \wedge R$=126° 25′, $O \wedge R$ (or 1)=148° 38′, a=0·52793. Observed planes: O; prisms, I, i-2; rhombohedrons, 1 (or R), $\frac{1}{4}$, 4, −8, −2, $-\frac{1}{2}$; pyramid, $\frac{2}{3}$-2; scalenohedrons, 4^2, 4^3.

234



235

Damour obtained for the oxygen ratio of $\dot{R}$, $\bar{R}$, $\ddot{Si}$ in both eudialyte and eucolite (the $\ddot{Ta}$ being included with the $\ddot{Si}$, and the $\bar{Ce}$ with the $\ddot{Zr}$ as sesquioxyd), 2 : 1 : 6, corresponding to the above formula.

Pyr., etc.—In the closed tube affords water. B.B. fuses at 2·5 to a light green opaque glass, coloring the flame yellow (soda). With the fluxes gives reactions for iron and manganese. With muriatic acid gelatinizes, and the dilute acid solution imparts a deep orange to turmeric paper even after the iron in solution has been reduced to colorless protochlorid by boiling with metallic tin (reaction for zirconia).

Obs.—Eudialyte found at Kangerdluarsuk, n West Greenland, associated with arfvedsonite and sodalite, or imbedded in compact white feldspar; the crystals are usually small, but sometimes an inch or more in length. First named Grönlandischer Hyazinth by Trommsdorff, Crell's Ann. i. 433, 1801.

Eucolite is from islands of the Langesund fiord in Norway, where it occurs in hexagonal prisms and reniform masses. Eudialyte has been reported as occurring at Magnet Cove, in Arkansas, in imperfect rounded crystals, of a rich crimson to peach-blossom-red color, in feldspar, with elæolite (Shepard).

On cryst see B. & M.; also Lang., Phil. Mag., IV. xxv. 436, from whose paper fig. 235 is copied.

The name, from *εὖ, easily*, and *διαλύω, to dissolve*, alludes to its easy solubility in acids. Discovered by C. Giesecke; called Grönlandischen Hyazinth by Trommsdorff in Crell's Ann., i. 433.

---

266. POLLUCITE. Pollux *Breith.*, Pogg., lxix. 439.

Isometric. Cubic, with trapezohedral planes, like analcime. Cleavage: in traces. Massive.

H.=6·5. G.=2·901. Lustre vitreous and bright on surface of fracture, but sometimes dull and gum-like externally. Colorless. Transparent. Index of refraction for the red rays 1·515, blue 1·527; no double refraction; Descl.

Comp.—Probably ($\dot{R}^3$, $\bar{Al}$) $\ddot{Si}^3+\frac{1}{2}\dot{H}$, in which $\dot{R}$=cæsium mainly, and $\dot{R}^3$: $\bar{Al}=1:2\frac{1}{2}$. Analysis: Pisani (C. R., lviii., 714):

$\ddot{Si}$	$\bar{Al}$	$\bar{Fe}$	$\dot{Ca}$	$\dot{Cs}$	$\dot{Na}$, $\dot{Li}$	$\dot{H}$
44·03	15·97	0·68	0·68	34·07	3·88	2·40=101·71

giving the oxygen ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$, 3·16 : 7·68 : 23·48 : 2·13. Plattner obtained (Pogg., lxix 443), before the discovery of cæsium, $\ddot{Si}$ 46·20, $\bar{Al}$ 16·39, $\bar{Fe}$ 0·86, $\dot{K}$ 16·51, Na (with a little $\dot{Li}$), 10·43, $\dot{H}$ 2·32=92·75; and Brush shows (Am. J. Sci., II. xxxviii. 115) that if the cæsium were mistaken for potash, it would give 35·69 $\dot{Cs}$, and reduce the soda (if obtained by difference) to 1·72 p. c., and that thus the results are as close to Pisani's as could be expected, considering the amount of material used. Plattner's analysis thus changed would read $\ddot{Si}$ 46·20, $\ddot{\bar{Al}}$ 16·39, $\ddot{\bar{Fe}}$ 0·86, $\dot{Cs}$ 35·69, $\dot{Na}$ 1·72, $\dot{H}$ 2·32=103·18.

Pyr., etc.—In the closed tube becomes opaque and yields water. In the forceps whitens, fuses with difficulty, coloring the flame yellow. In muriatic acid slowly decomposes, with a separation of pulverulent silica; and the filtrate from the silica gives an abundant precipitate of the platin-chlorid of cæsium when treated with bichlorid of platinum.

Obs.—Occurs in the island of Elba, with petalite (castorite). Named from Pollux (the genitive of which is Pollucis), of heathen mythology.

II. UNISILICATES.

ARRANGEMENT OF THE SPECIES.

A. Unisilicates of elements mostly in the protoxyd (or alpha) state.

1. CHRYSOLITE GROUP. Orthorhombic; I ∧ I=91°—95°: O ∧ 1-ĭ=124°—129°

		Ratio.

Appendix. 317. **Eulytite.** 318. **Atelestite.**

In the preceding table the column of ratios contains the oxygen ratios for the *protoxyds* and *silica* or the *deutoxyds* and *silica*, where no sesquioxyd bases are present, as in the first, second, and third groups, and species 282; for the *protoxyds*, *sesquioxyds*, and *silica*, where the bases include elements in each of these three states, as in all the other groups. In species 285, the ratio is for the protoxyds, sesquioxyds, tritoxyds, and silica.

The letter r (species 268, 287, 298, etc.) signifies oxygen ratio between the bases and silica. This ratio is stated only when the silica is in excess above that of the unisilicate type, and it exhibits the amount of that excess. Q is used in the second column of formulas for any accessory constituents not silica; its value in each case may be derived from the part of the corresponding formula in the first column which is in brackets. In species 265 it stands for $(\dot{F}e, \dot{M}n)\overset{\cdots}{C}b$ in 284B, for $\overset{\cdots}{F}e\dot{\dot{H}}$; and so on.

Examples of an excess of silica occur in many of the above groups; namely, the Chrysolite group, in leucophanite; Phenacite group, in meliphanite; the Epidote group, in jadeite and perhaps in saussurite; the Iolite group; the Mica group, in muscovite, lepidolite, and cryophyllite; Scapolite group, in wernerite, ekebergite, mizzonite, dipyre, marialite; Nephelite group; Leucite group, in leucite; Feldspar group, in all the species excepting anorthite.

It has been shown that this excess of silica is often connected directly with the alkaline nature of the base, and increases with increased alkalinity, as if the former were determined by the latter. The following are the ratios between the non-alkaline and alkaline portions of the base in the above mentioned groups, as decided from the mean of the analyses, together with the ratios for the bases and silica:

		Bases : Silica	Non-alk. Alk.
CHRYSOLITE GR.—	Chrysolite, etc.	1 : 1	all non-alk.
	Leucophanite	1 : 1⅓	4⅓ : 1
PHENACITE GR.—	Phenacite, etc.	1 : 1	all non-alk.
	Meliphanite	1 : 1⅓	6 : 1
EPIDOTE GR.—	Epidote	1 : 1	all non-alk.
	Zoisite	1 : 1	all non-alk.
	Saussurite	1 : 1⅓	6 : 1
	Jadeite	1 : 2	1 : 2
MICA GR.—	Astrophyllite	1 : 1	6 : 1
	Phlogopite	1 : 1	8 : 1
	Biotite	1 : 1	3 : 1
	Lepidomelane	1 : 1	2—1 : 1
	Muscovite	1 : 1½	1 : 2—6
	Lepidolite	1 : 1⅓	1 : 3—12
	Cryophyllite	1 : 2	1 : 2⅓
SCAPOLITE GR.—	Sarcolite	1 : 1	9 : 1
	Meionite	1 : 1	10 : 1
	Paranthite	1 : 1	all non-alk.
	Wernerite	1 : 1⅓	4 : 1
	Ekebergite	1 : 1½	2⅓ : 1
	Mizzonite	1 : 1¾	
	Dipyre	1 : 2	1 : 1
	Marialite	1 : 2 (or 2⅓)	1 : 2
NEPHELITE GR.—	Nephelite	1 : 1⅛	
LEUCITE GR.—	Sodalite	1 : 1	all *soda*.
	Leucite	1 : 2	all *potash*.
FELDSPAR GR.—	Anorthite	1 : 1	all non-alk.
	Labradorite	1 : 1½	2 : 1
	Hyalophane	1 : 2	1⅓ : 1
	Andesite	1 : 2	1 : 1
	Oligoclase	1 : 2¼	1 : 2
	Albite	1 : 3	all alk.
	Orthoclase.	1 : 3	all alk.

In each of the groups in this table the increase in the proportion of silica is accompanied with an increase in the proportion of alkalies. Iolite is an exception, as it contains, according to the analyses hitherto made, no alkalies. Sphenoclase (No. 275) is another, but the mineral is uncrystallized, and it is too little known to be considered in this connection.

The two formulas *a* and *b*, for the species containing this excess of silica, are those explained on page 204, the *first* making the excess *accessory* silica, the *second* making *half* of the excess *basic*.

In connection with the descriptions of the species beyond, only the formulas of the first of the two kinds are given in full.

257. FORSTERITE. *Levy*, Ann. Phil. II., vii. 59, 1824. Peridoto bianco *Scacchi*, Distrib. Sist. Min., 63, Napoli, 1842. White Olivine. Boltonite *Shep.*, Min., i. 78, 1835.

Orthorhombic. Form and angles as in chrysolite. Observed planes: *O*; vertical, *i*-ī, *i*-ĭ, *I*, *i*-2̆, *i*-$\breve{\frac{3}{2}}$, *i*-$\breve{\frac{5}{4}}$; domes, 1-ī, 1-ĭ, $\frac{1}{2}$-ĭ; octahedral, 1, 1-2, $\frac{3}{2}$-$\breve{\frac{3}{2}}$. Cleavage: *i*-ĭ and *O*. In attached crystals. Also in imbedded imperfect crystals, grains, or masses.

H.=6—7. G.=3·21—3·33. Lustre vitreous. Transparent—translucent. Color white, yellowish-white, wax-yellow, grayish, bluish-gray, greenish; sometimes becoming yellowish on exposure when not in distinct crystals. Streak uncolored.

Var.—1. *Forsterite*, white crystals from Vesuvius, H.=7; G.=3.243, Rammelsberg. 2. *Boltonite*, imbedded mineral of other tints, from Bolton, etc., Mass.; H.=6—6·5, G.=3.208—3·328, Smith; 3·21, Breith.

Comp.—$\dot{\text{Mg}}^2\ddot{\text{Si}}$=Silica 42·86, magnesia 57·14=100. Analyses: 1, Rammelsberg (Pogg., cix. 568); 2, J. L. Smith (Am. J. Sci., II. xviii. 372); 3, G. J. Brush (ib., xxvii. 395):

	$\ddot{\text{Si}}$	$\overline{\ddot{\text{Al}}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Fe}}$	ign.	
1. *Forsterite*	42·41	——	53·30	——	2·38	——	= 98·04 Ramm.
2. *Boltonite* ($\frac{1}{2}$)	42·31	0·17	51·16	——	2·78	1·90	= 98·32 Smith.
3. "	42·82	*tr.*	54·44	0·85	1·47	0·76	=100·34 Brush.

Pyr., etc.—B.B. unaltered and infusible. Boltonite gives traces of moisture in the closed tube and becomes colorless. Decomposed by muriatic acid with separation of gelatinous silica in both forsterite and boltonite.

Obs.—Forsterite occurs in implanted crystals, with spinel and augite at Vesuvius. Boltonite is disseminated through a whitish crystalline limestone, at Bolton, Mass.; also at Roxbury and Littleton, Mass.; its imbedded masses or crystals are often over an inch through, and rectangular in section. Part of the boltonite is altered, and thence softer and hydrous, with the composition of villarsite (p.—).

On cryst., B. & M., Min., 318; Hessenberg, Min. Not., No. I., 22.

Forsterite was named by Levy after Mr. Forster, a patron of mineralogy.

Artif.—Artificial magnesia-chrysolite has been made by Ebelmen, by fusing together in a porcelain furnace a mixture of silica and magnesia, with carbonate of potash, or boric acid.

TITANIFEROUS CHRYSOLITE. A massive, reddish-brown mineral from the talcose schist of Pfunders in the Tyrol, having some resemblance to boltonite, and G.=3·25. Contains, according to Damour (Ann. d. M., IV. viii. 90), 3·5 to 5·3 of titanic acid, with 6 p. c. of protoxyd of iron. For analyses see Nos. 1 and 2 on page 257.

The condition of the titanium has not been satisfactorily ascertained. There is a deficiency of silica which it may supply. But if it exists in the mineral as titanic iron, the rest is a magnesian chrysolite, like boltonite, with but little $\dot{\text{Fe}}$ replacing $\dot{\text{Mg}}$.

258. MONTICELLITE. *Brooke*, Ann. Phil., 1831. Batrachit *Breith.*, Char., 307, 1832.

Orthorhombic, and isomorphous with chrysolite. Occurring planes, *i*-ĭ, *i*-2̆, *I*, 1-ĭ, 2-2̆. In crystals. Also massive, with two cleavages inclined to one another 115°, and another diagonal to this angle.

H.=5—5·5. G.=3·03—3·25. Lustre vitreous, slightly resinous in the massive variety. Colorless, yellowish-gray, pale greenish-gray, and whitish. Streak uncolored. Transparent to translucent. Fracture more or less conchoidal.

Var.—(1) *Monticellite*, in colorless to yellowish-gray crystals, from Vesuvius; G.=3·119—

3·245. (2) *Batrachite*, cleavable massive, of a pale greenish-gray color, or whitish. G.=3·033, Breith.

Comp.—$(\frac{1}{2}\,\dot{C}a+\frac{1}{2}\,\dot{M}g)^2\,\dddot{S}i$=Silica 38·5, lime 35·9, magnesia 25·6=100. One-eighth of the $\dot{M}g$ is replaced by $\dot{F}e$. Analyses: 1, Rammelsberg (Pogg., cix. 569); 2, id. (Pogg., li. 446):

	$\dddot{S}i$	$\dot{F}e$	$\dot{M}g$	$\dot{C}a$	ign.
1. *Monticellite*	37·89	5·61	22·04	34·92	——=100·46 Ramm.
2. *Batrachite*	37·69	2·99	21·79	35·45	1·27=99·19 Ramm.

Pyr., etc.—B.B. rounded only on the edges. Soluble in dilute muriatic acid to a clear solution, which on heating gelatinizes.

Obs.—Monticellite occurs in crystals imbedded in granular limestone with mica and augite, on Mt. Somma. *Batrachite* is found in small masses containing black spinel, at Mt. Rinzoni in the Tyrol.

Monticellite was named after the Italian mineralogist, Monticelli; *Batrachite* from βάτραχος, *frog* in allusion to the color.

259. CHRYSOLITE. Smaragdus?, Beryllus?, pt. *Vet.* Topazos? pt. *Plin.* Not Chrysolithus [=Topaz] *Plin.*, xxxvii. 42. Observed Planes.

Cleavage: $i\text{-}\breve{i}$ rather distinct. Massive and compact, or granular; usually in imbedded grains.

H.=6—7. G.=3·33—3·5. Lustre vitreous. Color green—commonly olive-green, sometimes brownish, grayish-red, grayish-green. Streak usually uncolored, rarely yellowish. Transparent—translucent. Fracture conchoidal. Double refraction positive; obtuse bisectrix normal to $i\text{-}\bar{i}$

Comp., Var.—$(\dot{M}g, \dot{F}e)^2\dddot{S}i$, with traces at times of $\dot{M}n$, $\dot{C}a$, $\dot{N}i$. The amount of $\dot{F}e$ varies much. When there are 9 $\dot{F}e$ to 50 $\dot{M}g$ (anal. 5, 7), the ratio of $\dot{F}e$ to $\dot{M}g$ is 1 : 10; when 16 $\dot{F}e$

to 44 $\dot{M}g$ (anal. 22) nearly 1 : 5; when 22½ $\dot{F}e$ to 39 $\dot{M}g$ (anal. 26) nearly 1 : 3; when 28½ $\dot{F}e$ to 32½ $\dot{M}g$, as in *hyalosiderite*, the ratio is 1 : 2, and the special formula $(\frac{2}{3}\dot{M}g+\frac{1}{3}\dot{F}e)^2\ddot{S}i$, or $2\dot{M}g^2\ddot{S}i+\dot{F}e^2\ddot{S}i$. This species is ordinarily divided into

1. *Precious.* Of a pale yellowish-green color, and transparent, so as to be fit for jewelry; G.=3·441, 3·3514. Occasionally seen in masses as large as "a turkey's egg," but usually much smaller. It has long been brought from the Levant for jewelry, but the exact locality is not known. Well defined crystals of chrysolite an inch across are very uncommon. The proportion of iron to magnesia may be either small or large, as in the following.

2. *Common; Olivine* of Werner. Dark yellowish-green to olive- or bottle-glass-green; G.=3·334, fr. Etna. Commonly disseminated in basalt and lavas, in grains, and also at times in large masses having a rectangular outline, showing that they are crystals, although made up apparently of grains; these masses sometimes weighing 30 lbs. Also constituting rocks.

Glinkite is pale-green chrysolite from talcose schist; G.=3·39—3·43, Herm. *Hyalosiderite* is a very ferruginous kind (anal. 27); the specimen analyzed was partially decomposed, being iridescent and submetallic in lustre.

Analyses: 1, 2, Damour (Ann. d. M., V. viii. 90); 3, Genth (Ann. Ch. Pharm., lxvi. 20); 4, id. (Am. J. Sci., II. xxxiii. 199); 5, Manice (ib., xxxi. 359); 6, 7, Stromeyer (Gel. Anz. Gött., 1824, 208; Pogg., iv. 193); 8, Walmstedt (Ak. H. Stockh., 1824, ii. 359, and Schw. J., xliv. 25); 9, Hauan (Verh. G. Reichs., 1867, 71); 10, Kjerulf (J. pr. Ch., lxv. 187); 11, Reuter (ZS. G., xvi. 342); 12, Madelung (ib.); 13, Waltershausen (Vulk. Gest., 117); 14, Rammelsberg (Min. Ch., 438); 15, Walmstedt (l. c.); 16, Stromeyer (l. c.); 17, Kalle (Ramm. Min. [a] With some $\dot{N}i$.

Berzelius detected oxyd of tin in the olivine of the Pallas meteorite; Rummler a trace of arsenous acid. A. Erdmann found a trace of fluorine in that of Elfdalen, and of Tunaberg. Walchner obtained in anal. 26 0·330 grms. of $\dot{F}e$ (out of 1·040 grms. under analysis), from which he deduced 30·9 grms. of $\dot{F}e$, or 29·71 p. c.

Pyr., etc.—B.B. whitens, but is infusible; with the fluxes gives reactions for iron. Hyalosiderite and other varieties rich in iron fuse to a black magnetic globule. Some varieties give reactions for titanic acid and manganese. Decomposed by muriatic and sulphuric acids with separation of gelatinous silica. G. before ignition, 3·389; after, 3·378.

Obs.—A common constituent of some eruptive rocks; and also occurring in or among metamorphic rocks, with talcose schist, hypersthene rocks, and serpentine; or as a rock formation, also a constituent of many meteorites. The eruptive rocks, basalt and basaltic lava, consist of chrysolite (the variety *olivine*), along with labradorite or other feldspar, and augite. Though usually in grains, it is sometimes in rectangular masses several inches thick.

A chrysolite rock occurring at L. Lherz, consisting largely of chrysolite, has been called *Lherzolyte* (See p. 147, under SPINEL). The *dunyte* of F. v. Hochstetter (ZS. G. Ges., xvi. 341) is the same rock, according to Sandberger. The latter has a grayish-green color, and greasy and vitreous lustre, with G.=3·295, and occurs with serpentine rock in Dun Mtn., near Nelson in New Zealand. Another similar rock from Moravia, called *picryte*, consists half of chrysolite, along with feldspar, diallage, hornblende, and magnetite. Another from Norway (called *Olivinfels* in German, or olivine rock) has very nearly the composition of pure chrysolite (anal. 9); G.=3·24—3·32, Kjerulf (l. c.); granular in texture; of olive to bottle-green color; it contains some talc, tremolite, and bronzite.

Occurs in eruptive rocks at Vesuvius, Sicily, Hecla, Sandwich Islands, and most volcanic islands or regions; at Expailly in Auvergne; at Unkel, on the Rhine, crystals several inches long; at Kapfenstein in Lower Styria, in spheroidal masses; at Sasbach and Ihringen in Kaiserstuhl, Switz.; near Freiburg, Baden, in dolerite, a variety containing much iron (*hyalosiderite*); in Thetford and Norwich, Vermont, in boulders of coarsely cryst. basalt, the crystals or masses several inches through; in dolerite or basalt in Canada, near Montreal, at Rougemont and Mounts Royal and Montarville (anal. 26).

In talcose schist, found near Kyschtimsk, N. of Miask, and near Syssersk in the Ural, in greenish imbedded nodules (*glinkite*, anal. 24); id. at Webster, in Jackson Co., N. C. (G.=3·28), along with serpentine, pyrosclerite, and chromite; with chromite in Loudon Co., Va.; in Lancaster Co., Pa., at Wood's mine, with serpentine and chromite (Genth); near Media, Delaware Co., Pa., with hornblende, magnetite, and chromite. In hypersthene rock at Elfdalen.

Among the meteorites containing chrysolite, there are the Pallas from Siberia, others from Atacama, Steinbach, etc.

On cryst., Kokscharof, Bull. Ak. St. Pet., ix. 235. Gives 1-$\breve{2}$ ∧ 1-$\breve{2}$, ov. O,=71° 30′, whence O ∧ 1-$\breve{2}$=125° 45′, i-$\breve{2}$ ∧ i-$\breve{2}$, ov. i-$\breve{i}$,=49° 55′, whence ov. i-$\bar{i}$=130° 5′.

Most of the crystals are fragile, and therefore unfit for use as gems.

Named from χρυσός, gold, and λίθος. The hyalosiderite, from ὕαλος, glass, and σίδηρος, iron.

The *Chrysolithus* of Pliny was probably our topaz; and his *topas* our *chrysolite*. But Pliny's statement that "topazos" is the largest of all the precious stones, and that a statue 4 cubits high was made of it, shows that he confounded together different stones, since solid chrysolite crystals are never as large as some topaz crystals, and two inches is an extraordinary magnitude. The hardness mentioned, that it yields to the action of the file and wears with use, is right, and seems to prove that true chrysolite was included under the name of *topazion*. It came from an island in the Red Sea, and was very highly valued. It is stated by Diodorus Siculus to have resembled glass, but to have had a remarkable golden appearance, especially conspicuous at night (King).

Alt.—Alteration of chrysolite often takes place through the oxydation of the iron; the mineral becomes brownish or reddish-brown and iridescent It also splits into thin laminæ as the change goes on, sometimes so as to resemble a mica. A basalt thus changed was once pointed out to the author as a mica slate, although no further change had taken place than that here mentioned *Chusite*, *Limbilite*, and *Sideroclepte* of Saussure (J. de Phys., 341, 1794), all from Limburg in Brisgau, are chrysolite more or less altered. The process may end in leaving the cavity of the crystal filled with limonite or red oxyd of iron.

Under the action of carbonated waters, the iron is often carried off instead of being peroxydized, and also some of the magnesia is removed at the same time; and thus may come *serpentine*, *picrosmine*, which often retain the crystalline form of chrysolite. A further change may produce *steatite* and other magnesian species.

For analyses of altered chrysolite see Walmstedt, in Ak. H Stockh., 1824, and Ramm. Min. Ch., 441; Rhodius in Ann. Ch. Pharm., lxiii 116, and Ramm. Min. Ch., 441; Lewinstein in Jahresb., 1860, 757; A. Madelung, Jahrb. G. Reichs., xiv. 1, Jahrb. Min., 1864, 628; W. Jung, B. H. Ztg., xxii. 289.

260. FAYALITE. *C. G. Gmelin*, Pogg., li. 1839. Eisenperidot, Eisenglas, *Germ.* Iron Chrysolite. Anhydrous Silicate of Iron.

Massive, crystalline. Cleavage in two directions at right angles to one another

H.=6·5. G.=4—4·14; 4·138, Fayal; 4·006, Ireland, Delesse. Lustre metalloid, somewhat resinous in the fracture. Color black, greenish, or brownish-black; sometimes iridescent. Opaque. Fracture imperfectly conchoidal. Attractable by the magnet.

Comp.—$\dot{\mathrm{Fe}}^2\ddot{\mathrm{Si}}$=Silica 29·5, protoxyd of iron 70·5=100. Analyses: 1, Gmelin (Pogg., ii 160); 2, Fellenberg (ib.); 3, Rammelsberg (Min. Ch., 435); 4, Thomson (Min., i. 461); 5, Delesse (Bull. G. Fr., II. x. 568):

	$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Cu}}$
1. Fayal	30·24	3·54	58·27	3 54	——	——	0·86, Fe S 2·33=98·78 Gmelin.
2. "	29·15	4·06	60·95	0·69	2·38	0·72	0·31, $\dot{\mathrm{Pb}}$ 1·55=99·81 Fell.
3. "	28·27	3·45	63·80		tr.	0·45	1·29, Fe S 3·35=100·61 Ramm.
4. Slavcarrach	29·60	——	68·73	1·78	——	——	——=100·11 Thomson.
5. "	29·50	tr.	63·54	5·07	0·30	——	——=98·41 Delesse.

Pyr., etc.—Fuses readily to a black magnetic globule. Gelatinizes with acids.

Obs.—From the Mourne Mts., Ireland, at Slavcarrach, near Bryansford, in pegmatite; forms nodules in volcanic rocks at Fayal, of the Azores. Obsidian or volcanic glass often approaches fayalite in composition.

Artif.—Iron-chrysolite sometimes occurs in crystals as a furnace slag, as noticed by Hausmann in 1812, and later by Mitscherlich and others. The *vulkanisches Eisenglas* of Klaproth (Beitr., v. 222), which afforded the above composition, was a slag according to G. Rose. It is a common product of the puddling furnace.

261. IRON-MANGANESE CHRYSOLITE. (*A. Erdmann*, Ak. H. Stockh., 1849; var. olivine, his Min., 278, 1853.) Near fayalite, but contains, besides protoxyd of iron, some protoxyd of manganese and lime, with also a little magnesia, approaching thus hyalosiderite.

One of three agreeing analyses afforded Erdmann (l. c.):

$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$
29·16	1·56	55·87	8·47	3·28	2·29=100·58.

It gives the formula, 6 $\dot{\mathrm{Fe}}^2\ddot{\mathrm{Si}}$+1 $\dot{\mathrm{Mn}}^2\ddot{\mathrm{Si}}$+$(\dot{\mathrm{Mg}}, \dot{\mathrm{Ca}})^2\ddot{\mathrm{Si}}$, Rammelsberg. It occurs in a gneissoid rock called *Eulysyte*, consisting in part of augite and garnet, at Tunaberg in Sweden.

A *furnace-product*, which is a *lime-iron-manganese* chrysolite, has been observed in clove-brown crystals at an iron-furnace in Easton, Pa. An analysis afforded Dr. C. T. Jackson (Am. J. Sci., II. xix. 358), $\ddot{\mathrm{Si}}$ 33·70, $\dot{\mathrm{Ca}}$ 31·80, $\ddot{\bar{\mathrm{Fe}}}$ 18·00, $\dot{\mathrm{Mn}}$, $\ddot{\bar{\mathrm{Mn}}}$ 14·90, $\ddot{\bar{\mathrm{Al}}}$ 3·50=101·90. Taking the iron and manganese as protoxyd, as so regarded by Dr. Jackson, the formula is $(\dot{\mathrm{Ca}}, \dot{\mathrm{Fe}}, \dot{\mathrm{Mn}})^2\ddot{\mathrm{Si}}$.

262. TEPHROITE. Tephroit *Breith.*, Char., 278, 1823, 212, 329, 1832.

Orthorhombic. Crystalline-massive. Cleavage in three directions rectangular in intersection, one perfect, a second a little less so, the third imperfect, or rather indistinct.

H.=5·5—6. G.=4—4·12. Lustre somewhat adamantine. Color grayish flesh-red, reddish-brown, and rose-red, to ash-gray, smoky-gray. Streak pale gray. Darkens, on exposure, to brown and black. Translucent—subtranslucent. Optic-axial plane parallel to plane of perfect cleavage; divergence for red rays, 159° 1′; in oil, 84° 19′.

Var.—1. *Normal* (anal. 1–5). 2. *Magnesian*, or *picrotephroite* (anal. 6–9). G. of No. 6, a brown kind, 3·97; of No. 7, a red, 3·87. Resembles much a cleavable feldspar.

Comp.—$\dot{\mathrm{Mn}}^2\ddot{\mathrm{Si}}$=Silica 29·8, protoxyd of manganese 70·2=100; or $(\dot{\mathrm{Mn}}, \dot{\mathrm{Mg}})^2\ddot{\mathrm{Si}}$. Analyses: 1, Thomson (Min., 1, 514); 2, Rammelsberg (Pogg., lxii. 145); 3, H. Deville (Descl. Min., i. 38); 4, G J Brush (Am. J. Sci., II. xxxvii. 66); 5, Igelström (Œfv. Ak. Stockh., 1865, 228); 6, 7, P. Collier and A. Hague (see No. 4); 8, Damour (Ann. d. M., VI. ii. 339); 9, Igelström (l. c.):

	$\ddot{\mathrm{Si}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Zn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	ign.
1. Franklin	29·64	0·82	66·60	——	——	——	2·70=99·76 Thomson.
2. Sparta	28·66	2·92	68·88	——	——	——	——=100 46 Rammelsberg.

	$\ddot{\mathrm{S}}$i	$\dot{\mathrm{F}}$e	$\dot{\mathrm{M}}$n	$\dot{\mathrm{Z}}$n	$\dot{\mathrm{M}}$g	$\dot{\mathrm{C}}$a	ign.
3. Sparta	28·37	2·16	59·31	7·58	2·16	0·39	——=99·97 Deville.
4. "	30·19	1·09	65·59	0·27	1·38	1·04	0·37=99·93 Brush.
5. Paisberg, *red*	30·82	——	56·83	——	2·79	5·37	2·20=98·01 Igelström.
6. Sparta, *brown*	30·55	1·52	52·32	5·93	7·73	1·60	0·28=99·93 Collier.
7 " *red*	31·73	0·23	47·62	4·77	14·03	0·54	0·35=99·27 Hague.
8 Franklin	29·95	1·96	36·43	11·61	18·60	——	1·71=100·26 Damour.
9. Paisberg, *brown*	31·36	4·15	44·07	——	17·71	*tr.*	0·87, $\dot{\mathrm{P}}$b, $\bar{\mathrm{A}}$s, $\ddot{\mathrm{C}}$ *tr.*=98·16 Igelst

Analysis No. 4 was of a specimen received from Breithaupt, as the original tephroite; Nos. 6, 7, from specimens obtained by Brush at Stirling Hill, in Sparta. The zinc in anal. 3–7 was undoubtedly from mixed zincite, this mineral occurring as a thin scale or lamina in the direction of the cleavage, and hence often covering cleavage surfaces (Brush). Anal. 7 corresponds to ($\frac{2}{3}$ $\dot{\mathrm{M}}$n + $\frac{1}{3}$ $\dot{\mathrm{M}}$g) $\ddot{\mathrm{S}}$i; anal. 8, to ($\frac{1}{2}$ $\dot{\mathrm{M}}$n + $\frac{1}{2}$ $\dot{\mathrm{M}}$g) $\ddot{\mathrm{S}}$i; and in anal. 9, $\dot{\mathrm{M}}$n : $\dot{\mathrm{M}}$g=5 : 4.

Pyr., etc.—B.B. fuses at 3·5 to a black scoria. Gelatinizes perfectly in muriatic acid without evolving chlorine. With the fluxes gives reactions for manganese and iron. The magnesian variety fuses at 4 (No. 6) to 6 (No. 7).

Obs.—Found at Stirling Hill in Sparta, N. J., with zincite, willemite, and franklinite, in cleavable masses; also at Paisberg, in Wermland, Sweden, along with rhodonite and other manganesian minerals; at Sjögrufvan, with hausmannite.

The name *tephroite* is from τεφρός, *ash-colored*. Breithaupt's original specimen was from the collection of H. Heyer at Dresden.

262A. HYDROTEPHROITE. L. J. Igelström has described (Œfv. Ak. Stockh., 1865, 605) a hydrous tephroite from Paisberg, which has a pale reddish color, a colorless streak, and H.=4; gelatinizes with acids and yields water. He obtained in an analysis $\ddot{\mathrm{S}}$i 28·46, $\bar{\mathrm{M}}$n 0·49, $\dot{\mathrm{M}}$n 53·44, $\dot{\mathrm{M}}$g 11·89, $\dot{\mathrm{C}}$a, $\dot{\mathrm{F}}$e *tr.*, $\dot{\mathrm{H}}$ 5·85=100·13, and corresponding to ($\dot{\mathrm{M}}$n, $\dot{\mathrm{M}}$g)^2 $\ddot{\mathrm{S}}$i+$\frac{2}{3}$ $\dot{\mathrm{H}}$. It may be an altered tephroite.

A black silicate of manganese from Klapperud, Dalecarlia, having a submetallic lustre and yellowish-brown streak, afforded Klaproth (Beitr., iv. 137) $\ddot{\mathrm{S}}$i 25·0, $\dot{\mathrm{M}}$n 55·8, $\dot{\mathrm{H}}$ 13·0=93·8=$\dot{\mathrm{M}}$n^3 $\ddot{\mathrm{S}}$i + 2 $\dot{\mathrm{H}}$, agreeing with the tephroite, excepting the water. Klaproth obtained 60 p. c. of $\dot{\mathrm{M}}$n, $\bar{\mathrm{M}}$n, whence the above is deduced by Berzelius.

263. KNEBELITE. Knebelit *Döbereiner*, Schw. J., xxi. 49, 1818.

Crystalline massive.

H.=6·5. G.=3·714, Döbereiner; 4·122, Erdmann. Lustre glistening. Color gray, spotted dirty-white, red, brown, and green; also grayish-black to black. Opaque to translucent. Brittle; fracture subconchoidal.

Comp.—($\frac{1}{2}$ $\dot{\mathrm{F}}$e + $\frac{1}{2}$ $\dot{\mathrm{M}}$n)^2 $\ddot{\mathrm{S}}$i=Silica 29·6, protoxyd of iron 35·5, protoxyd of manganese 34·9=100. Analyses: 1, Döbereiner (Schw. J., xxi. 49); 2, A. Erdmann (Dannemora Jernmalmsfält, p. 54):

	$\ddot{\mathrm{S}}$i	$\dot{\mathrm{F}}$e	$\dot{\mathrm{M}}$n	$\dot{\mathrm{M}}$g
1. Ilmenau	32·5	32·	35·	——=99·5 Döbereiner.
2. Dannemora	30·26	34·30	34·47	0·25, $\bar{\mathrm{A}}$l 1·59=100·87 Erdmann.

Pyr., etc.—According to Döbereiner, unaltered B.B., but Erdmann's mineral fused easily to a lustreless magnetic bead, and gave with the fluxes reactions for iron and manganese. Decomposed readily by muriatic acid with separation of gelatinous silica.

Obs.—The mineral analyzed by Döbereiner was from an unknown locality, but G. Suckow (Kenng. Ueb. Min., 1855, 93) states, on the authority of Knebel, that it was found in granite near Ilmenau. The Dannemora mineral is grayish-black to black in large masses, light gray on the thin edges, and is stated to cleave parallel to a prism of about 115°.

Named after Major von Knebel.

264. LEUCOPHANITE. Leukophan *Esmark*, Ak. H. Stockh., 1840, 191; Tamnau, Pogg., xlviii. 504. Leucophane. Leucofanite.

Orthorhombic. $I \wedge I$ about 91° (90° to 93°, Greg; 91° 3′, B. & M.); $O \wedge 1\text{-}\bar{i}$, calc.,=145° 52′. Approximate angles, $O \wedge 2$=117°–118° 30′, $O \wedge 2\text{-}\bar{i}$=126° 25′. A plane $m\text{-}n$ on O=140° 30′, on one plane I=126°

30′, on other I=101° 30′, Greg. Crystals tabular and nearly rectangular. Cleavage: basal perfect; imperfect in another direction, inclined 126° 25′ to the base; and perhaps in a third, at right angles to O. Usually massive.

H.=3·5—4. G.=2·974. Lustre vitreous on a cleavage surface. Color pale dirty green to wine-yellow; thin fragments transparent and colorless. Powder white, and strongly phosphorescent, whether heated or struck. Electric when heated. Optically biaxial; bisectrix normal to the base, plane of axes the macrodiagonal; Descl.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\dddot{S}i$=3 : 3 : 10; ($\frac{1}{2}$ ($\dot{C}a$, $\dot{N}a$)+$\frac{1}{2}$ $\ddot{\bar{B}}e$)^3 $\dddot{S}i$+$\frac{3}{2}$ $\dddot{S}i$; or else with half the excess of silica basic. Part of the oxygen replaced by fluorine. Analyses: 1, Erdmann (Ak. H. Stockh., 1840); 2, Rammelsberg (Pogg., xcviii. 257):

	$\dddot{S}i$	$\ddot{\bar{A}}l$	$\ddot{\bar{B}}e$	$\ddot{\bar{M}}n$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	F
1.	47·82	—	11·51	1·01	25·00	10·20	0·31	6·17=102·02 Erdmann.
2.	47·03	1·03	10·70	*tr.*	23·37	11·20	0·30	6·57=100·43 Ramm.

O. ratio, leaving out of view the fluorine, for $\dot{C}a$, $\ddot{\bar{B}}e$, $\dddot{S}i$, from anal. 1, 3 : 3 : 10·6; from 2, 3 : 2·8 : 10·0.

Pyr., etc.—In the closed tube whitens and phosphoresces with a purple light. B.B. in the forceps phosphoresces and fuses with intumescence at 3 to a clear colorless glass, which becomes opaque-white on flaming; imparts an intense yellow color to the flame. Fused with salt of phosphorus in the open tube gives the reaction for fluorine.

Obs.—Leucophane occurs in syenite with albite, elæolite, and yttrotantalite, on the small rocky islet Lamöe, near the mouth of the Langesund fiord in Norway, where it was found by Esmark. It resembles somewhat a light-green variety of apatite.

Named from λευκός, *white*, and φαίνω, *I appear*.

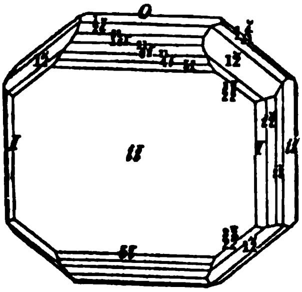
On cryst., see Greg, Phil. Mag., IV. ix. 510; Dana, Am. J. Sci., II. xxi. 205; Descl. Min., i. 144.

265. WÖHLERITE. Wöhlerit *Scheerer*, Pogg., lix. 327, 1843.

Orthorhombic. $I \wedge I$=90° nearly, $O \wedge 1\text{-}\bar{i}$=144° 37′; $a : b : c$=0·7162 : 1 : 1±

$O \wedge \frac{1}{2}\text{-}\bar{i}$=160° 27′
$O \wedge \frac{3}{2}\text{-}\bar{i}$=133 11
$O \wedge \frac{11}{4}\text{-}\bar{i}$=117 07
$O \wedge 1\text{-}\breve{2}$=141 30
$i\text{-}\bar{i} \wedge i\text{-}\breve{2}$=116 34
$i\text{-}\bar{i} \wedge I$=135 ±
$i\text{-}\breve{2} \wedge i\text{-}\breve{2}$, ov. $i\text{-}\breve{i}$,=126 52
$i\text{-}\breve{3} \wedge i\text{-}\breve{3}$, ov. $i\text{-}\breve{i}$,=143 8
$\frac{1}{2}\text{-}\bar{i} \wedge \frac{1}{2}\text{-}\bar{i}$, ov. O,=140 54

288



In tabular crystals and prisms. Cleavage: $i\text{-}\bar{i}$ distinct and easy. Also granular.

H.=5·5. G.=3·41. Lustre vitreous, inclining to resinous. Color light-yellow, wine-, honey-, resin-yellow, brownish, grayish. Streak-powder yellowish-white. Transparent—subtranslucent. Fracture more or less conchoidal—splintery.

Comp.—O. ratio for ($\dot{C}a$, $\dot{M}g$, $\dot{N}a$), $\ddot{Z}r$, $\dddot{S}i$, ($\dot{F}e$, $\dot{M}n$), $\ddot{\ddot{C}}b$=9·78 : 5·08 : 15·89 : 0·77 : 8·57; from Scheerer's analysis (with which Hermann's agrees nearly), whence Scheerer deduces a formula making it a columbate of zirconia+5 parts of a silicate of soda and lime. It corresponds well to the formula ($\frac{3}{4}$($\dot{C}a$, $\dot{M}g$, $\dot{N}a$)^3+$\frac{1}{4}$$\ddot{Z}r$) $\dddot{S}i$ [+ $\frac{1}{10}$ ($\dot{F}e$, $\dot{M}n$) $\ddot{\ddot{C}}b$], the last member *columbite*.

Analyses: 1, Scheerer (l. c.); 2, Hermann (Bull. Soc. Nat. Moscow, xxxviii. 467):

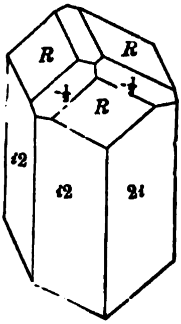
	$\ddot{\text{Si}}$	$\ddot{\text{Cb}}$	$\ddot{\text{Zr}}$	$\overline{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{H}}$
1. Brevig	30·62	14·47	15·17	2·12	1·55	26·19	7·78	0·24, $\dot{\text{Mg}}$ 0·4=98·14 Scheerer.
2. "	29·16	11·58	22·72	$\dot{\text{Fe}}$ 1·28	1·52	24·98	7·63	1·33=99·61 Herm.

Pyr., etc.—B.B. in a strong heat fuses to a yellowish glass. With the fluxes gives the reaction of manganese, iron, and silica. Dissolves easily when heated in strong muriatic acid, with a separation of the silica and columbic acid.

Obs.—Occurs with elæolite in zircon-syenite, on several islands of the Langesund fiord, near Brevig in Norway. Some crystals are nearly an inch long. On cryst., Descl., in Ann. Ch. Phys., III. xl., and Ann. d M., V. xvi. 229; Dauber, Pogg., xcii. 242. Descloizeaux, in his later paper, makes *i*-ī and *i*-ĭ the vertical faces of the prism *I*, with *I*∧*I*=90° 16′, and he describes the crystals as hemihedral in many planes.

266. WILLEMITE. Siliceous Oxyd of Zinc, Silicate of Zinc (fr. N. Jersey), *Vanuxem & Keating*, J. Ac. Philad., iv. 8, 1824. Willemite (fr. Moresnet) *Levy*, Jahrb. Min. 1830, 71; Ann. d. M., IV. iv. 513, 1843. Williamsite, Wilhelmite, Villemite, *alt. orthogr.* Anhydrous Silicate of Zinc. Hebetin (fr. Moresnet) *Breith.*, Char., 130, 1832. Troostite (fr. N. J.) *Shep.*, Min., 1st part, 154, 1832.

239



Rhombohedral. $R \wedge R$=116° 1′, $O \wedge R$=142° 17′; a=0·67378. Observed planes: in crystals fr. N. Jersey, *i*-2, *R*, $-\frac{1}{2}$, 1^s; fr. Moresnet *O*, *I*, $\frac{3}{4}$. $R \wedge \frac{1}{2}$=148° 1′. $R \wedge 1^s$=150° 5′, $1^s \wedge i\text{-}2$=151° 55′, $R \wedge i\text{-}2$=121° 59′; $\frac{3}{4} \wedge \frac{3}{4}$=128° 30′; Levy. Cleavage: *i*-2 easy in N. Jersey crystals; *O* easy in those of Moresnet. Also massive and in disseminated grains. Sometimes fibrous.

H.=5·5. G=3·89—4·18. Lustre vitreo-resinous, rather weak. Color whitish or greenish-yellow, when purest; apple-green, flesh-red, grayish-white, yellowish-brown; often dark-brown when impure. Streak uncolored. Transparent to opaque. Brittle. Fracture conchoidal. Double refraction strong; axis positive.

Var.—The crystals of Moresnet and New Jersey differ in occurring forms as above described. The latter are often quite large, and pass under the name of *troostite;* they are commonly impure from the presence of manganese and iron. G. of crystals from New Jersey, 3·89—4, Vanuxem and Keating; 4·02, Herm.; 4·154, Delesse; from Moresnet, 3·935, Thomson; 4·16—4·18, Levy; from Stolberg, 4·18, Monheim.

Comp.—$\dot{\text{Zn}}^2 \ddot{\text{Si}}$=Silica 27·1, oxyd of zinc 72·9=100. Analyses: 1, 2, Vanuxem and Keating (l. c.); 3, Hermann (J. pr. Ch., xlvii. 11); 4, Delesse (Ann. d. M., IV. x. 213); 5, H. Wurtz (Rep. Am. Assoc., iv. 147); 6, Thomson (Min., i. 545); 7, Levy (Ann. d. M., IV. iv. 513); 8, Monheim (Verh. nat. Ver. Bonn., 1848, 157); 9, Damour (Descl. Min., 554):

9. Greenland	27·86	——	——	0·37		71·51	——	——=99·74 Damour.

[a] With a trace of zinc and iron.

First analyzed and described by Vanuxem and Keating.

Pyr., etc.—B.B. in the forceps glows and fuses with difficulty to a white enamel; the varieties from New Jersey fuse from 3·5 to 4. The powdered mineral on charcoal in R.F. gives a coating yellow while hot and white on cooling, which, moistened with solution of cobalt, and treated in O.F., is colored bright green. With soda the coating is more readily obtained. Decomposed by muriatic acid with separation of gelatinous silica.

Obs.—From Vieille-Montagne near Moresnet, between Liège and Aix-la-Chapelle, in crystals and massive, the crystals but a few millimeters in length; also at Stolberg near Aix-la-Chapelle; at Raibel in Carinthia; at Kucsaina in Servia and in Greenland in compact quartz. In New Jersey at both Franklin and Stirling in such quantity as to constitute an important ore of zinc. It occurs intimately mixed with zincite and franklinite, and is found massive of a great variety of colors, from pale honey-yellow and light green to dark ash-gray and flesh-red; sometimes in crystals (*troostite*) six inches long and an inch or more thick, imbedded in franklinite and also in calcite.

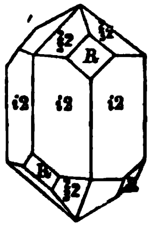
Named by Levy after William I., King of the Netherlands.

267. PHENACITE. Phenakit *N. v. Nordenskiöld*, Ak. H. Stockh., 160, 1823, Pogg., xxxi. 57

Rhombohedral; often hemihedral. $R \wedge R = 116° 36'$, $O \wedge R = 142° 38'$, Kokscharof; $a = 0{\cdot}661065$. Observed planes: rhombohedrons, R, -2, -1, $-\frac{1}{2}$; scalenohedrons, 1^3, 1^5, -2^3, $\frac{4}{5}^3$ (bevelling terminal edge of R); pyramids, $\frac{4}{3}$-2, $\frac{2}{3}$-2; prisms, I, i-2, i-$\frac{3}{2}$; hemihedral, $\frac{r}{l}\ \frac{4}{3}\text{-}\frac{4}{3}$, $\frac{l}{r}\ \frac{4}{3}\text{-}\frac{4}{3}$, $\frac{r}{l}\ 3\text{-}\frac{3}{2}$, Koksch. Min. Russl., ii. 308, iii. 81.

$R \wedge I = 127° 21'$ $\qquad$ $R \wedge -2 = 160° 35'$
$R \wedge i\text{-}2 = 121\ 42$ $\qquad$ $R \wedge -\frac{1}{2} = 148\ 18$
$\frac{4}{3}\text{-}2 \wedge \frac{4}{3}\text{-}2 = 156\ 44$ $\qquad$ $\frac{1}{2} \wedge \frac{1}{2} = 144\ 4$
$\frac{4}{3}\text{-}2 \wedge R = 159\ 56$ $\qquad$ $2 \wedge 2 = 87\ 12$

240



Crystals sometimes oblong, as in fig. 240; but often the prism nearly or quite wanting, and the form that of a low obtuse rhombohedron, with replaced edges and lateral angles. Cleavage: i-2 distinct, R imperfectly so. Twins: composition-face i-2.

H.=7·5—8. G.=2·96—3. Lustre vitreous. Colorless; also, bright wine-yellow, inclining to red; brown. Transparent—subtranslucent. Fracture like that of quartz. Double refraction positive.

Comp.—$\dot{B}e^3\dddot{S}i$=Silica 54·2, glucina 45·8=100. Analyses: 1, Hartwall (Pogg., xxxi. 57), 2, Bischof (Pogg., xxxiv. 525):

1. Ural	$\dddot{S}i$ 55·14	$\dot{B}e$ 44·47	$\ddot{\bar{A}}l$ and $\dot{M}g$ *tr.*=99·61	Hartwall.
2. Framont	54·40	45·57	$\dot{C}a$ and $\dot{M}g$ 0·09=100·06	Bischof.

Pyr., etc.—Alone remains unaltered; with borax fuses with extreme slowness, unless pulverized, to a transparent glass. With soda affords a white enamel; with more, intumesces and becomes infusible. Dull blue with cobalt solution.

Obs.—Occurs in mica schist at the emerald and chrysoberyl mine of Takovaja, 85 versts E. of Katherinenburg, where the crystals are sometimes nearly 4 inches across, and one found weighs 1¼ lbs.; also in small crystals on the east side of the Ilmen Mts., 5 versts N. of Miask, along with topaz and green feldspar; also in highly modified crystals with quartz, in limonite, near Framont in Alsace; at Mt. Mercado, near Durango, Mexico, in limonite and magnetite, the crystals numerous, but not fresh, being below the true hardness; and in a valley on the summit of La Cruz, on the side of the rancho of Tinaja, it forms, according to G. Weidner, a rock, containing hornblende and actinolite.

Named from φέναξ, *a deceiver*, in allusion to its having been mistaken for quartz.

268. MELIPHANITE. Melinophan *Scheerer*, J. pr. Ch., lv. 449, 1852. Meliphane *Dana*, Am J. Sci., II. xliv. 405, 1867.

Tetragonal or hexagonal. Massive, and consisting sometimes of plates or lamellæ, but not as a result of cleavage structure. Cleavage hexagonal (?), in traces.

H.=5. G.=3·0, Richter; 3·018, Rammelsberg. Lustre vitreous. Color sulphur, citron, or honey-yellow. Transparent to translucent. Brittle. Double refraction strong, uniaxial; axis negative; Descl.

Comp.—Formula perhaps as on p. 250. **Analyses:** 1, imperfect, by R. Richter (l. c.); 2, Rammelsberg (Pogg., xcviii. 297):

$\dddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Mn}}$	$\bar{\text{Fe}}$	$\bar{\text{Be}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\dot{\text{Na}}$	F	
44·8	12·4	1·4	1·1	2·2	31·5	0·2	2·6	2·8	$\ddot{\text{Cb}}$, $\ddot{\text{Zr}}$, $\bar{\text{Ce}}$, $\dot{\text{Y}}$ 0·3=98·8 Richter.
43·66	1·57			11·74	26·74	0·11	8·55	5·73,	$\dot{\text{K}}$ 1·40, $\dot{\text{H}}$ 0·30=99·80 Ramm.

Rammelsberg's analysis, if the fluorine is taken as replacing part of the oxygen in the bases and acid, gives for the oxygen (including the fluorine) ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\dddot{\text{Si}}$ 8·7 : 3 : 8·3. The exact nature of the compound is still doubtful. Rammelsberg deduces the same formula as that for leucophane, taking as the common oxygen ratio 4 : 3 : 9. But Descloizeaux's optical examinations make the two distinct species.

Pyr., etc.—B.B. in the forceps does not phosphoresce, fuses with intumescence to a white enamel; in other respects resembles leucophane.

Obs.—From the zircon-syenite of Norway, near Fredericksvärn, with elæolite, mica, fluorite, and magnetic iron. An imperfect crystal in the cabinet of R. P. Greg, Esq., gave him for the angle between two prismatic faces 133°; the edge between these two faces was replaced by a rough plane, apparently not equally inclined.

Named from *μέλι*, *honey*, and *φαίνω*, *I appear*, from the honey-yellow color. [Scheerer misswrote the word *melinophane*, which would come from *μέλινος*, *ashen*, or *μελίνη*, *millet*.] The dropping of the *i* of the genitive, as done above, has classical authority.

269. HELVITE. Ein Fossil w. Aehnlichk. m. d. Granat hat, aber nicht Granat zu seyn scheint, *Mohs*, Null Kab., i. 92, 1804. Helvin *Wern.*, 1816, Breith. in Hoffm. Min., iv. b. 112, 1817. Wern. Letztes Min. Syst., 2, 29, 1817; Tetrahedral Garnet *Mohs*, Char. Syst. Min., 71, 1820, Edinb. Tetraëdrischer Granat *id.*, Grundr., 412, 1824.

Isometric: tetrahedral. Figs. 31, 32. Cleavage: octahedral, in traces.

H.=6–6·5. G.=3·1–3·3; 3·216, Breithaupt. Lustre vitreous, inclining to resinous. Color honey-yellow, inclining to yellowish-brown, and siskin-green; streak uncolored. Subtranslucent. Fracture uneven.

Comp.—O. ratio for $\dot{\text{R}}$, $\dddot{\text{Si}}$=1 : 2; for $\dot{\text{Mn}}$+$\dot{\text{Fe}}$, $\bar{\text{Be}}$=1 : 1; formula $(\frac{1}{2}(\dot{\text{Mn}}, \dot{\text{Fe}})+\frac{1}{2}\bar{\text{Be}})^2\dddot{\text{Si}}+\frac{1}{2}\text{Mn}\,\text{S}$, Ramm.

Analyses: 1, 2, Gmelin (Pogg., iii. 53); 3, Rammelsberg's correction of Gmelin's anal. 1 (Min. Ch., 701); 4, Rammelsberg (ib.):

	$\dddot{\text{Si}}$	$\bar{\text{Be}}$	$\dot{\text{Mn}}$	$\dot{\text{Fe}}$	Mn	S	ign.

4. Norway	33·13	11·46	36·50	4·00	9·77	5·71	——=100·57 Ramm.

[a] With some alumina.

Pyr., etc.—Fuses at 3 in R.F. with intumescence to a yellowish-brown opaque bead, becoming darker in R.F. With the fluxes gives the manganese reaction. Decomposed by muriatic acid, with evolution of sulphuretted hydrogen, and separation of gelatinous silica.

Obs.—Occurs in gneiss at Schwarzenberg in Saxony, associated with garnet, quartz, fluorite, and calcite; at Breitenbrunn, Saxony; at Hortekulle near Modum, and also at Brevig, in Norway in zircon-syenite.

Named by Werner, in allusion to its yellow color, from *ἥλιος*, *the sun*.

270. DANALITE. *J. P. Cooke*, Am. J. Sci., II. xlii 73.

Isometric. In octahedrons, with planes of the dodecahedron; the dodecahedral faces striated parallel to the longer diagonal.

H.=5·5–6. G.=3·427. Lustre vitreo-resinous. Color flesh-red to gray. Streak similar, but lighter. Translucent. Fracture subconchoidal, uneven. Brittle.

Comp.—$(\frac{1}{2}\dot{R}+\frac{1}{2}\dot{Be})^2\ddot{Si}+\frac{1}{2}Zn\,S$; in which $\dot{R}=\dot{Fe}, \dot{Mn}, \dot{Zn}$. Analyses: J. P. Cooke (l. c.):

	$\ddot{Si}$	$\dot{Fe}$	$\dot{Mn}$	$\dot{Zn}$	$\dot{Be}$	S
1. Rockport	($\frac{2}{3}$) 31·73	27·40	6·28	17·51	13·83	5·48=102·28.
2. Gloucester	29·88	28·18	5·71	18·15	14·72[a]	4·82, $\dot{Ca}$ 0·83, $\dot{Mg}$ tr.=102·24.

[a] With alumina.

By subtracting from anal. 1 oxygen 2·74, equivalent to the sulphur, the sum is 99·49; and from anal. 2, 2·41 p. c. oxygen, the sum is 99·83.

Pyr., etc.—B.B. fuses readily on the edges to a black enamel. With soda on charcoal gives a slight coating of oxyd of zinc. Perfectly decomposed by muriatic acid, with evolution of sulphuretted hydrogen and separation of gelatinous silica.

Obs.—Occurs in the Rockport granite, Cape Ann, Mass., small grains being disseminated through this rock; also near Gloucester, Mass.; in both localities associated with a lithia mica, in the latter, with green feldspar and fluorite.

Named after J. D. Dana.

---

271. GARNET.

'Aνθραξ pt. [rest Ruby Spinel and Sapphire] *Theophr.* Carbunculus pt. [rest id] *Plin.*, xxxvii. 25; Carchedonius, Garamanticus [=Carthaginian or Garamantic Carbuncle], Alabandicus [cut at Alabanda], Anthracitis, *Plin.*, ib., 25–27. Granatus *Albertus Magnus*, 232, 1270. Carbunculus Carchedonius=*Germ.* Granat, C. Alabandicus and Troezenius=*Germ.* Almandin, *Agric.*, Foss., 272, Interpr., 463, 1546. Granat *Wall.*, Min., 120, 1747. Garnet Grenat *Fr.*

Isometric. Observed planes: *O* (very rare), *I*, 1; trapezohedral, 2-2, $\frac{3}{2}$-$\frac{3}{2}$; tetrahexahedral, *i*-2, *i*-$\frac{3}{2}$, *i*-$\frac{11}{10}$; trisoctahedral, $\frac{3}{2}$; hexoctahedral, 3-$\frac{3}{2}$, 4-$\frac{4}{3}$. Dodecahedron, fig. 3, and the trapezohedron 2-2, fig. 10, most common; also figs. 11, 13, 14, 21, 28; octahedral form very rare; figs. 241–243 distorted dodecahedrons; f. 244, distorted trapezohedron; f. 246, combination of the dodecahedron and trapezohedron, but distorted, and having only four planes of the former.

Cleavage: dodecahedral, sometimes quite distinct. Twins: composition-face octahedral. Also massive; granular, coarse, or fine, and sometimes friable; lamellar, lamellæ thick and bent. Also very compact, cryptocrystalline like saussurite.

H.=6·5–7·5. G.=3·15–4·3. Lustre vitreous—resinous. Color red, brown, yellow, white, apple-green, black; some red and green colors often bright. Streak white. Transparent—subtranslucent. Fracture subconchoidal, uneven. Brittle, and sometimes friable when granular massive; very tough when compact cryptocrystalline.

Comp., Var.—Garnet is a unisilicate, of sesquioxyd and protoxyd bases, having the general formula $(\frac{1}{2}\dot{R}^3+\frac{1}{2}\ddot{\ddot{R}})^2\ddot{Si}^3$, or $(\dot{R}^3)^2\ddot{Si}^6+\ddot{\ddot{R}}^2\ddot{Si}^3$.

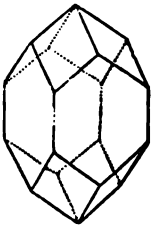
The name is from the Latin *granatus*, meaning *like a grain*, and directly from *pomegranate*, the seeds of which fruit are small, numerous, and red, in allusion to the aspect of the crystals.

There are three prominent groups, based on the nature of the predominating sesquioxyd.

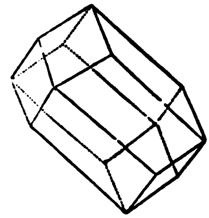
I. ALUMINAGARNET, in which the sesquioxyd is mainly *alumina* ($\ddot{\ddot{Al}}$).

II. IRONGARNET, in which it is largely *sesquioxyd of iron* ($\ddot{\ddot{Fe}}$), usually with some alumina.

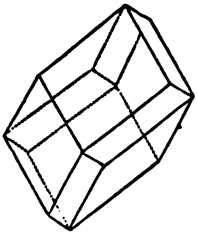
241



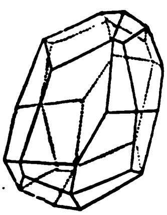
242



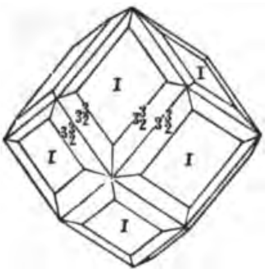
243



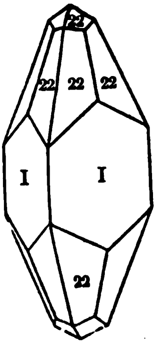
244



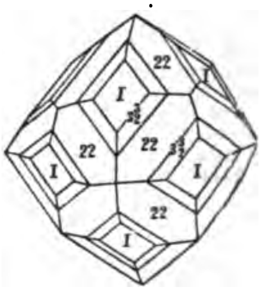
245



246



247



III. CHROMEGARNET, in which it is largely *sesquioxyd of chromium* ($\ddot{\bar{\mathrm{C}}}\mathrm{r}$).

The protoxyd bases present, either singly or two or more together, are *lime* ($\dot{\mathrm{C}}\mathrm{a}$), *magnesia* ($\dot{\mathrm{M}}\mathrm{g}$), *protoxyd of iron* ($\dot{\mathrm{F}}\mathrm{e}$), *protoxyd of manganese* ($\dot{\mathrm{M}}\mathrm{n}$), with rarely a few p. c. of *protoxyd* (?) *of chromium*, *protoxyd of nickel*, or *yttria*, or a trace of an *alkali*. Subdivisions of the above groups have been based on the predominance of one or another of these protoxyds; and on this ground there are the following varieties or subspecies:

A. GROSSULARITE, or *Lime-Aluminagarnet*.
B. PYROPE, or *Magnesia-Aluminagarnet*.
C. ALMANDITE. or *Iron-Aluminagarnet*.
D. SPESSARTITE, or *Manganese-Aluminagarnet*.
E. ANDRADITE, or *Lime-Irongarnet*, including 1, ordinary; 2, manganesian, or *Rothoffite*; 3, yttriferous, or *Yttergarnet*.
F. BREDBERGITE, or *Lime-Magnesia-Irongarnet*.
G. OUVAROVITE, or *Lime-Chromegarnet*.

Excepting the last, these subdivisions blend with one another more or less completely through varieties containing combinations of the protoxyd bases, and also of the sesquioxyd bases. The following are their characters. Most of the various names enumerated below under each division, making the synonymy, have stood for a time as names of supposed distinct species.

A. *Lime-Aluminagarnet*; GROSSULARITE. (Kanelstein [=Cinnamon Stone] fr. Ceylon [sp., placed near Zircon] *Wern.*, 1803, Ludwig's Wern., ii. 209, 1804; Essonite [sp.] *H.*, Tr. Pierres préc., 1817; Hessonite *Leonh.*, Handb., 433, 1821: Essonite [var. of Garnet] *Beud.*, 170, 1824. Romanzovit [fr. Kimito] *Nordenskiöld*, Schw. J., xxxi. 380. Grossularite [fr. Wilui R., Sib.] *Wern.*, 1808–9, Hofm. Min., i. 479, 1811; Granat *Pallas*, N. Nord. Beyt. St. Pet., 1793; Wiluit pt. [Viluit] *Severgin*. Grenat du chaux, ou Grossulaire, *Beud.*, 337, 1824.) A silicate mainly of alumina and lime; formula mostly $(\frac{1}{3}\dot{\mathrm{C}}\mathrm{a}^3+\frac{1}{3}\dddot{\mathrm{A}}\mathrm{l})^2\,\dddot{\mathrm{S}}\mathrm{i}^3$=Silica 40·1, alumina 22·7, lime 37·2=100. But some lime often replaced by protoxyd of iron, and thus graduating toward the Almandite group. Color (*a*) white; (*b*) pale green; (*c*) amber- and honey-yellow; (*d*) wine-yellow, brownish-yellow, cinnamon-brown; rarely (*e*) emerald-green from the presence of chromium. G.=3·4–3·75.

The original *grossularite* (*wiluite*) included the pale green from Siberia, and was so named from the botanical name for the gooseberry; G.=3·42–3·72. *Cinnamon-stone*, or *essonite*, included a cinnamon-colored variety from Ceylon, there called *hyacinth*; but under this name the yellow kinds are usually included. *Succinite* is an amber-colored kind from Ala, Piedmont. *Romanzovite* is a brown.

Pale green, yellowish, and yellow-brown garnets are no. invariably grossularite; some (including topazolite) belong to the group of Irongarnet, or Andradite (p. 268).

C. *Iron-Aluminagarnet*; ALMANDITE. (Precious or Oriental Garnet. Orientalischer Granat, Sirianischer (fr. Siriam in Pegu) Granat *Klapr.*, Beitr., ii. 22, 1798. Alamandin (Alabandicus Plin.) *Karst.*, Tab., 20. 69, 1800. Common Garnet pt. Fahlungranat *Berz.*, Lohthr.) A silicate mainly of alumina and protoxyd of iron; formula $(\frac{1}{3}\dot{\text{Fe}}^3+\frac{1}{3}\overset{\dots}{\text{Al}})^2\,\ddot{\text{Si}}^3$=Silica 36·1, alumina 20·6, protoxyd of iron 43·3=100; or $\dot{\text{Mn}}$ may replace some of the $\dot{\text{Fe}}$, and $\overset{\dots}{\text{Fe}}$ part of the $\overset{\dots}{\text{Al}}$. Color fine deep-red and transparent, and then called *precious garnet*; also brownish-red, and translucent or subtranslucent, *common garnet*; black, and then referred to var. *melanite*. Part of *common garnet* belongs to the *Andradite* group, or is irongarnet. The Alabandic carbuncles of Pliny were so called because cut and polished at Alabanda. Hence the name almandine, now in use. Pliny describes vessels of the capacity of a pint, formed from carbuncles, "non claros ac plerumque sordidos ac semper fulgoris horridi," devoid of lustre and beauty of color, which probably were large common garnets of the latter kind.

Pyrenees) *Wern.*, 1811–12, Hoffm. Min., ii. 373, 1815. Kalkgranat *Berz.*, Löthr. Granat v. Longban *Rothoff*, Afh., iii. 329, 1810; Rothoffite *Berz.*, N. Syst. Min., 218, 1819. Polyadelphite (fr. Franklin, N. J.) *Thom.*, Min. i, 154, 1836. Jelletite (fr. Mt. Rosa) *Apjohn*, J. G. Soc., Dublin, v. 119, 1853. Yttergranat (fr. Norway) *Bergemann*, Sitz. Ges. Bonn., July, 1854.) Colors various, including wine-, topaz-, and greenish-yellow (topazolite), apple-green; brownish-red, brownish-yellow; grayish-green, dark green; brown; grayish-black, black. G.=3·64—4.

Named *Andradite* by the author after the Portuguese mineralogist, d'Andrada, who described and named the first of the included subvarieties, Allochroite. The included kinds vary so widely in color and other respects that no one of the names in use will serve for the group.

Chemically there are the following subvarieties: 1. Simple *Lime Irongarnet*, in which the protoxyds are wholly or almost wholly lime. Includes: (*a*) *Topazolite*, having the color and transparency of topaz, and also sometimes green; although resembling essonite, Damour has shown that it belongs here. (*b*) *Colophonite*, a coarse granular kind, brownish-yellow to dark reddish-brown in color, resinous in lustre, and usually with iridescent hues; named after the resin *colophony* (*c*) *Melanite* (named from μελας, *black*), black, either dull or lustrous; but all black garnet is not here included. *Pyreneite* is grayish-black melanite; the original afforded Vauquelin 4 p. c. of water, and was iridescent, indicating incipient alteration. (*d*) Dark green garnet, not distinguishable from some allochroite, except by chemical trials. *Jelletite* is green garnet, light or dark, and yellowish-green, from the moraine of the Findel glacier near Zermatt, Mt. Rosa; named after Jellet, one of the describers of it.

Calderite, a mineral from Nepaul, India, is said to be nothing but massive garnet; but whether belonging to this group or not is not stated.

2. *Manganesian Lime-Irongarnet.* (*a*) *Rothoffite.* The original *allochroite* was a manganesian irongarnet of brown or reddish-brown color, and of fine-grained massive structure. The *Rothoffite*, from Longban, first analyzed by Rothoff, is similar, with the color yellowish-brown to liver-brown. Other common kinds of manganesian irongarnet are light and dark, dusky green and black, and often in crystals. Thomson's *Polyadelphite* was a massive brownish-yellow kind, from Franklin, N. J. (anal. 66, 67). The same locality affords another in dark green crystals, containing still more manganese.

(*b*) *Aplome* has its dodecahedral faces striated parallel to the shorter diagonal, whence Haüy inferred that the fundamental form was the cube; and as this form is simpler than the dodecahedron, he gave it a name derived from 'απλόος simple. Color of the original aplome (of unknown locality) dark brown; also found yellowish-green and brownish-green at Schwarzenberg in Saxony, and on the Lena in Siberia.

3. *Yttriferous Lime-Irongarnet*; *Yttergarnet.* Contains several p. c. of yttria (anal. 75); G.=3·88, Bergemann; B.B. infusible.

* Includes some Fe^2O^3.

Garnet usually contains no water, or only a trace of it, and thus differs from the related idocrase. The grossularite from Wilui afforded G. Magnus only 0·12 p. c.; the cinnamon-stone of Ala, 0·25—0·34; the almandine of Slatoust, none (Pogg., xcvi. 347).

In jewelry, the lighter clear garnets are often called hyacinth. The yellowish is the *Jacinta la bella;* a yellowish crimson, the *Guarnaccino;* and another very similar, *Vermeille*, or *Hyacinth-Garnet;* the red, with a violet tinge, *Rubino-di-rocca*, and also *Grenat Syrian* (from Syriam in Pegu), and probably the *Amethystizontes* of Pliny. The deep and clear red, like Burgundy wine in shade, is the true *precious garnet*, which is either pyrope or almandite. The ancient name ἄνθραξ, meaning *a burning coal*, alludes to the internal fire-like color and reflection, and was applied also to some ruby. The Latin name *carbunculus*, from *carbo, coal*, has the same signification.

Pyr., etc.—Most varieties fuse easily to a light-brown or black glass; F.=3 in almandite, spessartite, grossularite, and allochroite; 3·5 in pyrope; but ouvarovite, the chrome-garnet from Canada (No. 84 included), is almost infusible, F.=6. Allochroite and almandite fuse to a magnetic globule. Reactions with the fluxes vary with the bases. Almost all kinds react for iron; strong manganese reaction in spessartite, and less marked in other varieties; a chromium reaction in ouvarovite, and in most pyrope. Some varieties are partially decomposed by acids; all except ouvarovite are after ignition decomposed by muriatic acid, and generally with separation of gelatinous silica. Decomposed on fusion with alkaline carbonates.

A brownish-red Arendal garnet, having G.=4·058, was reduced by heating to G.=4·046, and by fusion to 3·596—3·204, Church; and a Ceylon essonite, having G.=3·666, had G.=3·681 after heating to incipient fusion, Church.

Obs.—Garnet crystals are very common in mica schist, gneiss, syenitic gneiss and hornblende and chlorite schist; they occur often, also, in granite, syenite, crystalline limestone, sometimes in serpentine, and occasionally in trap and volcanic tufa and lava.

Garnet is sometimes found in the massive form as a prominent constituent of a rock. A white variety (lime-aluminagarnet) occurs, forming, with a little serpentine, a whitish garnet rock at Orford in Canada, having G.=3·52—3·58. A similar *garnet-felsite* exists in Bayreuth in Bavaria. At St. François in Canada there is a yellowish-white and greenish-white garnet rock, consisting of the same garnet along with pyroxene, in the proportion, according to T. S Hunt, of 57·72 of the former to 40·71 of the latter, having G.=3·33, and affording on analysis, $\ddot{\text{Si}}$ 44·85, $\bar{\text{Al}}$ 10·76, $\bar{\text{Fe}}$ 3·20, $\dot{\text{Mg}}$ 5·24, $\dot{\text{Ca}}$ 34·38, ign. 1·10=99·58 (Rep. G. Can., 1863, 496). *Eclogyte* is a *garnet-euphotide*, consisting of a massive reddish garnet and grass-green smaragdite or omphacite. These garnet rocks are all very tough as well as heavy rocks.

Many foreign localities of garnet have been mentioned in the preceding pages, under the head of *composition* and *varieties*. The best *cinnamon-stone* comes from Ceylon, in gneiss; Malsjö in Wermland, in crystalline limestone; on the Mussa-Alp in Piedmont, with clinochlore and diopside, where the crystals present the planes *I*, 2-2, *i*-2, $\frac{3}{2}$, 3-$\frac{3}{2}$, *O*, 1; at Mittaghorn, in Switzerland, with the same minerals, reddish-brown in color, and having sometimes the planes *i*-2 and $\frac{3}{2}$ with *I* and 2-2; pale isabella-yellow at Auerbach, with the planes 2-2, *I*, 3-$\frac{3}{2}$, *i*-2, *i*-$\frac{3}{2}$; a brownish variety (*romanzovite*) at Kimito in Finland. A honey-yellow garnet in *octahedrons* occurs in Elba. Grossularite of pale greenish color, comes from the banks of the Wilui in Siberia, in serpentine with idocrase, and from Cziklowa, in the Bannat; in white or colorless crystals in Tellemark, in Norway, and the Schischimskaja Gora, in the Ural; also whitish in a resinopal pseudomorph after coral in Van Diemen's Land. Emerald-green crystals are found at Dobschau in Hungary. *Almandite* or precious garnet comes in fine crystals from Ceylon, Pegu, Brazil, and Greenland. Common garnet is found in dodecahedrons 3 to 4 inches through at Fahlun in Sweden, Arendal and Kongsberg in Norway, and the Zillerthal. *Allochroite*, an apple-green and yellowish variety, of different shades, occurs at Zermatt in Valais, in geodes of crystals in chlorite schist; brilliant black crystals (*melanite*) and also brown, at Vesuvius on Somma; and in a volcanic tufa at Frascati near Rome; peak Espada and that of Ereslids near Barèges in the Hautes-Pyrenees (*Pyreneite*). Aplome occurs in yellowish and brownish-green crystals at Schwarzenberg in Saxony, and on the borders of the Lena in Siberia. *Spessartite* at Spessart near Aschaffenburg in Bavaria; in the white feldspar of the granite of Elba, at St. Marcel, Piedmont, in pegmatite at Vilate near Chanteloube, Haute-Vienne; at Broddbo, near Fahlun, in Sweden; in a porphyritic trap, near Ilefeld in the Harz. Pyrope occurs in trap, tufa, and in the sands of the region, near Meronitz, Trziblitz, and Podsedlitz, in Bohemia, where alone the variety used as a gem is obtained; also at Zöblitz in Saxony, and the valley of Krems in Bohemia, in a serpentine rock. *Ouvarovite* is found at Saranovskaja near Bissersk, in the vicinity of Kyschtimsk, Urals, lining cavities or fissures in chromic iron; at Haule, in Rupshu, on chromite.

Near Cauterets, the Hautes-Pyrénées, large crystals of brown garnet have a nucleus, easily separable, of dull green crystallized idocrase; the containing rock is a compact gray limestone.

In N. America. in *Maine*, beautiful yellow crystals or cinnamon-stone (with idocrase) at Parsonsfield, Phippsburg, and Rumford; manganesian garnet at Phippsburg, as well as the finest yellow garnet in Maine; in mica slate near the bridge at Windham, with staurotide; in granite veins at Streaked Mountain, along with beryl; in large reddish-brown crystals at Buckfield, on the estates of Mr. Waterman and Mr. Lowe; handsome red garnets at Brunswick. In *N. Hamp.*, at Hanover, small clear crystals in syenitic gneiss; blood-red dodecahedrons at Franconia, in geodes in massive garnet, with calcite and magnetic iron; at Haverhill, in chlorite, some 1½ in.; at Warren, beautiful cinnamon garnets with green pyroxene; at Unity, on the estate of J. Neal, with actinolite and magnetite, and at Lisbon, near Mink Pond, in mica slate with staurolite; at Grafton, ½ to 1 in. in diameter. In *Vermont*, at New Fane, large crystals in chlorite slate: also at Cabot and Cavendish. In *Mass.*, at Carlisle, geodes of transparent cinnamon-brown crystals similar to figure 14, with scapolite in limestone; at Boxborough, similar but less remarkable specimens; also in gneiss at Brookfield and Brimfield; massive with epidote at Newbury, and in crystals at Bedford, Chesterfield, with the Cummington kyanite, and at the beryl locality of Barre. In *Conn.*, trapezohedrons, ¼—1 in., in mica slate, at Reading and Monroe; at Haddam, ib. of manganesian garnet, often 2 in. through, with chrysoberyl; at Middletown feldspar quarry, with octahedral faces (Shepard); at Lyme, large blackish-brown crystals in limestone. In *N. York*, in mica slate, in Dover, Duchess Co., small; at Roger's Rock, crystallized and massive, and colophonite of yellow, brown, and red colors, abundant; brown crystals at Crown Point, Essex Co.; colophonite as a large vein in gneiss at Willsboro, Essex Co., with wollastonite and green coccolite, and also at Lewis, 10 m. south of Keeseville; in Middletown, Delaware Co., large brown cryst.; a cinnamon variety, crystallized and massive, at Amity; on the Croton aqueduct, near Yonkers, in small rounded crystals, and a beautiful massive variety—the latter, when polished, forms a beautiful gem. In *N. Jersey*, at Franklin, black, brown, yellow, red, and green dodecahedral garnets; also near the Franklin furnace. In *Penn.*, in Chester Co., at Pennsbury, fine dark brown crystals with polished faces, in granite; near Knauertown, at Keims' mine, in handsome lustrous crystals, at Chester, brown;

in Concord, on Green's Creek, resembling pyrope; in Leiperville, red; at Mineral Hill, fine-brown at Warren, black. In *Delaware*, cinnamon-stone in trapezohedrons, at Dickson's quarry, 7 m. from Wilmington. Also at Knife rapids on the Mississippi In *California*, green with copper ore, Hope Valley, El Dorado Co., on Rogers' claim; also with copper ore in Los Angeles Co., in Mt. Meadows; ouvarovite, in crystals on chromite, at New Idria; in *Alaska*, in large trapezohedrons, near Stickeen river; pyrope, near Santa Fé, New Mexico.

In *Canada*, at Marmora, dark-red; at Grenville, a cinnamon-stone; an emerald-green chrome-garnet, containing 6 to 7 p. c. of oxyd of chrome, in Orford, Canada, in granular masses and druses of minute transparent dodecahedral crystals, with millerite and calcite (anal. 82); and in the same vicinity large cinnamon-red and yellowish crystals of garnet along with pyroxene.

The cinnamon-stone from Ceylon (called hyacinth) and the precious garnet are used as gems when large, finely colored, and transparent. The stone is cut quite thin, on account of the depth of color, with a pavilion cut below, and a broad table above bordered with small facets. An octagonal garnet measuring 8½ lines by 6½ has sold for near $700. Pulverized garnet is sometimes employed as a substitute for emery.

Alt.—Garnets containing protoxyd of iron often become rusty and disintegrated through the oxydation of the iron, and sometimes are altered, more or less completely, to *limonite*, *magnetite*, or *hematite*. The action of waters containing traces of carbonic acid and carbonates and silicates in solution, results in the same changes nearly as with pyroxene, producing at different times a loss, or alteration, of bases, or by a further change and the addition of water, *steatite*, *serpentine*, *chlorite*. The lime in the lime garnets may be taken up by the carbonic acid of the waters; and if magnesia is combined with the carbonic acid (forming a bicarbonate), it may take the place of the lime, and thus give rise to a *serpentine* or *steatite* pseudomorph, or to a *chlorite*, if the iron partly remains. Alkaline carbonates seldom produce the changes, for alkaline pseudomorphs are rare. An excess of silica is to be expected in analyses, according to Bischof, since part of the bases are often lost through incipient change. Quartz also occurs with the form of garnet.

Trollé Wachtmeister found in a crystallized, reddish-brown garnet, having G.=3·851, from Klemetsaune in Norway, which was partly penetrated by a whitish mineral, $\ddot{\mathrm{Si}}$ 52·11, $\ddot{\bar{\mathrm{Al}}}$ 18·03, $\dot{\mathrm{Fe}}$ 23·54, $\dot{\mathrm{Mn}}$ 1·74, $\dot{\mathrm{Ca}}$ 5·77=101·19, in which there is a deficiency of bases, or what is equivalent, an excess of silica, the oxygen ratio of bases and silica being 1 : 1·7, instead of 1 : 1. Schill found in a melanite from Kaiserstuhl, $\ddot{\mathrm{Si}}$ 45·80, $\ddot{\bar{\mathrm{Al}}}$ 11·00, $\ddot{\bar{\mathrm{Fe}}}$ 12·33, $\dot{\mathrm{Ca}}$ 22·10, $\dot{\mathrm{Mg}}$ 2·00, $\dot{\mathrm{Fe}}$ 7·16, $\dot{\mathrm{Mn}}$ 0·70 =101·09, giving for the oxygen ratio of bases and silica 1 : 1·34. Sthamer obtained for a massive garnet, of a dark grayish-green color, from Miask, having a serpentine-like nucleus, $\ddot{\mathrm{Si}}$ 46·11, $\ddot{\bar{\mathrm{Al}}}$ 12·09, $\ddot{\bar{\mathrm{Fe}}}$ 13·19, $\dot{\mathrm{Ca}}$ 20·33, $\dot{\mathrm{Mg}}$ 7·36=99·08, giving for the oxygen ratio of bases and silica 1 : 1·3.

Pyrope occurs altered to talc at its several localities. A serpentine pseudomorph after garnet, from Schwarzenberg in Saxony, afforded Kersten $\ddot{\mathrm{Si}}$ 34·24, $\dot{\mathrm{Mg}}$ 33·28, $\dot{\mathrm{Fe}}$ 3·38, $\dot{\mathrm{Mn}}$ 0·41, $\dot{\mathrm{Na}}$ 0·35, $\dot{\mathrm{H}}$ with some bitumen 10·62, magnetic iron 17·50=99·78=82·28 serpentine and 17·50 magnetic iron.

Some garnets effervesce with acids, from the presence of carbonate of lime, which they have received probably through the action of waters holding carbonic acid or bicarbonates in solution, as, for example, a black garnet from Arendal, Norway, which contains both calcite and epidote; and crystals from Tvedestrand, which are wholly calcite within, there being but a thin crust of garnet.

Artif.—Melanite garnets have been obtained in a porous glass proceeding from the fusion of idocrase (Klaproth), and also of a melanite from Frascati (v. Kobell). Miller mentions the occurrence of garnet in crystals as a furnace product. Daubrée and Studer state that crystals of garnet may be made by fusing together the constituents. Mitscherlich has also obtained garnets artificially (Ann. Ch. Phys., lxii. 219).

TRITOMITE of Weibye, a hydrous species, is probably related in composition, as it is in form, to garnet and helvin; it appears to give, although a sesquioxyd silicate, the garnet oxygen ratio 1 : 1. See description under HYDROUS SILICATES.

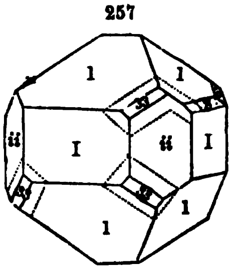
Saualpe.

H.=7·5. G.=4·05—4·75. Lustre adamantine. Colorless, pale yellowish, grayish, yellowish-green, brownish-yellow, reddish-brown. Streak uncolored. Transparent to subtranslucent and opaque. Fracture conchoidal, brilliant. Double refraction strong, positive.

Var.—The colorless and yellowish or smoky zircons of Ceylon have there been long called *jargons* in jewelry, in allusion to the fact that while resembling the diamond in lustre, they were comparatively worthless; and thence came the name *zircon*. The brownish, orange, and reddish kinds were called distinctively *hyacinths*—a name applied also in jewelry to some topaz and light colored garnet. Crystals like fig. 254 are the *engelhardite* of Russia. The crystals from Fredericksvärn, analyzed by Berlin (anal. 5), were by mistake called *Erdmannite*. Minute dark brown and greenish-brown crystals from the chrysoberyl locality at Haddam, Ct., are the *calyptolite* of Shepard, probably an altered variety, like ostranite, malacone, etc. (see beyond). Fig 257 represents, of actual form, a crystal from Warren Co., N. Y., which is chesnut-brown about some of the angles (as marked by dotted lines), and the rest grayish-white; others from the region have stripes of color parallel to the edges of 3-3; the planes 3-3 and 3 are in part wanting.

257



Johnsburg, N. Y.

For crystals from Stockholm G.=4·072—4·222, Svanberg; fr Ilmen Mts., 4·599, 4·610, id.; fr. Ceylon, 4·681, id.; 4·721, Cowry; fr. Fredericksvärn, 4·2, Berlin; from Duncombe Co., N. C., 4·607, Chandler; fr. Litchfield, Me., 4·7, Gibbs; fr.—? 4·615—4·71, Henneberg; fr. Grenville, Canada, 4·625—4·602, T. S. Hunt; fr. Reading, Pa., 4·595. Wetherill.

The crystals have but slight variations in angle. Kokscharof deduced (Min. Russl., iii. 134, 193) for the Ural crystals $1 \wedge 1 = 123° 19' 34''$ and 84° 19′ 46″; which agree very closely with his measurements (123° 20′ 21″) and those for the mineral by Kupffer (Preisschrift, etc.), who obtained 123° 20′ 8″. For the engelhardite Kokscharof obtained 84° 21′ 45″. H. Dauber found for crystals from Miask 123° 20′ 18″ (Pogg., cvii. 275, 1859); from five from Pfitschthal, 123° 20′ 46″; from three crystals fr. Fredericksvärn, 123° 20′ 33″; from a Ceylon crystal, 123° 19′ 50″.

Comp.—$\ddot{\mathrm{Z}}\mathrm{r}\,\dddot{\mathrm{Si}}$=Silica 33, zirconia 67=100. Analyses: 1, Klaproth (Beitr., v. 126); 2, Vauquelin (Haüy's Min., 1801); 3, Berzelius (Ak. H. Stockh., 1824); 4, Wackernagel (Ramm. Min. Ch., 890); 5, Berlin (Pogg., lxxxviii. 162); 6, Henneberg (J. pr. Ch., xxxviii. 508); 7, Vanuxem (J. Ac. Philad., iii. 59); 8, C. F. Chandler (Am. J. Klaproth discovered the earth zirconia in this species in 1789 (Beitr., i. 203).

Pyr., etc.—Infusible; the colorless varieties are unaltered, the red become colorless, while dark-colored varieties are made white; some varieties glow and increase in density by ignition. Not perceptibly acted upon by salt of phosphorus. In powder is decomposed when fused with soda on the platinum wire, and if the product is dissolved in dilute muriatic acid it gives the orange color characteristic of zirconia when tested with turmeric paper. Not acted upon by acids except in fine powder with concentrated sulphuric acid. Decomposed by fusion with alkaline carbonates and bisulphates.

G. before heating of a Ceylon zircon, 4·183, after heating to redness, 4·534, Damour; but for some zircons no change, according to Church; trials, before and after, of the Henderson Co, 4·575, 4·540; another, ib., 4·665, 4·665; the Expailly, 4·863, 4·861; the Fredericksvärn, 4·489, 4·638. A phosphoric glow after heating, and the greatest density after this glow, Church.

Obs.—Occurs in crystalline rocks, especially granular limestone, chloritic and other schists; gneiss, syenite; also in granite; sometimes in iron-ore beds.

Zircon-syenite is a coarse syenitic rock, containing crystals of zircon, with oligoclase, ægirine, elæolite, epidote. Crystals are common in most auriferous sands (p. 6). Sometimes found in volcanic rocks.

Found in alluvial sands in Ceylon; in the gold regions of the Ural, near Miask, Beresovsk, Newjansk, etc.; at Laurvig and Hakedal in Norway; at Arendal in Norway, in the iron-mines, at Fredericksvärn, in zircon-syenite; at Ohlapian in Transylvania; at Bilin in Bohemia; Sebnitz in Saxony; Pfitschthal in the Tyrol, at Expailly, near Le Puy in France; in Auvergne, in volcanic tufa; at Vesuvius, with ryacolite; in Scotland, at Scalpay, Isle of Harris; at Strontian in Argyleshire; in the auriferous sands of the Croghan Kinshela Mtn., Ireland; in Greenland; at Santa Rosa in Antioquia, N. Grenada; in the gold regions of Australia.

In N. America, in *Maine*, at Litchfield; at Mt. Mica in Paris; Greenwood; Hebron. In *Vermont*, at Middlebury. In *Conn.*, at Norwich, with sillimanite, rare; at Haddam (calyptolite) in minute crystals. In *N. York*, at Hall's mine in Moriah, Essex Co., cinnamon-red, in a vein of quartz; near the outlet of Two Ponds, Orange Co., with scapolite, pyroxene, and sphene, in crystals sometimes 1 in. in length; on Deer Hill, 1 m. S.E. of Canterbury, in the same Co., crystals abundant of a deep brownish-red or black color, and occasionally 1½ in. in length; in Warwick, at the southern base of Mount Eve, chocolate-brown crystals in limestone and scapolite; near Amity, and also in Monroe and Cornwall, at several localities, of white, reddish-brown, clove-brown, and black colors; at Diana in Lewis Co., in large brown crystals sometimes 2 in. long, with sphene and scapolite, but rare; in St. Lawrence Co., with apatite, at Robinson's in the town of Hammond, near de Long's Mills, some of the crystals 1½ in. long and ½ in. wide, and occasionally containing a nucleus of carbonate of lime; also at Rossie (form *I*, 1, 3); at Johnsburg, in Warren Co. In *N. Jersey*, at Franklin; at Trenton in gneiss. In *Penn.*, near Reading, in large crystals in magnetic iron ore; at Easton, in talcose slate. In *N. Car.*, in Buncombe Co., on the road from the Saluda Gap to Asheville, upon the first elevation after passing Green river, crystals found loose in the soil, and imbedded in feldspar; in the sands of the gold washings of McDowell Co. (f. 253). In *California*, in the auriferous gravel of the north fork of the American river, and elsewhere. In *Canada*, at Grenville; St. Jerome; Mille Isles.

The name *Hyacinth* was applied by the ancients to a bluish-violet stone, regarded as our sapphire, and was derived from a flower (lily) so-called of this color. [In modern mineralogy a *hyacinth-color* is reddish-orange with a tinge of brown.] Intagli of zircon are common among ancient gems, and the fact that the *lyncurium* of Theophrastus was, as he says, used for engraved signets, while at the same time electric on friction, and often amber-colored, are the principal evidence that it was our zircon.

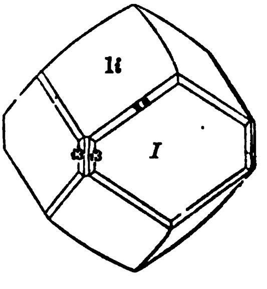
Alt.—Zircon is one of the least alterable of minerals, as it contains no protoxyds, and only the most insoluble of peroxyds. It however passes to a hydrous state, and is attended ultimately with a loss of silica and the addition of oxyd of iron and other impurities derived from infiltrating waters. *Auerbachite*, *malacon*, *œrstedite*, *tachyaphaltite*, *calyptolite*, *cyrtolite*, are probably altered zircon.

The following tetragonal zircon-like minerals are probably altered zircon. They afford B.B. more or less water:

272A. **MALACON.** (Malakon *Scheerer*, Pogg., lxii. 436, 1845.) $1 \wedge 1 = 124° 40'$ to $124° 57'$, and $83° 30'$. H.=6·5. G.=3·9–4·047. Lustre vitreous to subvitreous. Color brown, powder reddish-brown or uncolored. From Hitteröe in Norway; and Chanteloube, Haute Vienne, occurring in thin plates, over 3 to 4 mm. thick, and occasionally with crystals on their surface. Named from *μαλακός*, *soft*.

272B. **CYRTOLITE.** (Malacone, Altered Zircon, *J. P. Cooke*, Am. J. Sci., xliii. 228; Cyrtolite *W. J. Knowlton*, ib., xliv. 224.) Form as in f. 258, with the pyramidal planes convex. H.=5–5·5; after ignition 7–7·5, Cooke. G.=3·98–4·04, Cooke; 3·85, 3·97, Knowlton. Lustre somewhat adamantine. Color brownish-red; powder the same. From Rockport, Mass., in granite, with danalite and cryophyllite. Named from *κύρτος*, *bent*. Fig. 258 from Cooke.

258



A mineral found with columbite at Rosendal, near Björkboda, Finland, has been referred to adelpholite of Nordenskiöld (p. 525), but an analysis by A. E. Nordenskiöld (anal. 7) shows that it is an altered zircon, near malacon or cyrtolite (Œfv. Ak. Stockh., 1863, 452, Pogg., cxxii. 615, 1864).

272C **TACHYAPHALTITE.** (Tachyaphaltit *Weibye*, Pogg., lxxxviii. 160, 1853.) Crystals like those of zircon, with planes *I*, *i-i*, and two octahedrons, one of 110° and the other of 50°. H.=5·5. G.=3·6. Lustre submetallic to vitreous. Color dark reddish-brown. Streak dirty yellow. Subtranslucent. From granite veins in gneiss near Krageröe in Norway, with sphene. Named from *ταχυς*, *quick*, and *αφαλτος*, the mineral flying readily from the gangue when struck. Berlin puts a ? after *thoria* in his analysis (No. 8).

272D. **ŒRSTEDITE.** (Œrstedit *Forchhammer*, Pogg., xxxv. 630, 1835.) $1 \wedge 1 = 123° 16\frac{1}{2}'$. H.=5·5. G.=3·629. Lustre splendent adamantine. Color reddish-brown. From Arendal in Norway, and commonly on crystals of pyroxene. Named after Œrsted.

272E. **Auerbachite.** (Auerbachit *Hermann*, J. pr. Ch., lxxiii. 209, 1858.) 1 ∧ 1=122° 43′ and 85° 21′, Kokscharof; 86° 30′, Herm.; 87°, Auerbach. H.=6·5. G.=4·06. Lustre greasy to vitreous, weak. Color brownish-gray. From a siliceous schist in the Circle of Mariupol, District of Alexandrovsk, Russia. Named after Dr. Auerbach, by whom the crystals were first studied.

272F. **Bragite** (*Forbes & Dahll*, Nyt. Mag. Nat., xiii. 1855). Occurs in imperfect crystals, probably tetragonal, in orthoclase, near Helle, Narestö, Alve, and Askerö, Norway. H.=6–6·5; G.=5·13–5·35; lustre submetallic; color brown; streak yellowish-brown; thin splinters translucent. Heated in glass tube decrepitates strongly and loses water. B B. in the platinum forceps infusible, but becomes yellow; with borax, a glass which is brownish-yellow while hot, but green and finally greenish-yellow on cooling. In salt of phosphorus a skeleton of silica. No analysis has yet been made, and the true relations of the species are doubtful.

Analyses: 1, Scheerer (l. c.); 2, Damour (Ann. Ch. Phys., III. xxiv.); 3, Hermann (J. pr. Chem., liii. 32); 4, J. P. Cooke (l. c.); 5, 6, Knowlton (l. c.); 7, A. E. Nordenskiöld (l. c.); 8, Berlin (Pogg., lxxxviii. 160); 9, Forchhammer (l. c.); 10, Hermann (l. c.):

[a] With some Fe O. [b] With some Ti O^2. [c] With trace of manganese.

In Auerbachite, the only anhydrous kind among the above, the oxygen ratio for the silica and zirconia is 1 : 1½, instead of 1 : 1.

Artif.—Formed in crystals by action of chlorid of silicon on zirconia (Daubrée); by action of fluorid of silicon on zirconia, or of fluorid of zirconium on quartz, beautiful transparent octahedrons resulting (Deville and Caron).

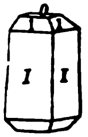
Tetragonal. $O \wedge 1\text{-}i=151°\ 45'$; $a=0·537199$. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}2$, $i\text{-}3$, $i\text{-}\frac{4}{3}$, $i\text{-}\frac{7}{4}$; pyramids, $\frac{1}{20}$, $\frac{1}{10}$, $\frac{1}{9}$, $\frac{1}{8}$, $\frac{1}{7}$, $\frac{1}{6}$, $\frac{1}{5}$, $\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, 1, $\frac{3}{2}$, 2, 3; $\frac{1}{2}\text{-}i$, $1\text{-}i$, $\frac{3}{2}\text{-}i$, $2\text{-}i$, $3\text{-}i$; zirconoids in the zone $i\text{-}i$: 1, 2-2, $\frac{5}{2}\text{-}\frac{5}{2}$, 3-3, $\frac{21}{20}\text{-}\frac{21}{20}$, 4-4, 5-5, 7-7; in other zones, 1-2, $\frac{4}{3}\text{-}2$, 4-2; $\frac{1}{3}\text{-}3$, $\frac{2}{3}\text{-}3$, $\frac{3}{4}\text{-}3$, 1-3, $\frac{3}{2}\text{-}3$; $1\text{-}\frac{7}{4}$, $1\text{-}\frac{7}{3}$.

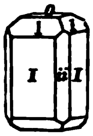
$O \wedge 1=142°\ 46\frac{1}{2}'$	$O \wedge I=90°$	$i\text{-}i \wedge i\text{-}2=153°\ 26'$
$O \wedge 2=123\ 21$	$I \wedge 1\text{-}i=118\ 15'$	$i\text{-}i \wedge i\text{-}3=161\ 34$
$O \wedge 2\text{-}2=129\ 46\frac{1}{2}$	$i\text{-}i \wedge 2\text{-}2=133\ 25\frac{1}{2}$	$1 \wedge 1$, ov. $1\text{-}i$, $=129\ 21$
$O \wedge 4\text{-}4=114\ 18$	$i\text{-}i \wedge 3\text{-}3=144\ 51\frac{1}{2}$	$1 \wedge 1$, ov. I, $=74\ 27$
$O \wedge \frac{3}{4}\text{-}3=139\ 39\frac{1}{2}$	$i\text{-}i \wedge 4\text{-}4=152\ 9$	$1\text{-}i \wedge 1\text{-}i$, pyr., $=140\ 54$

Cleavage: *I* not very distinct, *O* still less so. Columnar structure rare, straight and divergent, or irregular. Sometimes granular massive. Prisms usually terminating in the basal plane *O*; rarely in a pyramid or zirconoid; sometimes the prism nearly wanting, and the form short pyramidal with truncated summit and edges.

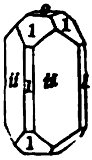
259



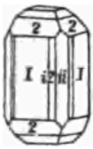
260



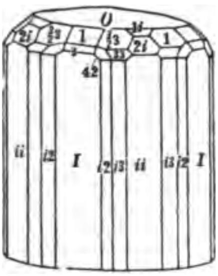
261



262

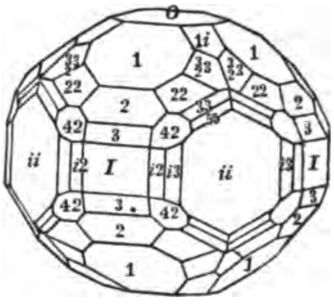


263



Sandford, Me.

264



Vesuvius.

H.=6·5. G.=3·349—3·45. Lustre vitreous: often inclining to resinous. Color brown to green, and the latter frequently bright and clear; occasionally sulphur-yellow, and also pale blue; sometimes green along the axis, and pistachio-green transversely. Streak white. Subtransparent—faintly subtranslucent. Fracture subconchoidal—uneven. Double refraction feeble, axis negative.

Comp., Var.—$(\frac{3}{5}\,\dot{R}^3+\frac{2}{5}\,\bar{R})^2\,\ddot{Si}^3$, the oxygen ratio for the protoxyds, sesquioxyds, and silica being 3 : 2 : 5, according to Rammelsberg, after a determination of the state of oxydation of the iron. The variations from the ratio 3 : 2 : 5 appear to be variations about this as the normal ratio. In all cases the oxygen ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$ is 1 : 1. The bases are mainly alumina for the sesquioxyd, and lime for the protoxyd portion, as in the formula $(\frac{3}{5}\,\dot{Ca}^3+\frac{2}{5}\,\ddot{\bar{A}}l)^2\,\ddot{Si}^3$. But more or less sesquioxyd of iron replaces part of the alumina, and magnesia part of the lime, while $\dot{Mn}$, $\dot{K}$, $\dot{Na}$ may be present in traces.

The species is sometimes divided into (1) *non-magnesian*, containing little or no magnesia; and (2) *magnesian*, the magnesia 4 to 13 p. c. of the mineral. But, as the analyses show, there is no corresponding line of division. Even the crystals from Vesuvius vary in the proportion of magnesia from 0 to 7·11 p. c.

Var. 1. *Ordinary*. The mineral from Gökum in Finland, called *Gahnite*, *Loboite*, *Gökumite*, and that from Frugard, *Frugardite*, have been denominated *magnesian*. The last is in brown and green crystals, with G.=3·349, v. Nord. *Jevreinoffite*, which also is from Frugard, in the parish of Mäntzälä, is but little magnesian or not at all so; it occurs in pale-brown to colorless crystals; G.=3·39. *Heteromerite* occurs in small oil-green prisms, having the planes *I*, *i-i*, 1, 3, 3-3, in the district of Slatoust, Ural. Egeran is a subcolumnar brown variety, from Eger in Bohemia, and found also at Eger in Norway.

Xanthite is a yellowish-brown vesuvianite, from near Amity, N. Y., the crystals not differing from those of the common variety; it contains 2·80 p. c. of protoxyd of manganese. A manganesian variety, from St. Marcel, Piedmont (where ores of manganese occur), has a sulphur to honey-yellow color.

2. *Cyprine*. Pale sky-blue or greenish-blue; owing its color to a trace of copper, whence the name; from Tellemark, Norway.

In analysis 2, G.=3·42; anal. 4, G.=3·399; anal. 14, G.=3·228; anal. 16, G.=3·374; anal. 22, G.=3·42; anal. 23, G.=3·35; anal. 25, G.=3·4; anal. 26, G.=3·221; anal. 27, G.=3·382; anal. 28, G.=3·428–3·429; anal. 29, G.=3·344; anal. 30, G.=3·385; anal. 31, G.=3·378; anal. 32, G.=3·411; anal. 33, G.=3·436; anal. 34, G.=3·384; anal. 35, G.=3·434; anal. 36, G.=3·415; anal. 37, G.=3·407.

Analyses 27–37 were made by Rammelsberg, with special reference to the state of oxydation of the iron. The oxygen ratios thus deduced by him are as follows: (27) 1·3 : 1 : 2·1; (28) 1·5 : 1 : 2·5

(29) 1·5 : 1 : 2·5; (30) 1·6 : 1 : 2·5; (31) 1·5 : 1 : 2·2, (32) 1·3 : 1 : 2·4; (33) 1·4 : 1 : 2·4; (34) 1·3 : 1 : 2·2; (35) 1·3 : 1 : 2·3; (36) 1·9 : 1 : 2·8; (37) 1·5 : 1 : 2·3.

Idocrase often contains some water, amounting occasionally to 3 p. c., the presence of which is probably due to alteration, and hence it is not to be included as part of the protoxyd bases. G Magnus found (Pogg., xcvi. 347) in crystals from Slatoust, 2·44 $\dot{\mathrm{H}}$; from Ala, 2·98 $\dot{\mathrm{H}}$; green from Vesuvius, 0·29; in another, 2·03; brown, id., 1·79. Magnus also obtained a little carbonic acid: 0·15 p. c. from the Slatoust idocrase, and 0·06 from the brown of Vesuvius.

Pyr., etc.—B.B. fuses at 3 with intumescence to a greenish or brownish glass. Magnus states that the density after fusion is 2·93—2·945. With the fluxes gives reactions for iron, and a variety from St. Marcel gives a strong manganese reaction. Cyprine gives a reaction for copper with salt of phosphorus. Partially decomposed by muriatic acid, and completely when the mineral has been previously ignited.

Obs.—Idocrase was first found among the ancient ejections of Vesuvius and the dolomitic blocks of Somma. It has since been met with most abundantly in granular limestone; also in serpentine, chlorite schist, gneiss, and related rocks. It is often associated with lime-garnet and pyroxene. It has been observed imbedded in opal.

At Vesuvius it is hair-brown to olive-green, and occurs with garnet, mica, nephelite, glassy feldspar, etc.; at Ala, in Piedmont, it is in transparent green or brown brilliant crystals, in chlorite schist, with diopside, ripidolite, etc. Found also at Monzoni in the Fassa Valley; at Egg, near Christiansand, Norway; on the Wilui river, near L. Baikal (sometimes called *wiluite*, like the garnet of the same region); Cziklowa in Hungary; in the Urals and elsewhere at localities above mentioned.

In N. America, in *Maine* at Phippsburg and Rumford, just below the falls, in crystals and massive with yellow garnet, pyroxene, etc., in limestone; at Parsonsfield, with the same materials, abundant; at Poland and Sandford (fig. 263). In *Mass.*, near Worcester, in a quartz rock, with garnet, but exhausted. In *N. York*, ¼ m. S. of Amity, grayish and yellowish-brown crystals, sometimes an inch in diameter, in granular limestone; also at the village, and a mile east of the village, of yellow, greenish-yellow, and yellowish-brown colors. In *N. Jersey*, yellowish-brown in crystals at Newton, with corundum and spinel. In *Canada*, at Calumet Falls, in large brownish-yellow crystals in limestone with brown tourmaline; at Grenville in calcite, in wax-yellow crystals.

For recent articles on *cryst.*, see v. Kokscharof's Min. Russl., i. 92, ii. 192; v. Zepharovich, Ber. Ak. Wien, xlix. 6, 1864, both with new measurements and figures, and the latter a complete monograph. Mohs found $O \wedge 1 = 142° 53'$; v. Kokscharof, for crystals from the Urals and Piedmont, 142° 46′ 10″, and from Vesuvius, 142° 46′ 32″; v. Zepharovich, for crystals from Findel Glacier at Zermatt, Pfitsch, and Vesuvius, 142° 47′ 26″; for brown var. from Mussa, and cryst. from Rymfischweng at Zermatt, 142° 46′ 18″; for green var. from Mussa, 142° 45′ 29″, and this last he takes as the normal angle of the species. It gives $a = 0·537541$.

Named *Vesuvian* by Werner, from the first known locality. Werner supposed the mineral to be exclusively volcanic; but as this idea is not expressed, the name is no more objectionable than all others derived from the names of localities. The earlier name, *Hyacinthine*, is bad, as the mineral is not the hyacinth of either ancient or modern time. Haüy's later name, *Idocrase* (subjective, like many others of his) is from εἴδω, *I see*, and κρᾶσις, *mixture*, in allusion to a resemblance between the crystalline forms and those of other species. Nothing in its signification, or in anything else, makes it right to substitute this for Werner's name. In English, the word *vesuvian* has the objection of being an adjective in form and use; but this is avoided by giving it the mineralogical termination above employed.

Alt.—Alterations nearly as in garnet, with a far greater tendency to becoming hydrated. Crystals from Maine often have the exterior, though still brilliant and glassy, cleavable easily from the part below, and equally so, parallel to all the smaller as well as larger faces, so that a pealed crystal has as brilliant and even planes as before. Pseudomorphs include steatite, mica, clinochlore, diopside, and garnet.

An egeran, analyzed by Ficinus (Schrift. Dresd. Min. Ges., i. 235), gave Silica 43·00, alumina 14·70, sesquioxyd of iron 2·40, ib. of manganese 4·00, lime 30·00, soda 5·33 = 99·43. It is probably in an altered state, as Rammelsberg infers from the description of Ficinus.

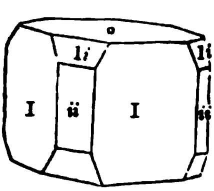
The carbonic acid detected by Hermann in idocrase from Slatoust (anal. 28) is evidence of alteration, and this acid and alkaline or earthy carbonates or bicarbonates in solution, are agents by which change is often produced.

Artif.—Mitscherlich has obtained idocrase by artificial methods (Ann. Ch. Phys., lvii. 219); Studer, from a fusion together of the constituents; also Daubrée, by the action of chlorid of silicon in vapor on the required bases (C. R., 1854, July, p. 135).

274. MELILITE. Mélilite *Delameth.*, T. T., ii. 273, 1796; *Fl. Bellevue* (its discov. in 1796), J. de Phys., li. 456, 1800. Humboldtilite *Mont. & Cov.*, Prodr., 375, 1822. Somervillite *Brooke*, Ed. J. Sci., i. 185, 1824. Zurlite *Ramondini*, Breislak Inst. Geol., iii. 210, 1818. Mellilite.

Tetragonal; $O \wedge 1\text{-}i = 147° \; 15'$; $a = 0{\cdot}6432$. Observed planes, O, I, $i\text{-}i$, $1\text{-}i$, $i\text{-}2$. $1\text{-}i \wedge 1\text{-}i$, over $i\text{-}i, = 65° \; 30'$, $1\text{-}i \wedge 1\text{-}i$, over terminal edge, $= 134° \; 48'$. Fig. 265; also others with planes $i\text{-}2$ in place of $i\text{-}i$. Cleavage: O distinct, I indistinct.

265



H. = 5. G. = 2·9—3·104. Lustre vitreous, inclining to resinous on a surface of fracture. Color white or pale yellow, honey-yellow, greenish-yellow, reddish-brown, brown. Translucent, and in thin laminæ transparent; also opaque. Fracture conchoidal—uneven. Double refraction weak, axis negative.

Comp.—$(\frac{2}{3}\dot{R}^3+\frac{1}{3}\bar{R})^2\ddot{Si}^3$. Analyses: 1, v. Kobell (Schw. J., lxiv. 293); 2–4, Damour (Ann. Ch. Phys., III. x. 59); 5, v. Kobell (Kastn. Arch., iv. 318):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$
1. *Humb.*, Somma	43·96	11·20	——	6·10	31·96	4·28	0·38, $\dot{\text{Fe}}$ 2·32=100·20 Kobell.

3. *Mel.*, C. di Bove	39·27	6·42	10·17	6·44	32·47	1·95	1·46—98·18 Damour; G. 2·95.
4. " "	38·34	8·61	10·02	6·71	32·05	2·12	1·51=99·36 Damour.
5. *Massive Gehlenite*	39·80	12·80	2·57	4·64	37·64	——	0·30, $\dot{\text{H}}$ 2·00=99·75 Kobell.

No. 3, yellow crystals; No. 4, brown do. The massive gehlenite of v. Kobell comes under the formula of melilite. Melilite was first analyzed (but incorrectly) by Carpi in 1820 (Tasch. Min., xiv. 219).

Pyr., etc.—B.B. fuses at 3 to a yellowish or greenish glass. With the fluxes the reaction for iron. Decomposed by muriatic acid with gelatinization.

Obs.—*Humboldtilite* occurs in cavernous blocks of Somma with greenish mica, the crystals often rather large, and covered with a calcareous coating; less common in transparent lustrous crystals with nephelite, sarcolite, and pyroxene, lining cavities in the rock.

Melilite (fr. μελι, *honey*), of yellow and brownish colors, is found at Capo di Bove, near Rome, in leucitophyre with nephelite, phillipsite, gismondite, magnetite, and small black crystals of angite and hornblende; $O \wedge 1\text{-}i = 147° \; 9'$, v. Rath (ZS. G., xviii. 544). *Somervillite*, which Descloizeaux has shown to have the angles of this species, is found at Vesuvius in dull yellow crystals.

Zurlite occurs in opaque square or octagonal prisms in calcareous blocks of Somma with humboldtilite; color whitish or asparagus-green; H. about 6; G.=3·27; B.B. infusible; soluble in nitric acid. It is impure humboldtilite (Scacchi, Jahrb. Min., 1853, 261). Named after Sign. Zurlo.

Named from μελι, *honey*, in allusion to the color.

Artif.—Common as a furnace slag, having been observed in square prisms at Russel's Hall, Tipton, Dowles, Wicks, etc., in England and Wales, near St. Etienne in France, near Charlevoi in Belgium, Königshütte in Upper Silesia, Mägdesprung in the Harz, and Easton, Pa. The following are analyses: 1, 2, Percy (Rep. Brit. Assoc., 1846, Am. J. Sci., II. v. 127); 3, Karsten (Eisenhütt., iii. 679):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{K}}$	Ca S
1. Dudley	38·76	14·48	1·18	0·23	6·84	35·68	1·11	0·98=99·26 Percy.
2. Charlevoi	37·91	13·01	0·93	2·79	7·24	31·43	2·60	3·65=99·56 Percy.
3. Königsberg	39·60	12·60	*tr.*	4·30	——	42·85	——	S 0·65=100 Karsten.

275. SPHENOCLASE. Sphenoklas *v. Kob.*, J. pr. Ch., xci. 348, 1864.

Massive, with faint indications of a foliated structure.

H.=5·5—6. G.=3·2. Lustre feeble. Color pale grayish-yellow. Subtranslucent. Fracture splintery.

Comp.—According to an analysis by v. Kobell (l. c.):

$\ddot{\text{Si}}$ 46·08 $\bar{\text{Al}}$ 13·04 $\dot{\text{Fe}}$ 4·77 $\dot{\text{Mn}}$ 3·23 $\dot{\text{Mg}}$ 6·25 $\dot{\text{Ca}}$ 26·50=99·87.

Giving the O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, 11·81 : 6·10 : 24·57, or 2 : 1 : 4, v. Kobell.

Pyr., etc.—In the closed tube yields no water. B.B. fuses easily (at 3) and quietly to a shining greenish glass. Slightly attacked by muriatic and sulphuric acids; but after heating, easily decomposed with gelatinization by muriatic acid.

Obs.—From Gjellebäck in Norway, with wollastonite and the so-called edelforsite, forming thin layers of varying thickness in a bluish granular limestone.

Named from *σφήν*, *a wedge*, and *κλάω*, *I break*, it breaking into wedge-shaped pieces.

EPIDOTE GROUP.

The species of the Epidote Group, enumerated with the formulas on p. 251, are characterized by specific gravity above 3, and therefore high; hardness above 5; fusibility B.B. below 4; anisometric crystallization, and therefore biaxial polarization; the dominant prismatic angle 112° to 117°; fibrous forms, when they occur, always brittle; colors white, gray, brown, yellowish-green, and deep green to black, and sometimes reddish.

The prismatic angle in zoisite and other orthorhombic species is *I* ∧ *I*; but in epidote it is the angle over a horizontal edge between the planes *O* and *i-i*, the orthodiagonal of epidote corresponding to the vertical axis of zoisite, as explained under the latter species.

T. S. Hunt has observed (C. R., 1863, Am. J. Sci., II. xxxvi. 426, xliii. 205) that the high specific gravity and hardness of the Epidote group, as compared with the Scapolite, is to be ascribed to a more elevated or higher multiple equivalent, or, in other words, to a more condensed molecule. But the numerical value of the multiple, or of the relation between the species, has not yet been ascertained.

Crystals usually lengthened in the direction of the orthodiagonal, or parallel to *i-i*; sometimes long acicular. Cleavage: *i-i* perfect; 1-*i* less so. Twins: composition-plane 1-*i*; also *i-i*. Also fibrous, divergent, or parallel; also granular, particles of various sizes, sometimes fine granular, and forming rock-masses.

H.=6–7. G.=3·25–3·5. Lustre vitreous, on *i-i* inclining to pearly or resinous. Color pistachio-green or yellowish-green to brownish-green, greenish-black, and black; sometimes clear red and yellow; also gray and grayish-white. Pleochroism often distinct, the crystals being usually least yellow in a direction through 1-*i*. Streak uncolored, grayish. Subtransparent—opaque: generally subtranslucent. Fracture uneven. Brittle. Double refraction strong: optic-axial plane *i-i*.

Var.—Epidote has ordinarily a peculiar yellowish-green (pistachio) color, seldom found in other minerals. But this color passes into dark and light shades—black on one side, and brown on the other. Most of the brown and nearly all the gray epidote belongs to the species *Zoisite;* and the reddish-brown or reddish-black, containing much oxyd of manganese, to the species *Piedmontite*, or Manganepidote; while the black is mainly of the species *Allanite*, or Cerium-epidote.

Var. 1. *Ordinary*. Color green of some shade, as described. (*a*) In crystals. (*b*) Fibrous. (*c*) Granular massive. (*d*) *Scorza* is epidote sand, of the usual green color, from the banks of the Arangos, near Muska in Transylvania. The Arendal epidote (*Arendalite*) is mostly in dark green crystals; that of Dauphiny (*Thallite*, *Delphinite*, *Oisanite*) in yellowish-green crystals, sometimes transparent, and found near Bourg d'Oisans, in the Piedmontese Alps. *Puschkinite* includes pleochroic crystals from the auriferous sands of Katharinenburg, Urals; G.=3·066; color emerald-green, when viewed by transmitted light through 1-*i*, yellow transverse to this; named after Puschkin, a Russian senator. *Achmatite* is ordinary epidote, in crystals, from Achmatovsk, Ural. *Escherite* is a brownish-yellow, somewhat greenish epidote, from St. Gothard (anal. 28).

2. The so-called *Bucklandite* from Achmatovsk, described by Hermann (anal. 41, 42), is black with a tinge of green, and differs from ordinary epidote in having the crystals nearly symmetrical, and not, like other epidote, lengthened in the direction of the orthodiagonal. G.=3·51. Hermann's *Bagrationite*, from Achmatovsk, appears to be essentially the same mineral, it agreeing with it in angles, according to Hermann (Bull. Soc. Nat. Moscow, xxxv. 248, 1862), and having G.=3·46, while the original bagrationite of Kokscharof is a variety of allanite (q. v.). It differs from the bucklandite in containing a little cerium (anal. 43).

3. *Withamite*. Carmine-red to straw-yellow: strongly pleochroic; the color as seen through in one direction, deep crimson, in another transverse, straw-yellow; H.=6–6·5; G.=3·137; in small radiated groups, *i-i* ∧ -1-*i*=116°, -1-*i* ∧ 1-*i*=128° 20′. From trap, at Glencoe, in Argyleshire, Scotland. Named after Dr. Witham.

4. *Beustite*. Grayish-white to ash-gray; G.=2·859–2·877, Breith. Breithaupt gives the angle *T* ∧ *P*=154° 20′, *M* ∧ *P*=110° 30′, which are very near *O* ∧ 1-*i*, and -2-*i* ∧ 1-*i*. From near Predazzo in the Tyrol.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$=1 : 2 : 3; $(\frac{1}{3}\dot{\mathrm{C}}\mathrm{a}^3+\frac{2}{3}(\bar{\mathrm{F}}\mathrm{e}, \bar{\mathrm{A}}\mathrm{l}))^2\ddot{\mathrm{Si}}^3$; being *lime-iron-epidote*, the mineral having for its protoxyd portion almost solely lime ($\dot{\mathrm{C}}\mathrm{a}$), but containing sesquioxyd of iron ($\bar{\mathrm{F}}\mathrm{e}$) in place of part of the alumina ($\bar{\mathrm{A}}\mathrm{l}$). The results of the larger part of the analyses conform nearly to the above ratio, showing apparently that it is the *normal* ratio. Several appear to afford, according to Hermann, less $\bar{\mathrm{R}}$ and $\ddot{\mathrm{Si}}$ in proportion to the $\dot{\mathrm{R}}$, giving different ratios between 1 : 2 : 3 and 1 : 1½ : 2½; but with the sum of the oxygen of the protoxyds and sesquioxyds always equal to that of the silica. The exact condition of the iron, whether part is protoxyd or not, has not in all cases been ascertained, and, therefore, some of the results obtained are not free from doubt. Rammelsberg observes that when this point is cleared up the ratio 1 : 2 : 3 will probably be found to be common to all.

The Achmatovsk "bucklandite" (anal. 41, 42) gives nearly the ratio 2 : 3 : 5; but if the iron be all sesquioxyd, 1 : 2·1 : 2·9. Rammelsberg says the crystals may contain some magnetite.

The ratio of F̶e to A̶l in most epidote is approximately 1 : 2, as in analyses 1 to 18, 20, 22–31, 33, 39; but other ratios occur between 1 : 2 and 1 : 6; and rarely the amount of F̶e is so large as to give nearly the ratio 3 : 5. Ratio 1 : 2½ is afforded by analysis 19; 1 : 3 by 32; 1 : 4 by 24–26 28–30; 1 : 5 by 27; 1 : 6 by 23. In analysis 40, the silica is much below the usual proportion, and the O. ratio for Ṙ, R̶, S̈i is nearly 3 : 4 : 6.

ᵃ Anal. on material after its ignition; some Ti O^2 with the Si O^2

In anal. 5, G.=3·37; anal. 6, G.=3·49; anal. 8 has the form of pyroxene; anal. 9, G.=3·223, has the form of scapolite; anal. 11, G.=3·38; anal. 12, G=3·463, material analyzed after its ignition; anal. 16, G.=3·42; anal. 23, G.=3·361—3·316, in the Grisons; 24, 3·373; 26, G.=3·326; 27, 3·359, Borderrheinthal: 3·384, from Maggiathal; 29, 3·378, from Formazzathal; 30, 3·369, Vorderrheinthal; 31, 3·43; 32, 3·33—3·34; 33, 3·485; 34, 3·39; 35, 3·41; 36, 3·35; 37, G.=3·43, fr. Werchneivinsk; 39, 3·45, near Helsingfors; 40, 3·51; 42, 3·46.

Pyr., etc.—In the closed tube gives in most cases water. B.B. fuses with intumescence at 3–3·5 to a dark brown or black mass which is generally magnetic. Reacts for iron and sometimes for manganese with the fluxes. Partially decomposed by muriatic acid, but when previously ignited, gelatinizes with acid. Decomposed on fusion with alkaline carbonates. G. of Arendal epidote changes on ignition, from 3·409 to 2·984

Obs.—Epidote is common in many crystalline rocks, as syenite, gneiss, mica schist, hornblendic schist, serpentine, and especially those that contain the ferriferous mineral hornblende. It often accompanies beds of magnetite or hematite in such rocks. It is sometimes found in geodes in trap; and also in sandstone adjoining trap dikes, where it has been formed by metamorphism through the heat of the trap at the time of its ejection. It also occurs at times in nodules in different quartz-rocks or altered sandstones. It is associated often with quartz, pyroxene, feldspar, axinite, chlorite, etc., in the Piedmontese Alps.

It sometimes forms with quartz an epidote rock, called *epidosyte*. Such a rock, from Grand Matanne River, Canada, having a hardness of 7·0, and G.=3·04, gave T. S. Hunt, on analysis (Logan's Rep., 1863, 497), $\ddot{\mathrm{Si}}$ 62·60, $\dddot{\bar{\mathrm{Al}}}$ 12·30, $\dddot{\bar{\mathrm{Fe}}}$ 9·40, $\dot{\mathrm{Mg}}$ 0·72, $\dot{\mathrm{Ca}}$ 14·10, $\dot{\mathrm{Na}}$ 0·43, ign 0·19=99·71, which corresponds to 61·33 epidote and 38·22 quartz. A similar rock exists at Melbourne in Canada.

Beautiful crystallizations come from Bourg d'Oisans, Ala, and Traversella, in Piedmont; Zermatt in the Valais; near Gutanen in the Haslithal; at Kaverdiras and Baduz in the valley of Tavetsch (the latter sometimes referred to zoisite, but optically epidote according to Descloizeaux); Monzoni in the Fassa valley; Zillerthal in the Tyrol, sometimes in rose-red and greenish crystals of small size, resembling *thulite*; the Sau-Alpe in Carinthia; and the other localities mentioned above.

In N. America, occurs in *N. Hamp.* at Franconia, crystallized and granular, with magnetite; Warren, with quartz and pyrite. In *Mass.*, at Hadlyme and Chester, in crystals in gneiss; at Athol, in syenitic gneiss, in fine crystals, 2 m. S.W. of the centre of the town; Newbury, in limestone; at Rome, in hornblende schist; at Nahant, poor, in trap. In *Rhode Island*, at Cumberland, in a kind of trap. In *Conn.*, at Haddam, in large splendid crystals. In *N. York*, 2. m. S.E. of Amity, in quartz; 2 m. S. of Carmel, Putnam Co., with hornblende and garnet; 2 m. S. of Coffee's Monroe, Orange Co.; 6 m W. of Warwick, pale yellowish-green, with sphene and pyroxene; at Harlem, in gneiss, on the banks of East river, near 38th St. In *N. Jersey*, at Franklin, massive; at Roseville in Byram township, Sussex Co., in good crystals. In *Penn.*, at E. Bradford. In *Michigan*, in the Lake Superior region, at many of the mines; at the Norwich mine, beautifully radiated with quartz and native copper. In *Canada*, at St. Joseph, in a concretionary argillaceous rock of the Quebec group.

For recent papers on cryst. see Kokscharof Min. Russl., iii. 268, iv. 106; v. Zepharovich, Ber. Ak. Wien, xxxiv. 480, xlv. 381; Descl. Min, i. 1862; Hessenberg, Min. Not., III.; v. Rath, Pogg., cxv. 472.

Epidote is one of Haüy's crystallographic names, derived from the Greek ἐπίδοσις, *increase*, and translated by him, "qui à reçu un accroissement," the base of the prism (rhomboidal prism) having one side longer than the other. In its introduction Haüy set aside three older names. Thallite (from θαλλός, color of young twigs, alluding to the green color) was rejected because it was based on a varying character, color; *Delphinite* and *Arendalite*, because derived from localities. But the name *Epidote* is now so involved in geological as well as mineralogical literature that the law of priority cannot well do the justice demanded of it. Werner's name *Pistacite* from πιστάκια, *the pistachio-nut* (referring to the color) was not proposed as early as thallite or epidote.

Alt.—Epidote is less liable to alteration than most of the silicates, partly because the iron it contains is mostly, when not wholly, in the state of sesquioxyd. The analyses afford generally one or two per cent. of water, which is probably foreign to the species; and in a green mineral from Isle Royale, having the composition of epidote, J. D. Whitney found 5 per cent. of water (Rep. Geol. L. Sup., 1851, 97).

Artif.—Epidote has not been found among the crystallizations of furnace slags, or formed in the laboratory of the chemist. It has been a frequent result of the action of heat and steam on ferruginous sandstones accompanying the ejection of doleryte and other eruptive rocks; and this fact suggests the method by which it may be artificially formed.

276A. KŒLBINGITE. (Kölbingit *Breith.*, B.H. Ztg., xxiv. 398. Ainigmatit *Breith.*, ib.) Monoclinic. $I \wedge I = 66°\ 31'$, $O \wedge i\text{-}i = 59°$. Cleavage: I perfect; i-i imperfect; i-i in traces.

H.=5·5–6. G.=3·599, 3·609, 3·613. Lustre vitreous. Color greenish to velvet black Streak pistachio-green. Subtranslucent. Fracture conchoidal to uneven.

Comp.—Consists, according to R. Müller (l. c.), largely of the silicates of protoxyd of iron and lime.

Obs.—Occurs at Kangerdluarsuk, Greenland, with ægirite, eudialyte, etc., and resembles much a black hornblende. Unlike hornblende and the related species, the crystal is oblique from an acute edge (as in epidote), and the angles of the prism are very different. Arfvedsonite differs in having a celandine-green streak; and ægerite a mountain-green. It may be epidote.

Ænigmatite has the form and angles of kœlbingite; but H.=5—5·5; G.=3·833—3·863; the iron in the compound is sesquioxyd; and the streak is reddish-brown. Probably altered kœlbingite.

277. **PIEDMONTITE.** Röd Magnesia (fr. Piedmont) *Cronst.*, Min., 106, 1758. Manganèse rouge (id.) *Napione*, Mem. Ac. Turin, iv., 1790. Manganèse oxydé violet silicifère (id.) *H.*, Tr., iv., 1801. Epidote manganésifère (id.) *L. Cordier*, J. d. M., xiii. 135, 1803; *H.*, Tabl., 1809. Piemontischer Braunstein *Wern.*, Hoffm. Min., iv. a, 152, 1817. Manganepidot *Germ.* Piemontit *Kenng.*, Min., 75, 1853.

Monoclinic; like epidote in form, and nearly so in angles. *i-i* ∧ –1-*i*= 115° 20′, –1-*i* ∧ ½-*i*=98° 50′, *i-i* ∧ ½-*i*=145° 37′. Cleavage *i-i* perfect, –1-*i* less so. Also massive.

H.=6·5. G.=3·404, Breithaupt. Lustre vitreous, especially bright on *i-i*; slightly pearly on other faces. Color reddish-brown and reddish-black; in very thin splinters columbine-red. Streak reddish. Opaque to subtranslucent. Fragile.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{\mathrm{Si}}=1:2:3$; $(\frac{1}{3}\dot{\mathrm{C}}\mathrm{a}^3+\frac{2}{3}(\bar{\mathrm{Mn}}, \bar{\mathrm{Fe}}, \bar{\mathrm{Al}}))^2\ddot{\mathrm{Si}}^3$; or epidote in which a large part of the alumina is replaced by sesquioxyd of manganese. The protoxyds may also include some protoxyd of manganese as well as magnesia.

Analyses: 1, Sobrero (Arsb., 1840, 218); 2, Hartwall (Ak. H. Stockh., 1828, 171); 3, Geffken (Pogg., xvi. 483); 4, H. St. C. Deville (Ann. Ch. Phys., xliii. 13):

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\bar{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$
1. St. Marcel	37·86	16·30	8·23	18·96	——	13·42, $\dot{\mathrm{M}}$n 4·82, $\ddot{\mathrm{S}}$n, $\dot{\mathrm{C}}$u 0·4=100·66 S.
2 "	38 47	17·65	6·60	14·08	1·82	21·65=100·27 Hartwall.
3. "	36·87	11·76	10·34	18·25	——	22·78=100 Geffken.
4. "	37·3	15·9	4·8	19·0	0·2	22·8 =100 Deville.

The last three analyses correspond nearly with the epidote O. ratio, 1 : 2 : 3. The mineral was first analyzed by Napione (l. c.), and next by Cordier (l. c.).

Pyr., etc.—B.B. fuses with intumescence at 3 to a black lustrous glass. Gives strong reactions for manganese with the fluxes, and also for iron. Not decomposed by acids, but when previously ignited gelatinizes with muriatic acid. Decomposed on fusion with alkaline carbonates.

Obs.—Occurs at St. Marcel, in the valley of Aosta, in Piedmont, in braunite with quartz, greenovite, violan, and tremolite. Crystals rather long subrhomboidal prisms, very fragile, and having most of the surfaces dull.

278. **ALLANITE.** Crystallized Gadolinite? (fr. Greenland) *T. Allan*, Tr. R. Soc. Edinb., vi. 345 (read Nov. 1808)=Allanite *Thomson*, ib., 371 (read Nov. 1810); Phil. Mag., xxxvi. 278, 1811. 269

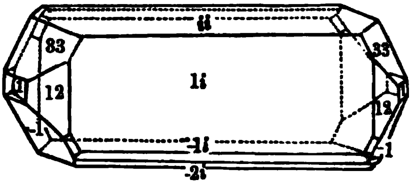
270



Crystals either short, flat tabular, or long and slender, sometimes acicular. Twins like those of epidote. Cleavage: *i-i* in traces. Also massive, and in angular or rounded grains.

H.=5·5—6. G.=3·0—4·2. Lustre submetallic, pitchy, or resinous—occasionally vitreous. Color pitch-brown to black, either brownish, greenish, grayish, or yellowish. Streak gray, sometimes slightly greenish or brownish. Subtranslucent—opaque. Fracture uneven or subconchoidal. Brittle. Double refraction either distinct, or wanting.

Comp., Var.—This species, while closely like epidote in crystallization, varies much in the results of analyses, and also in external appearance. The more prominent ways of variation are the following: (1) The crystals are sometimes broad tabular, and sometimes very long acicular. (2) The crystals, when well-formed, often manifest no double refraction, as Descloizeaux has observed. (3) The amount of water present varies from none to 17 p. c., and the hardness and specific gravity correspondingly, the kinds containing the most water being lowest; and, in some, G. not exceeding 2·53. (4) There is also much diversity in pyrognostic and other chemical characters, as explained beyond.

The varieties that have been distinguished are as follows:

1. *Allanite.* In tabular crystals or plates, the crystals sometimes 8 to 10 in. long, 5 to 6 wide, and an inch or so thick. Color black or brownish-black. G.=3·50—3·95; 3·53—3·54, from Jotun-Fjeld; 3·79, from Snarum, Norway; 3·53, from E. Bradford, Pa., and 3·935, from Bethlehem, Pa., Brush; 3·84, from Franklin, N. J., Hunt. Named after T. Allan, the discoverer of the mineral, and found among specimens from East Greenland, brought to Scotland by C. Giesecké. *Cerine* is the same thing, named by Hisinger, having H.=6; G.=3·77—3·8; lustre weak, greasy; and being subtranslucent in thin splinters.

Bucklandite is anhydrous allanite in small black crystals from a mine of magnetite near Arendal, Norway. Although not yet analyzed, it is referred here by v. Rath on the ground of the angles and physical characters (Pogg., cxiii. 281). That of L. Laach is also shown to have the angles of allanite by v. Rath (l. c.); the angles are those cited above as the angles of the species. *Tautolite* *Breith.*, is also from the trachyte of L. Laach, and is probably the same species. Angles: *i*-2 ∧ *i*-2 = 70° 48′ and 109° 12′, *i-i* ∧ 1-*i*=114° 30′, 1-*i* ∧ 1=125° 30′, −1-*i* ∧ 1-*i*=128° 37′ and 51° 20′. Descl.; *i*-2 ∧ *i*-2=70° 14′, −1-*i* ∧ 1-*i*=51° 52′, Breith. H.=6·5—7. G.=3·86.

2. *Uralorthite* is allanite in large prismatic crystals from the Ilmen Mts., near Miask. H.=6; G.=3·41—3·60, Herm.; 3·647, Ramm. It is pitch-black, gives a gray powder, and is nearly anhydrous.

2. *Bagrationite.* Occurs, according to Kokscharof, in black crystals, which are nearly symmetrical like the bucklandite of Achmatovsk, and not lengthened, like uralorthite, in the direction of the orthodiagonal. Angles the same with those of uralorthite, after many measurements by Kokscharof. H.=6·5. G.=3·84, Koksch. Streak dark brown. B.B. intumesces and forms a black, shining, magnetic pearl. In powder not attacked by hot muriatic acid or by boiling nitric acid. Not analyzed. Named after the discoverer, P. R. Bagration. From Achmatovsk, Ural

Hermann has described and analyzed what he calls *bagrationite*, from Achmatovsk, which he states has the angles of the bucklandite *of Achmatovsk*, and which, therefore, is true epidote (q v.). The analyses by Hermann sustain this reference.

3. *Orthite* included, in its original use, the slender or acicular prismatic crystals, often a foot long, containing some water. But these graduate into massive forms, and some orthites are anhydrous, or as nearly so as much of the allanite. The name is from ὀρθός, *straight*. The tendency to alteration and hydration may be due to the slenderness of the crystals, and the consequent great exposure to the action of moisture and the atmosphere. H.=5—6. G.=2·80—3·75; 3·63—3·65 from Fille-fjeld; 3·546, from Hitteröe, Ramm.; 3·373, Scheerer; 3·69—3·71, from Swampscot, Mass., Balch; 2·86—2·93, from Naes mine, 10 m. E. of Arendal, a hydrous variety containing 12 p. c. of water. Lustre vitreous to greasy

4. *Xanthorthite*, of Hermann, is yellowish and contains much water, and is apparently an altered variety; G.=2·78—2·9. Named from ξανθός, *yellow*, and *orthite*.

5. *Pyrorthite* of Berzelius is an impure orthite-like mineral, in long prisms of rather loose texture, containing as its principal impurity some carbonaceous material (over 30 p. c.), and showing this in its burning before the blowpipe. Named from πυρ, *fire*, and *orthite*. From Kararfvet, near Fahlun.

6. *Erdmannite*, of Berlin, from Stökö, near Brevig, is near orthite in composition. It occurs in imbedded grains and plates, with G.=3·1, lustre vitreous, color dark brown, and is translucent in thin splinters. Named after Prof. Erdmann. Contains 4 to 5 p. c. of water.

Allanite is a *cerium-epidote*. But, besides a large percentage of cerium, it contains generally the related metals, lanthanum and didymium, with also, sometimes, a little yttrium, and rarely traces of glucinum. The condition of oxydation of the iron has not been exactly determined in most of the analyses, and consequently the results are discordant. The best determinations, according to Rammelsberg, afford approximately, the garnet-ratio 1:1:2, instead of the epidote ratio 1:2:3, whence the formula $(\frac{1}{2}\dot{R}^3+\frac{1}{2}\bar{R})^2\ddot{Si}^3$. In this formula $\dot{R}=\dot{Ca}, \dot{Ce}, \dot{La}, \dot{Di}, \dot{Fe}$, with sometimes $\dot{Mg}, \dot{Y}, \dot{Mn}$; and $\bar{R}=\bar{Al}, \bar{Fe}$. Analyses 9–11 gave this oxygen ratio to Genth.

Analyses: I. ALLANITE; 1, Stromeyer (Pogg., xxxii. 288); 2, Credner (Pogg., lxxix. 414); 3, Rammelsberg (Pogg., lxxx. 285); 4, Bergemann (Pogg., lxxxiv. 485); 5, Zschau (Jahrb. Min., 1852, 653); 6, 7, Scheerer (Pogg., li. 407, 465, lvi. 479, lxi. 636); 8, Hermann (J. pr. Ch., xxiii. 273, xliii. 35, 99); 9, 10, 11, P. Keyser (Am. J. Sci., II. xix. 20); 12, T S. Hunt (Proc. N. H. Soc. Boston. viii. 57).

II. *Cerine*; 13, Hisinger (Afh. i. Fys., iv. 327); 14, Scheerer (l. c.); 15, P. T. Cleve (Œfv. Ak. Stockh., xix. 425, 1862, J. pr. Ch., xci. 223); 16, v. Rath (Pogg., cxix. 273); 17, 18, D. M. Balch (Am. J. Sci, II. xxxiii. 348).

III. *Uralorthite*; 19, 20, Hermann (J. pr. Ch., xliii. 102, 105); 21, Rammelsberg (Min. Ch., 746).

IV. *Orthite*; 22, 23, Berzelius (Hisinger's Min. Schwed.); 24, 25, Berlin (Jahresb., xvii. 221), 26, 27, 28, Scheerer (l. c.); 29, C. W. Blomstrand (Œfv. Ak. Stockh., 1854, 296, J. pr. Ch., lxvi. 156); 30, F. Stifft (Jahrb. Min., 1856, 395); 31, D. Forbes (Edinb. N. Ph. J., II. vi. 112); 32, Strecker (Christiania Univ. Programme, 1854, Ed. N. Ph. J., II. vi. 112); 33, Zittel (Ann. Ch. Pharm., cxii. 85).

V. *Xanthorthite*; 34, 35, Bahr and Berlin (Œfv. Ak. Stockh., 1845, 86).

VI. *Erdmannite*; 36, Berlin (Pogg., lxxxviii. 162).

Analysis 1, from Iglorsoit; 2, G.=3·79, from Krux, Thuringia; 3, O. ratio 1 : 1 : 2, from Chester Co., Pa.; 4, from West Point, N. Y.; 5, G.=3·4917, near Dresden; 6, near Jotunfjeld; 7, Snarum; 8, G.=3·48—3·66, from Werchoturie, Ural, the so-called bucklandite; 9, G.=3·782, H.=5·5, pitch-black, no cleavage, from Orange Co., N. Y.; 10, G.=3·831, H.=6, pitch-black, from near Eckhardt's furnace, Berks Co., Pa.; 11, G.=3·491, H.=5, bnh.-bk., Bethlehem, Northampton Co., Pa.; 12, G.=3·84, Franklin, N. J., in magnetic iron.

13, G.=3·77—3·80, Bastnaes; 14, Riddarhyttan; 15, G.=4·108—4·103, O. ratio 4 : 3 : 7; 16, G.=3·983, from L. Laach; 17, 18, G.=3·69—3·71, jet-black, massive, from Swampscot, Mass.

19, 20, G.=3·41—3·647, from Miask, in the Ural; 21, G.=3·647, Miask.

22, G.=3·288, Fahlun; 23, Finbo; 24, 25, G.=3·5, Ytterby; 26, G.=3·63—3·65, Fillefjeld; 27, 28, G.=3·373, Hitteröe; 29, Wexio, Sw.; 30, G.=3·44—3·47, pitch-bk. to bnh.-bk., in syenite near Weinheim; 31, 32, G.=2·86—2·93, gnh.-bk., Naes mine, Norway, in a granite containing both orthoclase and oligoclase; 33, Naes mine, near Arendal; 34, G.=2·78, yellow, Eriksberg; 35, G.=2·88, black, Kullberg; 36, Stökö, in the Langesund fiord, near Brevig, G.=3·1.

Rammelsberg found, on examination, that the Hitteröe orthite contained F̶e 8·16 and Ḟe 8·30, and thus deduced for the mineral the O. ratio 1 : 1 : 2. The cerine of Bastnaes contained, according to Damour, 1·74 p. c. of water.

The *pyrorthite* afforded Berzelius (l. c.) S̈i 10·43, A̶l 3·59, Ḟe 6·08, Ṁn 1·39, Ċe 13·92, Ẏ 4·87, Ċa 1·81, Ḣ 26·50, carbon (by loss) 31·41.

Pyr., etc.—Some varieties give water in the closed tube. B.B. fuses easily and swells up (F.=2·5) to a dark, blebby, magnetic glass. With the fluxes reacts for iron. Most varieties gelatinize with muriatic acid, but if previously ignited are not decomposed by acid.

Obs.—Occurs in albitic and common feldspathic granite, syenite, zircon-syenite, porphyry, white limestone, and often in mines of magnetic iron. *Allanite* occurs in Greenland, in granite; at

Criffel, in Scotland, in small crystals: at Jotun Fjeld in Norway, in a kind of porphyry, and at Snarum, in albite, along with rutile and apatite; at Plauensche Gründ, near Dresden; in granite near Suhl in the Thüringerwald. *Cerine* occurs at Bastnäs in Sweden with hornblende and chalcopyrite. *Orthite* occurs in acicular crystals sometimes a foot long at Finbo near Fahlun, and at Ytterby in Sweden; at Skeppsholm near Stockholm, in black vitreous masses disseminated through gneiss; also at Krageröe, Hitteröe, and Fille Fjeld in Norway; at Miask in the Ural. *Ura'orthite* occurs with small crystals of zircon in flesh-red feldspar at Miask in the Ural.

In *Mass.*, at the Bolton quarry; at St. Royalston, in boulders; in Athol, on the road to Westminster, in gneiss; at Swampscot, near Marblehead. In *Conn.*, at Allen's vein, at the gneiss quarries, Haddam. In *N. York*, near W. Point, in tabular cryst.; Moriah, Essex Co., with magnetite and apatite, some cryst. 8–10 in. long, 6–8 broad, and 1–2 thick; at Monroe, Orange Co. In *N. Jersey*, at Franklin with feldspar and magnetite. In *Penn.*, at S. Mountain, near Bethlehem, in large crystals; at E. Bradford in Chester Co. (called orthite, G.=3·5, anal. 3); at Easton, Northampton Co.; near Eckhardt's furnace, Berk's Co., abundant. In *Canada*, at St. Paul's, C. W.; Bay St. Paul, C. E.; at Hollow lake, head-waters of the S. Muskoka (G.=3·255—3·288, Chapman).

On cryst., see Kokscharof, Min. Russl., iii. 344, iv. 37; v. Rath, Pogg., cxiii. 281, ZS. G., xvi. 254.

Alt.—The hydrous varieties of allanite or orthite are properly altered forms of the species. They often contain carbonic acid. It is probable that the carbonates of lanthanum and of cerium proceed at times from the alteration of allanite.

At Sillböhle, in Finland, there are crystals of allanite having an epidote nucleus, and crystals of epidote having a nucleus of allanite, apparently indicating that a change had taken place from one to the other.

279. MUROMONTITE. *Kerndt*, J. pr. Ch., xliii. 228, 1848.

Amorphous; without any trace of crystallization. In grains. H.=7. G.=4·263. Lustre vitreous or slightly greasy. Color black or greenish-black.

Comp.—Apparently related to allanite, but containing much yttrium, and little aluminum or cerium. Analysis: Kerndt (l. c.):

$\ddot{\text{Si}}$	$\dddot{\overline{\text{Al}}}$	$\dddot{\overline{\text{Be}}}$	$\dddot{\overline{\text{Fe}}}$	$\dot{\text{Mn}}$	$\dot{\text{Ce}}$	$\dot{\text{La}}$	$\dot{\text{Y}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$ & loss.

Obs.—From Mauersberg, near Marienberg, in the Saxon Erzgebirge.
Named from a Latin rendering of Mauersberg.

279A. BODENITE *Breith.*, Pogg., lxii. 273, 1844, *Kersten*, ib., lxiii. 135, *Kerndt*, J. pr. Ch., xliii. 219. Related to muromontite in composition, and in containing more yttrium than cerium, but has a larger percentage of alumina and lime, and no glucina, and is hydrous. Composition according to Kerndt (l. c.):

$\ddot{\text{Si}}$	$\dddot{\overline{\text{Al}}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Ce}}$	$\dot{\text{La}}$	$\dot{\text{Y}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
26·12	10·34	12·05	1·62	10·46	7·57	17·43	6·32	2·34	0·84	1·21	3·82=100.

From Boden, near Marienberg, with muromontite.

279B. MICHAELSONITE *Dana.* An *orthite-like* mineral occurring near Brevig with meliphanite, containing, like muromontite, little alumina and some glucina, afforded Michaelson and Nobel (Œfv. Ak. Stockh., 1862, 505):

	$\ddot{\text{Si}}$	$\dddot{\overline{\text{Al}}}$	$\dddot{\overline{\text{Fe}}}$	$\ddot{\text{Zr}}$	$\dddot{\overline{\text{Be}}}$	$\dot{\text{Ce}}$	$\dot{\text{La}}$, $\dot{\text{Di}}$	$\dot{\text{Y}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{H}}$	
1.	29·21	2·81	6·42	5·44	4·27	9·79	15·60	1·63	0·45	14·93	2·45	5·50	=98·41 Mich.
2	28·80	17·51				11·47	14·12	1·49	*tr.*	16·06	——	——	Nobel.

In anal. 2, Nobel obtained also 0·83 p. c. of a precipitate by means of S H. H.=4–5; G.=3·44; in thin splinters transparent to translucent; lustre vitreous; amorphous. It differs from muromontite in containing but little yttria.

$I \wedge i\text{-}\breve{i} = 121° 40'$, meas.
$I \wedge i\text{-}\breve{2} = 165\ 29$
$i\text{-}\breve{i} \wedge i\text{-}\breve{3} = 151\ 37$
$i\text{-}\bar{i} \wedge i\text{-}\breve{2} = 162\ 51$
$i\text{-}\breve{2} \wedge i\text{-}\breve{2} = 145\ 42$
$i\text{-}\breve{3} \wedge i\text{-}\breve{3}$, front, $= 56\ 46$
$i\text{-}\breve{3} \wedge i\text{-}\breve{3}$, side, $= 123\ 14$
$1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, top, $= 109\ 20$
$1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, top, $= 80\ 3$
$i\text{-}\breve{i} \wedge 1\text{-}\breve{i} = 125\ 20$, meas.
$\frac{1}{2}\text{-}\bar{i} \wedge \frac{1}{2}\text{-}\bar{i} = 120\ 14$
$\frac{1}{4} \wedge \frac{1}{4} = 144\ 57$, Descl.

Figure 272, observed form, the right I and $i\text{-}\breve{2}$, and $i\text{-}\breve{3}$ wanting, and planes on left side of summit nearly obsolete; 271, the normal form as deduced from 272. Crystals, lengthened in the direction of the vertical axis, and vertically deeply striated or furrowed. Cleavage: $i\text{-}\breve{i}$ very perfect. Commonly in crystalline masses longitudinally furrowed. Also compact massive.

H.=6–6·5. G.=3·11–3·38. Lustre pearly on $i\text{-}\breve{i}$; vitreous on surface of fracture. Color grayish-white, gray, yellowish, brown, greenish-gray, apple-green; also peach-blossom-red to rose-red. Streak uncolored. Transparent to subtranslucent. Double refraction feeble; optic-axial plane $i\text{-}\breve{i}$; bisectrix positive, normal to $i\text{-}\bar{i}$; Descl.

Var.—A. LIME-ZOISITE. 1. *Ordinary.* Colors gray to white and brown. $I \wedge I$ in Z. of Saualpe 116° 48′, Breith.; of Moravia, 117° 5′, A. Weisbach, the crystal the rhombic prism I with the planes $i\text{-}\breve{2}$ and $i\text{-}\bar{i}$, and basal cleavage at right angles to I distinct. For Z. of Rauris, G.=3·226, Breith.; of Saualpe, 3·345, id.; of Moravia, 3·336, id.; of Faltigl, 3·381, id.; of Titiribi, N. Grenada, 3·381, id. *Unionite* is a very pure zoisite.

2. *Rose-red*, or *Thulite*. G.=3·124; fragile; dichroism strong, especially in the direction of the vertical axis; in this direction reddish, transversely colorless.

B. LIME-SODA ZOISITE; SAUSSURITE (in part). The original saussurite, from the vicinity of Lake Geneva, is a fine-grained compact zoisite, as shown by Hunt, both by the specific gravity and the composition. G.=3·261, fr. the vicinity of Lake Geneva, de Saussure; 3·365–3·385, Hunt; 3·227, Fikenscher; H.=6·5–7; color pale bluish-green, greenish-gray, to white or nearly so; very tough. Hütlin and Pfaffius have described a saussurite which occurs with serpentine in the Schwarzwald (anal. 28). It was partly altered, and had the low hardness 3·5, with G.= 3·16.

Comp.—A lime-epidote, with little or no iron, and thus differing from epidote. Formula $(\frac{1}{3}\dot{\text{Ca}}+\frac{2}{3}\bar{\text{Al}})^3\ddot{\text{Si}}^2$=Silica 39·9, alumina 22·8, lime 37·3=100. The amount of sesquioxyd of iron varies from 0 to 6·33 p. c.; if much more is present, amounting to a sixth atomically of the protoxyd bases, the compound appears to take the monoclinic form of epidote, instead of the orthorhombic of zoisite.

Saussurite, according to the analyses, has the O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$=1 : 2 : 3½, instead of 1 : 2 : 3, and it appears as if this was another case in which an increase of silica accompanies the increase of alkali in the bases. Both Hunt and Fikenscher's analyses give the O. ratio 2 : 3½ for the sesquioxyds and silica. Hunt's, however, has an excess of protoxyds. In a second analysis by Hunt (see below), the specimen contained mixed talc, amounting to 10 or 12 p. c.; and if the magnesia in the first, and in Fikenscher's, is due in part to talc, this would subtract from the silica; and but a small reduction in this way would make the ratio 1 : 2 : 3.

Analyses: 1, 2, Klaproth (Beitr., iv. 179, v. 41); 3, Rammelsberg (Pogg., c. 133); 4, Bucholz (Gehl. J., i. 200); 5, Geffken (Epid. Anal. Dissert. Jenæ, 1824); 6, Rammelsberg (l. c.); 7, Geffken (l. c.); 8, Hermann (J. pr. Ch., xliii. 35); 9, Stromeyer (Unters., 378); 10, Rammelsberg (l. c.); 11, Richter (Haid. Ber., iii. 114); 12, Rengert (Ramm. Min. Ch., 1020); 13, 14, Rammelsberg (l. c., 751); 15, Bernard (J. pr. Ch., v. 212); 16, Kühn (Ann. Ch. Pharm., lix. 373); 17, Rammelsberg (l. c.); 18, Brush (Am. J. Sci., II. xxvi. 69); 19, Thomson (Min., i. 271); 20, Genth (Am. J. Sci., II. xxxiii. 197); 21, Trippel (ib.); 22, C. Gmelin (J. pr. Ch., xliii.); 23, Berlin (Pogg., xlix. 539); 24, Pisani (C. R., lxii. 100); 25, Boulanger (Ann. d. M., III. viii. 159); 26, T. S. Hunt (Am. J. Sci., II. xxvii. 345); 27, Fikenscher (J. pr. Ch., lxxxix. 456); 28, Hütlin and A. v. Pfaffius (Kenng., Ueb., 1861, 76):

[a] Soda and potash. [b] Made Mn^2O^3 by Berlin.

In anal. 3, G.=3·353; anal. 6, G.=3·361; anal. 10, G.=3·352; anal 13, G.=3·251; 14, G.=3·29; 17, G.=3·341; 18, G.=3·299; 20, G.=3·344, some specimens pinkish; 23, G.=3·34; 24 G.=3·02, H.=6·5; 26, G.=3·3—3·4, H.=7, the mineral from the valley of the Rhone in Switzerland, or the region of L. Geneva; 27, G.=3·227, same loc.; 28, G.=3·16.

Anal. 20 is of the same mineral that was analyzed by Mallet under the name *idocrase* (Am. J Sci., II. xx. 85). In anal 28, 1·13 of the silica was separated as *soluble* silica. Hunt obtained for another specimen of saussurite containing much talc (which was so disseminated through it that separation was impossible) $\ddot{\mathrm{Si}}$ 48·10, $\bar{\mathrm{Al}}$ 25·34, $\bar{\mathrm{Fe}}$ 3·30, $\dot{\mathrm{Ca}}$ 12·60, $\dot{\mathrm{Mg}}$ 6·76, $\dot{\mathrm{Na}}$ 3·55, ign. 0·66=100·31. If all but 3 p. c. of the magnesia (the amount in anal. 26) belonged to the talc, the amount of talc present would be 11 p. c.

Pyr., etc.—B.B. swells up and fuses at 3—3·5 to a white blebby mass. Not decomposed by acid; when previously ignited gelatinizes with muriatic acid.

Obs.—This species was instituted by Werner in 1805, first united to epidote by Haüy and Bernhardi independently in 1806, and separated again from epidote on crystallographic grounds by Brooke, in 1823. Descloizeaux has confirmed Brooke's conclusion by optical examinations, and further has shown that the crystallization is orthometric, instead of clinometric. Thulite is referred to the species by Descloizeaux, together with the lime-epidote from most of the localities mentioned in connection with the analyses. The angle *i*-2̆ ∧ *i*-ī in thulite is near 152°. Brooke remarks upon the isomorphism of the species with euclase.

Zoisite was so named after Baron von Zois, from whom Werner received his first specimens; and *Thulite*, after Thule, an ancient name of Norway.

The original zoisite is that of the Saualpe in Carinthia. Other localities are as mentioned. The gray mineral of Fichtelgebirge in Baireut, was referred here by Bernhardi (l. c., 1806), and both to epidote. Thulite occurs at Souland in Tellemark, in Norway, with bluish idocrase (cyprine), yellowish-white garnet, epidote, and fluorite; also at the iron mine of Klodeberg near Arendal; and at Traversella in Piedmont, forming small veins with talc and actinolite in granite.

Saussurite forms with smaragdite the euphotide of the Alps, a rock which, as a result of glacier action, is widely distributed in boulders over the valley of the Rhone, and the country about Lake Geneva; the boulders, as ascertained by Prof. Guyot, were derived from the chain of the Sassgrat, through the valley of the Sass, and are distributed to a distance of 150 m. from this place of origin. Found also in serpentine, in the Schwarzwald, but more or less altered (anal. 28). Hunt showed that both the very high specific gravity and composition identified the mineral with zoisite. (For other minerals that have passed under the name of saussurite, see Garnet, Meionite, Labradorite.)

In the United States, found in *Vermont*, at Willsboro, in columnar masses; at Montpelier, bluish-gray along with calcite, in mica schist. In *Mass.*, at Chester, in mica schist; at Goshen, Chesterfield, Hinsdale, Heath, Leyden, Williamsburg, Windsor. In *Conn.*, at Milford. In *Penn.*, in W. Bradford and W. Goshen, Chester Co.; in Kennet township and E. Marlboro; at Unionville, white (*Unionite*) with corundum and euphyllite. In *Tenn.*, at Ducktown copper mines.

Neither zoisite nor epidote has yet been found among furnace or laboratory products.

On cryst., B. & M., p. 306; Descl., Min., i. 238. The crystal figured above by the author (and from the cabinet of Prof. Brush) is ½ in. long, but was attached by one side to a large imperfect crystal, and hence its planes were irregularly developed. The left 1-ī and 2-4 were minute and somewhat rounded. The angle *I* ∧ *i*-ī by Descloizeaux's measurement, is 121° 40′, as given above: Descloizeaux obtained also for *i*-ī ∧ *i*-2=162° 20′, ½-ī ∧ ½-ī, top, =120° nearly; for *i*-ī ∧ *i*-2=107° 13′, whence *i*-2 ∧ *i*-2=145° 34′, and Miller found 107° 12′, whence 145° 36′.

Zoisite is closely isomorphous with epidote. If the figure 266 under epidote (p. 28) is placed with the longer planes vertical, it then represents very nearly the form of zoisite; the angle of this prism *i*-ī ∧ 1-ī is 115° 24′, and −1 ∧ −1=109° 35′; and correspondingly, the prismatic angle of zoisite is 116° 40′, and the brachydome 1-ī has the summit angle 109° 20′. The position given the crystals of epidote by Haüy has therefore a crystallogenic interest, and the name he applied to the species peculiar significance.

280A. JADEITE. Nephrite or Jade pt. Jadeite *Damour*, C. R., lxi. 360.

Massive, with traces of a foliated columnar structure on a surface of fracture.

H.=6·5—7. G.=3·33—3·35, fr. China, Damour; 3·32, fr. Yunnan, China, Brush; 3·32, fr. ornaments in ancient Swiss lake-dwellings, Fellenberg. Lustre subvitreous, pearly on surfaces of cleavage. Color apple-green to nearly emerald-green, bluish-green, leek-green, greenish-white, and nearly white. Streak uncolored. Translucent to subtranslucent. Fracture splintery.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$=1 : 2 : 6, with the protoxyds mainly soda; $(\frac{1}{3}(\frac{2}{3}\dot{\mathrm{Na}}+\frac{1}{3}\dot{\mathrm{R}})^3+\frac{2}{3}\bar{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+3\ddot{\mathrm{Si}}$; or, with half the excess of silica basic;=, if $\dot{\mathrm{R}}=\dot{\mathrm{Ca}}$, Silica 58·4, alumina 22·2, [illegible] 6·0, soda 13·4=100. It has the O. ratio and constituents of dipyre, while like zoisite i:

its very high specific gravity, as remarked by T. S. Hunt, who refers the species to the epidote group (C. R., June, 1863), and gives the species the same position in that group as dipyre in the scapolite group.

Analyses: 1, Damour (l. c.); 2, Fellenberg (Nat. Ges. Bern, 1865, 112):

	$\ddot{\text{Si}}$	$\bar{\ddot{\text{A}}}\text{l}$	$\dot{\text{F}}\text{e}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{N}}\text{a}$	$\dot{\text{K}}$	$\dot{\text{H}}$
1. China	59·17	22·58	1·56	1·15	2·68	12·93	*tr.*	——=100·07 Damour.
2. Swiss Lake-hab.	58·89	22·40	1·66	1·28	3·12	12·86	0·49	0·20, $\dot{\text{Z}}\text{n}$ 0·73=101·03 Fell

In an imperfect analysis of a specimen from the province of Yunnan, China, obtained by R. Pumpelly, Wm. Cook found (priv. contrib.) $\ddot{\text{Si}}$ 59·35, $\bar{\ddot{\text{A}}}\text{l}$ 24·07, $\dot{\text{M}}\text{g}$ *tr.*, $\dot{\text{C}}\text{a}$ 0·77, $\dot{\text{N}}\text{a}$ 13·01, $\dot{\text{K}}$ 0·18, $\dot{\text{H}}$ 0·30=97·60. The analysis shows that Mr. Pumpelly rightly indentifies this stone, the Feitsui of the Chinese, with jadeite (Geol. China, etc., 117, 118, 1866, Smithson. Contrib., No. 202)

Pyr., etc.—B.B. fuses readily to a transparent blebby glass. Not attacked by acids after fusion, and thus differing from saussurite.

Obs.—Jadeite is one of the kinds of pale green stones used in China for making ornaments, and passing under the general name of jade or nephrite. Mr. Pumpelly remarks that the *feitsui* is perhaps the most prized of all stones among the Chinese. He also observes that the *chalchihuitl* of the ancient Mexicans, of which he had seen many specimens, is probably the same mineral. But W. P. Blake identifies this name with the turquois from the vicinity of Santa Fe (Am. J. Sci., II. xxv. 227).

281. PARTSCHINITE. Partschin *Haid.*, Ber., iii. 440, 1847, Ber. Ak. Wien, xii. 480.

Monoclinic. $I \wedge I=91° \ 52'$, $C=52° \ 16'$, $O \wedge i\text{-}\grave{i}=127° \ 44'$, $O \wedge 1\text{-}\grave{i}=148°$, $O \wedge I=116° \ 5'$, $1\text{-}\grave{i} \wedge 1\text{-}\grave{i}$, ov. O,=116°, $O \wedge \frac{1}{2}=126° \ 51'$.

H.=6·5—7. G.=4·006, v. Hauer. Lustre a little greasy, feeble. Color yellowish, reddish. Subtranslucent. Fracture subconchoidal.

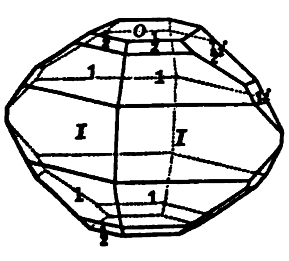
Comp.—O. ratio for $\dot{\text{R}}$, $\ddot{\text{R}}$, $\ddot{\text{Si}}$, 1 : 1 : 2, as in garnet, and near spessartine. Von Hauer obtained (l. c., ½) $\ddot{\text{Si}}$ 35·63, $\bar{\ddot{\text{A}}}\text{l}$ 18·99, $\dot{\text{F}}\text{e}$ 14·17, $\dot{\text{M}}\text{n}$ 29·23, $\dot{\text{C}}\text{a}$ 2·77, $\dot{\text{H}}$ 0·38.

Obs.—In very small dull crystals and rounded fragments, in the auriferous sands of Ohlapian, Transylvania.

282. GADOLINITE. Schwarzer Zeolith (fr. Ytterby) *Geyer*, Crell's Ann., 1788. Ytterbit (Silicate of Alumina, Ox. Iron, and a new earth) *Gadolin*, Ak. H. Stockh., 1794; *Ekeberg*, ib., 1797 (naming the earth YTTRIA). Gadolinit *Klapr.* (Ak. Berlin, 1800), Beitr., iii. 52, 1802.

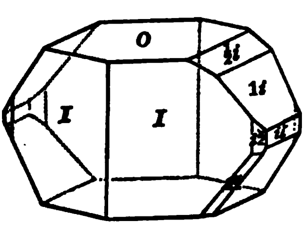
Orthorhombic. $I \wedge I=116°$, $O \wedge 1\text{-}\bar{i}=114° \ 24'$; $a : b : c=2{\cdot}2054 : 1 : 1{\cdot}6003$, Nordenskiöld, or near zoisite, if a be made $\frac{1}{2}a$. Observed planes:

273.



Ytterby.

274.



Ytterby.

O; vertical, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\frac{3}{2}$; brachydomes, $\frac{1}{2}\text{-}\breve{i}$, $1\text{-}\breve{i}$, $2\text{-}\breve{i}$; macrodomes, $\frac{1}{4}\text{-}\bar{i}$, $\frac{1}{2}\text{-}\bar{i}$; octahedral, 1, $\frac{1}{2}$, 1-2, $2\text{-}\frac{3}{2}$, $\frac{3}{2}\text{-}\breve{\frac{3}{2}}$, $2\text{-}\breve{\frac{4}{3}}$. Cleavage none.

$O \wedge 1\text{-}\breve{\imath}=125° 58'$ $O \wedge 1=111° 2'$ $I \wedge i\text{-}\breve{\imath}=122°$
$O \wedge 2\text{-}\breve{\imath}=109\ 57$ $2\text{-}\breve{\imath} \wedge 2\text{-}\breve{\imath}$, top, $=39\ 54$ $I \wedge i\text{-}\breve{2}=160\ 40'$
$O \wedge \frac{1}{2}\text{-}\breve{\imath}=146\ 26$ $\frac{1}{2}\text{-}\breve{\imath} \wedge \frac{1}{2}\text{-}\breve{\imath}$, top, $=110\ 52$ $I \wedge 1=158\ 58$

H.=6·5—7. G.=4—4·5; of Ytterby 4·097—4·226, but after heating 4·286—4·456, H. Rose; 4·35, from Hitteröe, Scheerer. Lustre vitreous. Color black, greenish-black; in thin splinters nearly transparent, and grass-green to olive-green. Streak greenish-gray. Double refraction in Hitteröe crystals, sometimes distinct, with optical axes very divergent, in others often wanting. In the mass subtranslucent—opaque. Fracture conchoidal.

Comp., Var.—Gadolinite varies widely in its crystals, and physical and chemical characters, even in specimens from the same locality, and much more so in those of different. The crystals are usually rough and irregular, and sometimes oblique in different directions. Haüy (Min., 1822), Phillips (Min., 1823), Levy (Min. Heuland, ii. 46), Kupffer, Scheerer (Gæa Norvegica, 313), and Waage (Forh. Selsk. Christiania, 1864, and Jahrb. Min, 1867, 696) have made it *monoclinic*; and Brooke and Miller (Min., 322, using the same cryst. examined by Phullips), Scheerer (Jahrb. Min., 1861, 134), A. E. Nordenskiöld (Œfv. Ak. Stockh., 1859, 287), and Maskelyne and v. Lang (Phil. Mag., IV. xxviii. 145) have made it orthorhombic:

	Phillips, fr. Kararfvet.	Levy.	Scheerer, fr. Hitteröe.	Waage, fr. Hitteröe.

$O \wedge \frac{1}{2}\text{-}\breve{\imath}$	—	124 34	125 58	———
$I \wedge I$	119 30′	116	116 30	———

Maskelyne and v. Lang state that the crystals from Ytterby are sometimes oblique in the direction of one diagonal, and sometimes in that of the other; they adopt Nordenskiöld's calculated results. Waage, who makes the form monoclinic, enumerates the planes O, I, $i\text{-}i$, $i\text{-}\grave{2}$, 1, −1, $\frac{1}{2}$, $-\frac{1}{2}$, 1-2, $\frac{1}{2}\text{-}i$, $1\text{-}i$. His measurements were made with the reflective goniometer, and agree well with his calculated results; which, in addition to the above, are, $O \wedge I=89° 31'$, $O \wedge 1=111° 29$, $O \wedge -1=112° 21'$, $O \wedge \frac{1}{2}\text{-}i=136° 7'$, $1 \wedge -1=136° 10'$, $I \wedge 1=158° 8'$, $I \wedge -1=158° 2'$. Waage points out a relation in angles to epidote, observing that the prismatic angle, 116°, which is nearly that of zoisite, corresponds to $\frac{3}{2}\text{-}i \wedge \frac{3}{2}\text{-}i$ in epidote (=115° 32′).

The Ytterby crystals examined by v. Lang were partly altered. Descloizeaux found crystals from this locality part a mixture of double and singly refracting material, and part without any action on polarized light. Amid the diversity of results it is impossible to decide which is the correct form.

The variations in composition are also considerable. The Ytterby, Finbo, and Broddbo gadolinite afford approximately the formula $\dot{R}^3\ddot{S}i$; that of Hitteröe, $\dot{R}^3\ddot{S}i^2$, the O. ratio between the bases and silica being approximately 4 : 3, as in euclase. That analyzed by Bahr and Bunsen has the O. ratio 3 : 2.

Analyses: 1, 2, Berzelius (Afhandl., iv. 148, 389); 3–6, Berlin (Dissert. Gadol. Upsal., 1844, and Œfv. Ak. Stockh., 1845, 86); 7, Berzelius (l. c.); 8, Richardson (Thom. Min., i. 410); 9, 10, Scheerer (De Foss. Allauit, etc., Berolini, 1840, and Pogg., lvi. 479); 11, König (Ann. Ch. Pharm. cxxxvii. 83):

[a] With oxyd of Lanthanum. [b] $\dot{\mathrm{E}}$ 2·98, $\dot{\mathrm{Ce}}$ 2·86, $\dot{\mathrm{D}}$ 8·33, $\dot{\mathrm{La}}$ 3·21.

Of Berlin's analyses, the first two were of the glassy gadolinite.

The oxygen ratio between the bases and silica in anal. 1 is 1 : 1·02; in 2, 1 : 1; in 3, 1 : 0·94; in 4, 1 : 0·94; in 5, 1 : 0·85; in 6, 1 : 0·92; in 9, 10, 1 : 0·72. Connell obtained, for a specimen labelled Fahlun, $\dddot{\mathrm{Si}}$ 27·00, $\overline{\mathrm{Be}}$ 6·00, $\overline{\mathrm{Fe}}$ 14·50, $\dot{\mathrm{Y}}$ 36·50, $\overline{\mathrm{Ce}}$ 14·33, $\dot{\mathrm{Ca}}$ 0·50=98·83 (Edinb. N. Phil. J., 1836, June); which, taking the iron as protoxyd, gives the oxygen ratio for $\dot{\mathrm{R}}+\overline{\mathrm{Be}}$, $\dddot{\mathrm{Si}}$, 1 : 0·92.

Pyr., etc.—The glassy variety is unchanged in the closed tube, but if heated B.B. the assay gives for a moment a bright light, as if it had taken fire, swells up, cracks open, and becomes grayish-green in color without fusing. The splintery variety swells into cauliflower-like ramifications and becomes white, rarely glowing. With borax gives an iron reaction. Only slightly acted upon by salt of phosphorus. Decomposed by muriatic acid with gelatinization.

Obs.—Gadolinite occurs principally in the quarries of Kararfvet, Broddbo, and Finbo, near Fahlun in Sweden; also at Ytterby, near Stockholm; at each place indistinctly crystallized, and in rounded masses, which are often encircled with a yellow crust, and imbedded in coarse-grained granite. At Kararfvet crystals have been obtained 4 in. long. It has also been met with at Disko in Greenland; in trap near Galway, Ireland; imbedded in granite in Ceylon; at Brevig and Hitteröe in the southern part of Norway, crystals sometimes 4 in. across and twins at this last locality.

Named after the Russian chemist, Prof. Gadolin.

283. MOSANDRITE. *Erdmann*, Jahresb., xxi. 178, 1841.

Orthorhombic? $I \wedge I$ about 117° 16′, $I \wedge i\text{-}\breve{i}$=121° 10′ to 120° 40′, $i\text{-}\breve{i} \wedge i\text{-}\breve{2}$=139° 40′ to 141°, $I \wedge i\text{-}\breve{2}$=160° to 161°, $i\text{-}\breve{i} \wedge i\text{-}\breve{3}$=151° 20, Descl. Cleavage: $i\text{-}\breve{i}$ perfect. Crystals long prisms, usually flattened parallel to $i\text{-}\breve{i}$, and longitudinally striated. Also massive and fibrous.

H.=4. G.=2·93—3·03. Lustre of cleavage-face between vitreous and greasy, of other surfaces resinous. Color reddish-brown, but altering to dull greenish or yellowish-brown. Streak-powder pale yellow or grayish-brown. Thin splinters translucent, bright red by transmitted light. Double refraction feeble; optic-axial plane vertical, and normal to $i\text{-}\breve{i}$; acute bisectrix negative, and apparently at right angles to $i\text{-}\breve{i}$, Descl.

Comp.—Analysis by Berlin (Pogg., 156, 1853):

$\dddot{\mathrm{Si}}$	$\ddot{\mathrm{Ti}}$	$\overline{\mathrm{Ce}}$, $\dddot{\overline{\mathrm{La}}}$, $\dddot{\overline{\mathrm{D}}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
29·93	9·90	26·56	1·83	0·75	19·07	2·87	0·52	8·90=100·33

There is some $\overline{\mathrm{Mn}}$ with the $\overline{\mathrm{Fe}}$. Reckoning the $\ddot{\mathrm{Ti}}$ with the bases, as forming part of a sesquioxyd, as in sphene and keilhauite, the oxygen ratio of the protoxyds, sesquioxyds, and silica, is nearly 1 : 2 : 3, or of bases and silica 1 : 1 (precisely 16·57 : 15·86), affording the formula $(\frac{1}{3}\dot{\mathrm{R}}^3+\frac{2}{3}\overline{\mathrm{R}})^2\dddot{\mathrm{Si}}^3+1\frac{1}{2}\dot{\mathrm{H}}$. This, excluding the water, is the formula of epidote, to which the species may be related.

Pyr., etc.—In the closed tube gives water. B.B. fuses with intumescence at 3 to a brown glass. With salt of phosphorus in R.F. gives a violet bead (titanic acid) and with borax in O.F gives an amethystine bead (manganese). Decomposed by muriatic acid, with separation of silica and formation of a dark red solution, which, on heating, gives off chlorine and becomes yellow.

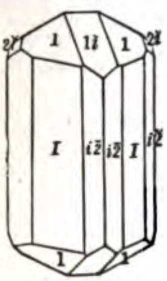
Obs.—Occurs at Brevig, in syenite, with leucophanite, eucolite, elæolite, ægirite, black mica on the island of Lammanskäret near Brevig, Norway. Readily undergoes alteration.

Descloizeaux observes that mosandrite may be regarded approximately as isomorphous with zoisite, in which $i\text{-}\bar{i} \wedge i\text{-}\breve{3}=151° 48'$, $I \wedge I=116° 16'$ (Min., i. 533).

284. ILVAITE. Yenite (fr. Elba) *Lelièvre*, J. d. M., xxi. 65, 1807. Ilvait *Steffens*, Orykt., i. 356, 1811. Lievrit *Wern.*, Hoffm. Min., ii. a, 376, 1812. Wehrlit *v. Kob.*, Grundz., 313, 1838.

Orthorhombic. $I \wedge I=112° 38'$, $O \wedge 1\text{-}\bar{i}=146° 24'$; $\breve{a} : \bar{b} : c=0{\cdot}66608 : 1 : 1{\cdot}5004$. Observed planes: O; vertical, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\breve{2}$, $i\text{-}\breve{\tfrac{4}{3}}$, $i\text{-}\bar{2}$, $i\text{-}\bar{3}$, $i\text{-}\bar{4}$, $i\text{-}\bar{\tfrac{4}{3}}$?; domes, $1\text{-}\bar{i}$, $3\text{-}\bar{i}$, $\tfrac{1}{2}\text{-}\breve{i}$, $2\text{-}\breve{i}$; pyramids, 1; in zone $i\text{-}\bar{i}$: 1, $2\text{-}\bar{2}$, $3\text{-}\bar{3}$, $4\text{-}\bar{4}$; in zone $i\text{-}\breve{i}$: 1, $2\text{-}\breve{2}$, $3\text{-}\breve{3}$.

275



$O \wedge 3\text{-}\bar{i}=116° 39'$
$O \wedge 2\text{-}\breve{i}=138\ 29$
$O \wedge 1=141\ 24$
$O \wedge \tfrac{1}{2}\text{-}\breve{i}=167\ 31$
$O \wedge 2\text{-}\bar{i}=138\ 29$
$1 \wedge 1$, mac.,$=139\ 32$

$1 \wedge 1$, brach.,$=117° 27'$
$i\text{-}\breve{2} \wedge i\text{-}\breve{2}=143\ 8$
$1\text{-}\bar{i} \wedge 1\text{-}\bar{i}=112\ 49$
$i\text{-}\breve{2} \wedge i\text{-}\breve{2}$, brach.,$=106\ 15$
$I \wedge i\text{-}\breve{2}=160\ 34$
$I \wedge i\text{-}\bar{2}=164\ 45$

Lateral faces usually striated longitudinally. Cleavage: parallel to the longer diagonal, indistinct. Also columnar or compact massive.

H.$=5{\cdot}5$–6. G.$=3{\cdot}7$–$4{\cdot}2$; 3·994, fr. Elba, Haidinger; 3·9796, ib., Stromeyer; 3·825–4·061, ib., Lelièvre; 3·711, fr. Nassau, Tobler. Lustre submetallic. Color iron-black, or dark grayish-black. Streak black, inclining to green or brown. Opaque. Fracture uneven. Brittle.

Comp.—O. ratio, from Tobler's anal. (No. 7), for $\dot{R}$, $\bar{R}$, $\ddot{Si}=3 : 2 : 5$, whence $(\tfrac{3}{5}\dot{R}^3+\tfrac{2}{5}\bar{R})^2\ddot{Si}^2$ =Silica 32·8, sesquioxyd of iron 23·4, prot. id. 31·5, lime 12·3=100; and, as the specimens were partly in crystals (having the planes $i\text{-}\breve{2}$, $1\text{-}\bar{i}$, I, 1), this may be the normal composition of the species. This variety is of low specific gravity, and contains much manganese.

The other analyses show a deficiency of silica for a unisilicate. In Rammelsberg's (No. 3) the O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}=11{\cdot}08 : 6{\cdot}76 : 15{\cdot}90 : 1{\cdot}42$; or for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}=9 : 8 : 0{\cdot}75$. In anal. 2, the last ratio is $7 : 6 : 0{\cdot}4$, and in No. 5, $6 : 5 : 0$.

Städeler found water a constant ingredient, and, as it was not expelled below ignition, regards it as basic. His closely-agreeing analyses give for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}$ the O. ratio $9 : 8 : 1$, and for $\dot{Ca}$, $\dot{Fe}$, $\bar{Fe}$, $2 : 4 : 1$. If $\dot{H}$ be basic, the O. ratio of bases and silica is $5 : 4$, which is expressed in the formula $(\dot{H}^3, \dot{R}^3, \bar{R})^4\ddot{Si}^6$.

But in view of the variation in ratio in the analyses of the Elba mineral, and its opacity, we may reasonably infer that impurities are present (as staurolite exemplifies, p. 388), and that these impurities are mainly hydrated oxyd of iron, of the species göthite, which mineral loses its water at a high temperature. Allowing for this admixture, all ilvaite may come under the general formula $(\dot{R}^3, \bar{R})^2\ddot{Si}^3+m\bar{Fe}\dot{H}$; with the O. ratio for bases and silica $7 : 6$, m would equal $\tfrac{1}{3}$.

Analyses: 1, Stromeyer (Unters., 372); 2, same with v. Kobell's estimation of the iron (Schw. J., lxii. 166); 3, Rammelsberg (Pogg., l. 157, 340, Min. Ch., 740); 4, 5, Wackernagel and Franke (Min. Ch., ib.); 6, Städeler (J. pr. Ch., xcix. 70); 7, Tobler (Ann. Ch. Pharm., xcix. 122):

Werner placed lievrite in his system next to epidote.

Pyr., etc.—B.B. fuses quietly at 2·5 to a black magnetic bead. With the fluxes reacts for iron Some varieties give also a reaction for manganese. Gelatinizes with muriatic acid.

Obs.—First found on the Rio la Marina, and at Cape Calamita, on Elba, by M. Lelièvre, in 1802, where it occurs in large solitary crystals, and aggregated crystallizations in dolomite with pyroxene, etc. Also found at Fossum in Norway; in Siberia; near Andreasberg in the Harz; at the mine of Temperino in Tuscany, granular, in limestone with actinolite; near Predazzo, Tyrol, in granite; at Schneeberg in Saxony; at Skeen in Norway; at Hebrun in Nassau; at Kangerdluarsuk in Greenland.

Reported as formerly found at Cumberland, R. I., in slender black or brownish-black crystals, traversing quartz along with magnetite and hornblende; also at Milk Row quarry, Somerville, Mass.

On cryst., Descloizeaux, Ann. d. M., V. viii. 402, and his Mineralogie, 1862, from whom the above angles are taken; his calculations were made from 1 ∧ 1 and 1-ī ∧ 1-ī. The observed angle *I* ∧ *I* was about 111°. Also Hessenberg, Min. Not., No. III. 1.

Named *Ilvaite* from the Latin name of the island (Elba) on which it was found; *Lievrite* after its discoverer; *Yenite* (should have been Jenite) in commemoration of the battle of Jena, in 1806. The Germans, and later the French, have rightly rejected the name *yenite*, on the ground that commemorations of political hostility or triumph are oppôsed to the spirit of science. Descloizeaux adopts *Ilvaite*.

A boulder from near Bytown, Canada, analyzed by T. S. Hunt, gave (Logan's Rep., 1853, 1863) $\ddot{\text{S}}\text{i}$ 27·80—28·20, $\bar{\ddot{\text{F}}}\text{e}$ 10·80, $\dot{\text{F}}\text{e}$ 56·52, $\dot{\text{M}}\text{g}$ 2·59, $\dot{\text{C}}\text{a}$ 0·64, ign. 1·20=99·55; and is referred by him to lievrite. It is black, submetallic, and magnetic, with two oblique cleavages; H.=5·5; G.= 4·15—4·16; and in powder it gelatinizes with acids. The composition is essentially that of *fayalite*: and the substance, although stated to contain some black mica and red granular garnet, has been supposed to be a furnace slag.

Wehrlite is probably lievrite, as suggested by Zipser. It is massive granular. H.=6—6·5. G.=3·90. Analysis by Wehrle, $\ddot{\text{S}}\text{i}$ 34·60, $\bar{\ddot{\text{F}}}\text{e}$ 42·38, $\bar{\ddot{\text{M}}}\text{n}$ 0·28, $\bar{\ddot{\text{A}}}\text{l}$ 0·12, $\dot{\text{F}}\text{e}$ 15·78, $\dot{\text{C}}\text{a}$ 5·84, $\dot{\text{H}}$ 1·00 =100. B.B. fuses with difficulty on the edges. Imperfectly soluble in muriatic acid. From Szurraskó, Hungary.

If *i*-$\frac{3}{2}$ be taken as *I* in lievrite, the form becomes very nearly tetragonal, affording *I* ∧ *I* within half a minute of 90°, *O* ∧ 1-ī=146° 24′, 1-ī ∧ 1-ī=112° 49′.

5. Treseburg	43·74	—	15·66	11·94	1·37	18·90	1·77	—, $\dddot{B}$, $\dot{K}$ and loss 6·62 Ramm.
6 Ural	43·72	—	16·92	10·21	1·16	19·97	2·21	—, $\dddot{B}$, $\dot{K}$ and loss 5·81 Ramm.

Rammelsberg states that, in the last two analyses, 4·5 of the last entry in each is not too large an estimate for the boric acid.

Pyr., etc.—B.B. fuses readily with intumescence, imparts a pale green color to the O.F., and fuses at 2 to a dark green to black glass; with borax in O.F. gives an amethystine bead (manganese), which in R.F. becomes yellow (iron). Fused with a mixture of bisulphate of potash and fluor on the platinum loop colors the flame green (boric acid). Not decomposed by acids, but when previously ignited, gelatinizes with muriatic acid.

Obs.—Axinite occurs in implanted glassy clove-brown crystals, at St. Cristophe, near Bourg d'Oisans in Dauphiny, with albite, prehnite, and quartz; at Santa Maria, Switzerland; at the silver mines of Kongsberg, in smaller crystals; with hornblende or magnetic iron in Normark in Sweden; in Cornwall, of a dark color, at the Botallack mine, where it also occurs massive, forming a peculiar kind of rock with garnet and tourmaline; at Trewellard, at Carn Silver near Lamorran creek, and at Boscawen Cliffs in St. Burien; in Devonshire, at Brent Tor, 4 m. north of Tavistock; at Thum near Ehrenfriedersdorf in Saxony. It occurs with gray cobalt near Coquimbo, Chili, at the mine La Buitre; at Phipsburg, Maine, with yellow garnet and idocrase; at Wales, Maine; at Cold Spring, N. Y.

For recent articles on cryst., Descl. Min., i. 516; Hessenberg, Min. Not., No. V. p. 27, f. 23; v. Rath, Pogg., cxxviii. 20, 227. Figs. 2, 3, and the above list of planes and angles, are from v. Rath. Fig. 1 is from Rose and Riess on the Pyroelectricity of Axinite, Schrift. Ak. Berlin, lix. 375

Axinite admits of a high polish, but is deficient in delicacy of color.

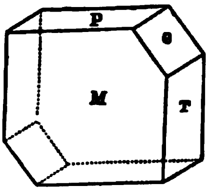
Well named from ἀξίνη, *an axe*, in allusion to the form of the crystals. The name *yanolite* is of earlier date; but it means *violet-stone*, and violet is not a characteristic color of the mineral.

Alt.—Crystals altered to chlorite occur on Dartmoor in Devonshire, England.

286. DANBURITE. Danburite *Shepard*, Am. J. Sci., xxxv. 137, 1839.

Triclinic. Approximate angles, P ∧ M=110° and 70°, M ∧ T=54°, and 126°, P ∧ T=93° nearly, P ∧ e=135°. Cleavage: distinct, parallel to M and P, less so parallel to T. Crystals imbedded, and often an inch broad. Also disseminated massive, without regular form.

279



H.=7. G.=2·95, Silliman, Jr.; 2·957, 2·958, Brush. Color pale yellow, whitish. Lustre vitreous, but usually rather weak. Translucent to subtranslucent. Very brittle.

Comp.—*O* ratio for $\dot{R}$, $\overline{\overline{B}}$, $\ddot{S}i$=1 : 3 : 4; $\dot{C}a^3\,\ddot{S}i+\overline{\overline{B}}^3\,\ddot{S}i^3=(\frac{1}{4}\,\dot{C}a^3+\frac{3}{4}\,\overline{\overline{B}})^2\,\ddot{S}i^3$=Silica 48·9, boric acid 28·4, lime 22·7=100. Analyses: 1, 2, Smith and Brush (Am. J. Sci., II. xvi. 365):

	$\ddot{S}i$	$\overline{\overline{B}}$	$\overline{\overline{A}}l\ \overline{\overline{F}}e$	$\dot{M}n$	$\dot{C}a$	$\dot{M}g$	ign.
1.	48·10	27·73	0·30	0·56	22·41	0·40	0·50=100.
2.	48·20	27·15	1·02		22·33	*undet.*	0·50=99·20.

Erni was the first to detect the boric acid, but as he admits (Erni's Mineralogy simplified, p. 147), his analysis was incorrect—the mineral not containing the 10 p. c. of alkalies announced by him, as directly proved by Smith and Brush. Shepard stated (l. c.) that the mineral had 8 p. c. of water without boric acid; and yet it is certain that the mineral was the same that was investigated by Smith and Brush.

Pyr., etc.—Yields no water in the closed tube. B.B. fuses at 3·5 to a colorless glass, and imparts a green color to the O.F.; this is heightened by moistening the assay with sulphuric acid before heating. Not decomposed by muriatic acid, but sufficiently attacked for the solution to give the reaction of boric acid with turmeric paper. When previously ignited gelatinizes with muriatic acid.

Obs.—Occurs with orthoclase and oligoclase in dolomite at Danbury, Connecticut. It has some resemblance to chondrodite in color, lustre, and brittleness, but is distinctly cleavable, although the planes of cleavage are often irregular; it may be readily recognized by its pyrognostic characters.

287. IOLITE. Spanischer Lazulith *v. Schlottheim*, Hoff Mag. Min., i. 169, 1801. Iolith (fr. Spain) *Wern.*; *Karst.* (with descr.), Tab., 46, 92, 1808. Orthorhombic. In stout prisms often hexagonal. $I \wedge I$=119° 10′ and 60° 50′, $O \wedge 1\text{-}\bar{i}$=150° 49′. Observed planes: *O*; vertical, I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\breve{3}$; domes, $\frac{1}{2}\text{-}\breve{i}$, $1\text{-}\breve{i}$, $2\text{-}\breve{i}$; pyramids, $\frac{1}{3}$, $\frac{1}{2}$, 1, $3\text{-}\breve{3}$. $O \wedge 1$=132° 12′, $O \wedge \frac{1}{2}$=150° 7′, $I \wedge i\text{-}\breve{3}$=150°, $i\text{-}\breve{i} \wedge i\text{-}\breve{3}$ =150° 25′, $i\text{-}\breve{3} \wedge i\text{-}\breve{3}$=120° 50′. Cleavage: $i\text{-}\breve{i}$ distinct; $i\text{-}\bar{i}$ and *O* indistinct. Crystals often transversely divided or foliated parallel with *O*. Twins: composition-face *I*. Also massive, compact.

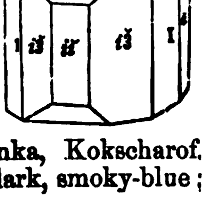
280



H.=7—7·5. G.=2·56—2·67; 2·5969, Greenland, Stromeyer; 2·65—2·6643, Haddam, Thomson; Ostgothland 2·64, Südermanland 2·61, Schütz; 2·605, Mursinka, Kokscharof. Lustre vitreous. Color various shades of blue, light or dark, smoky-blue;

pleochroic, being often deep blue along the vertical axis, and brownish yellow or yellowish-gray perpendicular to it. Streak uncolored. Transparent—translucent. Fracture subconchoidal. Double refraction feeble; bisectrix negative, normal to *O*.

Comp.—O. ratio for bases and silica 4 : 5 or 1 : 1¼. The state of oxydation of the iron is still unascertained, and hence there is uncertainty as to the proportion between the protoxyds and sesquioxyds. The ratio usually deduced for $\dot{R}$, $\ddot{R}$, $\dddot{S}i$ is 1 : 3 : 5. The formula $2\,\dot{R}\,\dddot{S}i+\ddot{R}^{2}\dddot{S}^{3}$, which corresponds to this ratio, =, if $\dot{M}g$: $\dot{F}e$=2 : 1, Silica 49·4, alumina 33·9, magnesia 8·8, protoxyd of iron, 7·9=100.

Analyses: 1–3, Stromeyer (Unters., 329, 431); 4, 5, Schütz (Pogg., liv. 565); 6, Scheerer (Pogg., lxviii. 319); 7, Hermann (Kokscb. Min. Pyr., etc.—B.B. loses transparency and fuses at 5—5·5. Only partially decomposed by acids. Decomposed on fusion with alkaline carbonates.

Obs.—Iolite occurs in granite, gneiss, hornblendic, chlorite and talcose schist, and allied rocks, with quartz, orthoclase or albite, tourmaline, hornblende, andalusite, and sometimes beryl. Also rarely in volcanic rocks.

At Bodenmais, Bavaria, it is met with in granite, in crystals, along with pyrrhotine, blende, chalcopyrite; the variety is the *peliom* of Werner, named from πέλιος in allusion to its smoky blue color. It occurs in quartz at Ujordlersoak in Greenland; in granite at Cape de Gata, in Spain; at Krageröe in Norway; Orijerfvi, in Finland (*steinheilite*); Tunaberg, in Sweden; Finspaong in Ostgothland; Brunhult in Sudermanland; Fahlun (*hard fahlunite*); Lake Laach, with sanidin; at Campiglia Maritima, Tuscany, in a trachytic rock, containing also mica, quartz, and sanidin. Ceylon affords a transparent variety, in small rolled masses of an intense blue color, the *sapphir d'eau* of jewellers.

At Haddam, Conn., associated with tourmaline in a granitic vein in gneiss; sparingly at the chrysoberyl locality, in an altered or fahlunite condition; abundant in quartz with garnet and yellowish-green feldspar, near the Norwich and Worcester Railway, between the Shetucket and Quinnebaug, where the gneiss has been quarried for the road. At Brimfield, Mass., on the road leading to Warren, near Sam Patrick's with adularia, in gneiss; also good at Richmond, N. H., in talcose rock, along with anthophyllite.

Iolite is occasionally employed as an ornamental stone, and when cut exhibits different colors in different directions.

Named *Iolite* from ἴον, *violet*, and λίθος, *stone*; *Dichroite*, from its dichroism; *Cordierite*, after Cordier, the geologist, who first studied the crystal of the species; *Steinheilite* by Gadolin after Mr. Steinheil. Lucas and Haüy, who adopt *cordierite*, rejected the earlier names *iolite* and *dichroite* because the former is not always applicable, and the latter is equally applicable to various other stones. *Epidote*, *pyroxene*, and a multitude of other names, if judged by the same code, would be found to have no better claim to recognition.

Alt.—The alteration of iolite takes place so readily by ordinary exposure, that the mineral is most commonly found in an altered state, or enclosed in the altered iolite. This change may be a simple hydration (*fahlunite*, etc.); or a removal of part of the protoxyd bases by carbonic acid; or the introduction of oxyd of iron; or of alkalies, forming pinite and mica. The first step in the change consists in a division of the prisms of iolite into plates parallel to the base, and a pearly foliation of the surfaces of these plates; with a change of color to grayish-green and greenish-gray, and sometimes brownish-gray. As the alteration proceeds, the foliation becomes more com plete; afterward it may be lost. The mineral in this altered condition has many names: as *hydrous iolite*, *pinite*, *cataspilite*, *fahlunite*, *bonsdorffite*, *esmarkite*, *chlorophyllite*, *gigantolite*, *praseolite*, *aspasiolite*. Pinite, as far as it is altered iolite, includes properly the alkaline kinds. Fahlunite and the following, excepting the last, correspond to iolite + aq. In most cases if the water of the altered iolite be included with the bases, the oxygen ratio between the bases and silica becomes 1 : 1; it seems, therefore, quite probable that the strong tendency of iolite to take up water is owing to the fact that its silica (whose amount of oxygen exceeds that of the bases by one-fourth) is not saturated with bases. Regarding the water of the altered mineral as basic, *esmarkite*, *chlorophyllite*, *gigantolite*, and *praseolite* will have the formula $(\dot{R}^3, \ddot{R})\, \ddot{Si}$; and *fahlunite* and *bonsdorffite*, containing twice as much water as the preceding, would have the formula $(\dot{R}^3, \rlap{-}R)\, \ddot{Si} + \dot{H}$. If 1 : 3 : 5 : 0 be the oxygen ratio for $\dot{R}$, $\rlap{-}R$, $\ddot{Si}$, $\dot{H}$ in iolite, 1 : 3 : 5 : 1 will be the ratio for *esmarkite*, etc., and 1 : 3 : 5 : 2, for *fahlunite*, etc. *Weissite*, *iberite*, *huronite* are names of other minerals supposed to be altered iolite.

For the distinguishing characters and analyses of the different kinds of altered iolite, see PINITE, FAHLUNITE, and CATASPILITE, under HYDROUS SILICATES.

MICA GROUP.

The minerals of the Mica group are alike in having (1) the prismatic angle 120°; (2) eminently perfect basal cleavage, affording readily very thin, tough, laminæ; (3) potash almost invariably among the protoxyd bases and alumina among the sesquioxyd; (4) the crystallization either hexagonal or orthorhombic, and therefore the optic axis, or optic-axial plane, at right angles to the cleavage surface.

Soda is sparingly present in some micas, and is characteristic of the hydrous species paragonite (p.437). Lithia, rubidia, and cæsia occur in lepidolite. Fluorine is often present, probably replacing oxygen. Titanium is found sparingly in several kinds, and is a prominent ingredient of one species, astrophyllite. It is usually regarded as in the state of titanic acid replacing silica; but, for reasons elsewhere given, it is here made basic.

1. *O. ratio for bases and silica* 1 : 1.

288. **PHLOGOPITE.** (1) Contains magnesia, with little or no iron, and much alumina. (2) O. ratio for $\rlap{-}R$, $\ddot{R}$ between 2 : 1 and 5 : 3. (3) Optic-axial angle 3°—20°. (4) Folia tough, and, if not altered, elastic.

289 **BIOTITE.** (1) Contains magnesia and iron, with much alumina. (2) O. ratio for $\dot{R}$, $\rlap{-}R$ about 1 : 1 (rarely 1 : 1½ or 1 : 2.) (3) Optically uniaxial, but often slightly biaxial through irregularity. (4) Folia tough and elastic.

290. **LEPIDOMELANE.** (1) Contains much iron and little magnesia, with much of the alumina replaced by sesquioxyd of iron. (2) O. ratio for $\rlap{-}R$, $\rlap{-}R$ about 1 : 3. (3) Optically like biotite. (4) Folia brittle, hardly at all elastic.

291. **ANNITE**; lepidomelane having the O. ratio for $\rlap{-}R$, $\rlap{-}R$=1 : 2.

292. **ASTROPHYLLITE.** (1) Contains much titanium, zirconium, etc., with little alumina. (2) O. ratio for $\dot{R}$, $\rlap{-}R$ between 2 : 1 and 5 : 3, nearly as in phlogopite. (3) Optic-axial angle *exceeding* 90°. (4) Folia brittle, but slightly elastic.

2. *O. ratio for bases and silica* 1 : 1½ to 1 : 2.

293. **MUSCOVITE.** (1) Contains potash almost alone among protoxyds, with no magnesia, or rarely a little; and alumina as the principal sesquioxyd. (2) O. ratio for $\rlap{-}R$, $\rlap{-}R$ 1 : 6 to 1 : 12, and for $\rlap{-}R+\rlap{-}R$, $\ddot{Si}$ mostly 1 : 1½. (3) Optic-axial angle 40° —75°. (4) Folia tough, elastic, except in some hydrous or altered kinds.

294. **LEPIDOLITE.** (1) Contains lithia, rubidia, and cæsia, with potash as the principal protoxyd, and with alumina as the principal sesquioxyd. (2) O. ratio for $\dot{R}+\rlap{-}R$, $\ddot{Si}$ mostly 1 : 1½. (3) Optic-axial divergence 70°—78°.

295. **CRYOPHYLLITE.** (1) Same constituents as lepidolite. (2) O. ratio for $\dot{R}+\rlap{-}R$, $\ddot{Si}$=1 : 2. (3) Optic-axial angle 50°—60°. (4) Folia tough, elastic.

The species of the Mica group graduate into the hydrous micas of the Margarodite group (p.); and through these they also approach the foliated species of the Talc and Chlorite groups, especially the latter.

The micas were regarded as of one species until 1792, when lepidolite was made distinct. The earlier synonymy therefore may be conveniently given here.

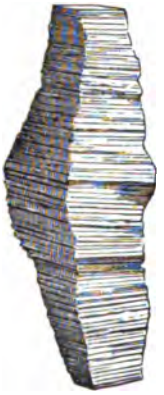
Pliny probably included the mineral mica with the *Lapis specularis* (xxxvi. 45) or *Selenites*; and the shavings or scales of *Lapis specularis* strown over the "Circus Maximus," to produce an agreeable whiteness, were probably those of a soft silvery mica schist. His *Hammochrysos* also (xxxvi 73, named from ἄμμος, *sand*, χρυσός, *gold*) was probably sand from a yellowish mica schist, which abounds by the road-side in many mica-schist regions. Agricola speaks of the deceptive character of this silvery and golden dust, as cited below. This silvery and golden mica in scales is the *Cat-silver* and *Cat-gold* of mediæval Europe. The following is the synonymy of the mineral since the time of Pliny:

Mica, Ammochrysos, colore argento ita simile sit, ut pueros et rerum metallicarum imperitos decipere possit, *Germ.* Glimmer, Katzen-Silber, *Agric.*, Foss., 254, 447, Interpr., 466, 1546. Specularis lapis adulterinus flexilis sexangulorum *Capeller*, Prodr. Cryst., 26, 1723. Mica [Talc not included], Vitrum Muscoviticum, V. Rutheniticum, Skimmer, VAR. alba (Kattsilver), flava (Kattgull), rubra, viridis [Chlorite fr. Sahlberg], nigra, squamosa, radians, fluctuans, hemispherica) *Wall.*, Min., 129, 131, 1747. Mica pt. [rest Talc, Chlorite], Verre de Moscovie, etc., *Fr. Tr.* Wall., i. 241, 1753. Mica, Glimmer, Vitrum Muscoviticum (in plates), Mica squamosa (in scales) *Cronst.*, Min., 88, 1758. Isinglass (in large plates), Glimmer or Mica (in small scales) pt. (rest Talc, Chlorite) *Hill*, Foss., 10, 13, 1771. Glimmer [Chlorite and Talc excluded] *Wern.*, Bergm. J., 37 1789.

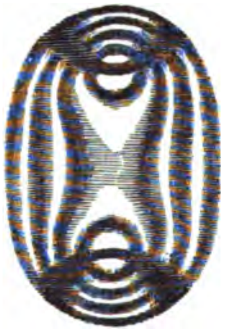
The word *mica* has been said to come from the Latin *mica*, *a crumb* or grain, as it was formerly applied especially to the mineral in scales. It is usually derived, however, from the Latin *micare*, signifying (like the German name *Glimmer*) *to shine*.

288. PHLOGOPITE. Magnesia-Mica pt. Rhombic Mica. Rhombenglimmer pt. Phlogopit (fr. Antwerp, N. Y.) *Breith.*, Handb., 398, 1841.

281



282



Antwerp.

Orthorhombic. $I \wedge I = 120°$, and habit hexagonal. Prisms usually oblong six-sided prisms, more or less tapering, with irregular sides; rarely, when small, with polished lateral planes. Cleavage basal, highly eminent. Not known in compact massive forms.

H. = 2·5—3. G. = 2·78—2·85. Lustre pearly, often submetallic, on cleavage surface. Color yellowish-brown to brownish-red, with often something of a copper-like reflection; also pale brownish-yellow, green, white, colorless. Transparent to translucent in thin folia. Thin laminæ tough and elastic. Optical-axial divergence 3°—20°, rarely less than 5°; in fig. 282, which represents the optical character of the mica of Natural Bridge, 15°.

Comp.—Mostly $(\frac{7}{11}\dot{R}^3+\frac{4}{11}\bar{R})^2\ddot{Si}^3$; the bases include magnesia and little or no iron. Possibly for all $(\frac{2}{3}\dot{R}^3+\frac{1}{3}\bar{R})^2\ddot{Si}^3$, as in anal. by Rammelsberg. Phlogopite is a true *Magnesia mica*.

Analyses: 1, Meitzendorff (Pogg., lviii. 157); 2–4, Craw (Am. J. Sci., II. x. 383); 5, Rammelsberg (ZS. G., xiv. 758); 6, Svanberg (Ak. H. Stockh., 1839, 176); 7, Delesse (Bull. G. Fr., II. ix. 121); 8, id. (Ann. d. M., V. x. 519); 9, C. Bromeis (Pogg., lv. 112):

[a] Includes 5·08 of $\mathrm{Fe}^2\mathrm{O}^3$. [b] Reckoned as 1·67 $\mathrm{Mn}^2\mathrm{O}^3$.

The Sala mica of No. 6 has not been examined optically; yet, as it agrees nearly in atomi proportions with phlogopite, it appears to belong here. It was dark green in color, and inelastic, and is called chlorite by Svanberg; the analysis is here cited from the original paper by Svanberg. Crawe's analyses afford the O. ratio 1·77 : 1 : 2·69=7 : 4 : 11, and Meitzendorff's nearly the same. The silico-fluorids in the former are about $\frac{1}{24}$, and in the latter $\frac{1}{30}$. G of No. 5, 2·81, Rammelsberg. Analysis 7, by Delesse, affords the O. ratio 3 : 2 : 5; and 8, about 4¼ : 3 : 9. The latter mica is a brown or greenish kind from the rock called by Delesse, Minette, occurring at Servance in the Vosges; the ratio may become that of biotite when the state of oxydation of the iron is ascertained; G.=2·842. No. 9 gives the ratio 12¼ : 6 : 22½; it is from near L. Laach.

Pyr., etc.—In the closed tube gives a little water. Some varieties give the reaction for fluorine in the open tube, while most give little or no reaction for iron with the fluxes. B.B. whitens and fuses on the thin edges. Completely decomposed by sulphuric acid, leaving the silica in thin scales.

Obs.—Phlogopite is especially characteristic of serpentine, and crystalline limestone or dolomite.

Occurs in limestone in the Vosges (anal. 7, 8). Includes probably the mica found in limestone at Alt-Kemnitz, near Hirschberg; that of Baritti, Brazil, of a golden-yellow color, having the optical angle 5° 30′ and parallel to the shorter diagonal (Grailich); and a brown mica from limestone of Upper Hungary, affording Grailich the angle 4°—5°.

Occurs at the following localities in the U. States; specimens from which afforded the optical angles annexed, all measured by B. Silliman, Jr. (Am. J. Sci., II. x. 372), excepting one by Blake (ib., xii. 6):

1. Pope's Mills, St. Lawrence Co., N. Y., glassy transparent	7°—7° 30′	B. S
2. Edwards, N. Y., rich reddish brown	10?	"
3. St. Lawrence Co.,? N. Y., yellowish	10?	"
4. Vrooman's Lake, N. Y., in long crystals of a yellow color	10 30—10 50	"
5. Edwards, N. Y., rich yellowish-brown color	11	"
6. Warwick, Orange Co., N. Y., in limestone, yellowish	11?	"
7. Falls of the Grand Calumet, Canada, yellowish-green crystals many inches long	13—13 12	"
8. Pope's Mills, St. Lawrence Co., N. Y., large crystals, fine yellowish-brown	13 30	"
9. Edwards, N. Y.; 2d specimen, yellowish-brown	13 30	"
10. Church's Mills, Rossie, N. Y., resembles the Pope's Mills	13 30—14	"
11. Near Skinner's Bridge, Rossie, N. Y., silvery-yellow mica	14	"
12. Carlisle, Mass., rich yellowish-brown	14	"
13. Rossie, N. Y., near Mrs. Story's, light yellowish	15	"
14. Pope's Mills, St. Lawrence Co., brownish-yellow hexagonal crystal	15	"
15. Natural Bridge, Jefferson Co., N. Y., rich yellow; associated with serpentine; same as analyzed by Meitzendorff	15	"
15. bis., ib., ib., another specimen	16	"
16. Edwards, N. Y., white silvery, curved crystals	15 30—16 30	"
17. Vicinity of Rossie, N. Y., rich yellow-brown; probably the same as Gouverneur	16 7—16 15	"
18. Essex, N. Y., in limestone, deep rich brown color	16 30	"
19. Upper Ottawa, Canada, reddish-yellow, transparent	17 30—18	"
20. Moriah, Essex Co., N. Y., very dark smoky red	Est'd 16—17	"
21. Somerville, N. Y., faint brownish	5—7	"
22. Burgess, Canada West, bronzy, almost metallic, semi-transparent if thin; opaque in plates a line thick; slightly elastic only; found with apatite in sandstone	Angle very small	‘

23. Franklin, N. J., bronzy-yellow	About 14°	R 8
24. Burgess, Canada West, whitish-yellow	About 10	"
25. Fine, St. Lawrence Co., N. Y., very dark olive-brown	Est'd 10—12	"
26. Amity, N. Y., opaque silvery white	10—12	"
27. Warwick, Pa., brownish olive-green	About 10	Blake.

Phlogopite occurs also at Gouverneur, N. Y., of a brownish copper-red; at Sterling Mine, Morris Co., N. J., rich yellowish-brown, inclining to red, in limestone; at Suckasunny mine, N. J., deep olive-brown, inclining to yellow, in limestone; Newton, N. J., yellow, in limestone; Lockwood, Sussex Co., N. J., deep olive-brown, like the mica of Fine, N. Y., in limestone; at St. Jerome, Canada, reddish-coppery. The crystals at Clarke's Hill, St. Lawrence Co., are very large, sometimes nearly two feet long; fig. 281 represents one in the cabinet of W. W. Jefferis, which is 20 in. long, 4 in. thick at top, and 8½ in. at centre, and weighs 57¼ pounds. Senarmont found one deep bottle-green mica of unknown locality having the angle 15°.

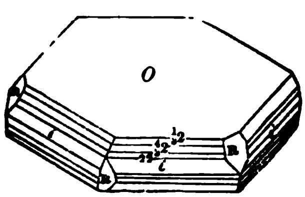
Named from φλογωπός, *fire-like*, in allusion to the color.

Alt.—The phlogopites are quite liable to change, losing their elasticity, becoming pearly in lustre, with often brownish spots, as if from the hydration of the oxyd of iron. In some cases an alteration to steatite and serpentine has been observed. A serpentine pseudomorph after phlogopite from Somerville, St. Lawrence Co., N. Y., afforded Lewinstein (ZS. Ch. Pharm., 1860, 15) $\ddot{Si}$ 47·24, $\bar{\bar{Al}}$ 2·32, $\dot{Mg}$ 33·23, $\dot{Fe}$ 1·10, $\dot{Na}$ 0·67, $\dot{K}$ 0·57, $\dot{H}$ 14·87=100.

289. BIOTITE. Magnesia-Mica pt., Hexagonal Mica, Uniaxial Mica. Astrites meroxenus (fr. Vesuv.) *Breith.*, Handb., 382, 1841. Rubellan=Astrites trappicus, *Breith.*, ib. 379. Biotit *Hausm.*, Handb., 671, 1847. Rhombenglimmer (fr. Greenwood Furnace) *Kenngott*, Pogg., lxxiii. 661.

Hexagonal. $R \wedge R=62° \ 57'$, crystals fr. Vesuvius, Hessenberg; $a=4·911126$. Habit often monoclinic. Observed planes: O; rhombohedrons, R, $\frac{2}{5}$, $-\frac{1}{2}$; prism, i-2; pyramids, $\frac{1}{3}$-2, $\frac{4}{9}$-2, $\frac{2}{3}$-2, 1-2, $\frac{4}{3}$-2, 2-2, $\frac{8}{3}$-2, $\frac{10}{3}$-2, 4-2; $\frac{2}{5}$-R the form fr. Greenwood Furnace, the rest fr. Vesuvian crystals.

283



$O \wedge R=100°$
$O \wedge \frac{1}{3}\text{-}2=121 \ 25'$
$O \wedge \frac{2}{3}\text{-}2=106 \ 59$
$O \wedge 1\text{-}2=101 \ 30\frac{1}{2}$
$O \wedge \frac{4}{3}\text{-}2=98° \ 41'$
$O \wedge 2\text{-}2=95 \ 49$
$O \wedge 4\text{-}2=92 \ 55$
$O \wedge \frac{2}{5}=113 \ 47$

Prisms commonly tabular. Cleavage: basal highly eminent. Often in disseminated scales, sometimes in massive aggregations of cleavable scales.

H.=2·5—3. G.=2·7—3·1. Lustre splendent, and more or less pearly on a cleavage surface, and sometimes submetallic when black; lateral surfaces vitreous when smooth and shining. Colors usually green to black, often deep black in thick crystals, and sometimes even in thin laminæ, unless the laminæ are very thin; such thin laminæ green, blood-red, or brown by transmitted light; rarely white. Streak uncolored. Transparent to opaque. Optically uniaxial. Sometimes biaxial with slight axial divergence, from exceptional irregularities, but the angle not exceeding 5° and seldom 1°.

Comp., Var.—Biotite is a magnesia-iron mica, part of the alumina being replaced by sesquioxyd of iron, and protoxyd of iron and magnesia existing among the protoxyd bases. Black is the prevailing color, but brown to white also occur. The results of analyses vary much, and for the reason already stated—the non-determination, in most cases, of the degree of oxydation of the iron; and the exact atomic ratio for the species and its limits of variation are therefore not precisely understood. The O. ratio, which appears to be dominant, is 1 : 1 : 2, giving the formula $(\frac{1}{2}\dot{R}^3+\frac{1}{2}\bar{R})^2\ddot{Si}^3$, which is the formula of garnet. In some cases the ratio is apparently nea

1 : 1½ : 2½ and 1 : 2 : 3; and through species containing much iron it passes to micas of the species annite and lepidomelane.

The analyses below are arranged in two divisions; (A) having the O. ratio approximately 1 : 1 : 2; (B) having other various ratios.

Analyses: A. 1, v. Kobell (Kastn. Arch. Nat., xii. 29); 2, 3, Smith & Brush (Am. J. Sci., II. xvi. 45); 4, v. Hauer (Ber. Ak. Wien, xii. 485); 5, Smith & Brush (l. c.); 6, J. L. Smith (Am. J. Sci., II. xlii. 91); 7, v. Kobell (l. c.); 8, v. Kobell (J. pr. Ch., xxxvi. 309); 9, Bromeis (Pogg., lv. 112); 10, Chodnef (Pogg., lxi. 381); 11, Chodnef, with oxyd of iron by Mitscherlich (J. pr. Ch., lxxvi. 1); 12, Kjerulf (J. pr. Ch., lxv. 187); 13, H. Rose (Gilb. Ann., lxxi. 13); 14, C. Bromeis (Bischof's Lehrb. Geol., ii. 1418); 15, Bukeisen (Kenng. Ueb., 1856–57, 86); 16, Scheerer (ZS. G., xiv. 60); 17, Kiebel (ib.); 18, A. Streng (B. H. Ztg., xxiii. 54); 19, Klaproth (Beitr., v. 78); 20, H. Rose (Pogg., i. 75); 21, v. Kobell (Kastn. Arch. Nat., xii. 29).

B. 22, 23, Scheerer and Rube (ZS. G., xiv. 56); 24, Varrentrapp (Pogg., lxi. 381); 25, Delesse (Ann. Ch. Phys., III. xxv. 14); 26, Svanberg (Ak. H. Stockholm, 1839, 172); 27, Kjerulf (l. c.); 28, Svanberg (l. c., 177); 29, Haughton (Q. J. G. Soc., xviii. 413); 30, H. Rose (No. 20 above), 31, v. Kobell (No. 21 above), with Mitscherlich's determination of the iron.

31. "	42·12	12·83	2·53	15·32	——	16·15	——	——	8·58	1·07	——	=98·60 K.

In anal. 5, G.=2·80, the mica talc-like, pale ywh.-gn. by transmitted light, inelastic, waxy, probably somewhat altered; 6, chlorite-like, with emery, etc.; 8, G.=2·7; 16, 17, from the Erzgebirge; 18, from gabbro, opt. char. not given; 22, 23, bronze-brown to black, in gneiss; 25, out of protogine of Alps; 29, from granite, Ireland.

In the Vesuvian biotite, anal. 12, O. ratio for $\dot{\mathrm{R}}$, $\dddot{\overline{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$=10·05 : 10·36 : 23·17; anal 10, 9·37 : 12·38 : 21·24=1 : 1⅓ : 2⅓; anal. 11 (10 as modified by Mitscherlich), 9·25 : 9·93 : 21·24. Anal. 16, as it stands, gives the ratio 1 : 1½ : 2½; 18, 1 : 1 : 1¾; 22 to 29, nearly 1 : 2 : 3, but some deficiency of protoxyds in 27, 28, making the ratio nearer 1 : 2⅔ : 4. The last two, 30, 31, are the analyses by Rose and v. Kobell, Nos. 20, 21, with the $\dot{\mathrm{Fe}}$ and $\dddot{\overline{\mathrm{Fe}}}$ as recently determined by A. Mitscherlich. Mitscherlich's results change the ratio from 1 : 1 : 2 to nearly 5 : 3 : 10, or the ratio approximately of phlogopite; and if his determination should be sustained, the Siberian mica analyzed would appear to be phlogopite.

A *chrome magnesia mica* (*Chromglimmer*) of a green color, from Schwarzenstein, in Zillerthal, afforded Schafhäutl (Ann. Ch. Pharm., xlvi. 325) over 5 p. c. of oxyd of chromium, and the O. ratio for the whole 6·4 : 9·6 : 24·75=2 : 3 : 8. He obtained $\ddot{\mathrm{Si}}$ 47·68, $\dddot{\overline{\mathrm{Al}}}$ 15·15, $\dddot{\overline{\mathrm{Cr}}}$ 5·90, $\dddot{\overline{\mathrm{Fe}}}$ 5·72, $\dot{\mathrm{Mn}}$ 1·05, $\dot{\mathrm{Mg}}$ 11·58, $\dot{\mathrm{Na}}$ 1·17, $\dot{\mathrm{K}}$ 7·27, $\dot{\mathrm{H}}$ 2·86=98·38.

Pyr., etc.—Same as phlogopite, except that with the fluxes it gives strong reactions for iron.

Obs.—Biotite was first shown to be optically *uniaxial* by Biot, after whom it is named; and later, to be hexagonal in crystallization by Marignac (Bibl. Univ., 1847, Suppl. vi. 300); Brooke and Miller (Min., 387); Kokscharof (Min. Russl., ii. 291); and quite recently, and after careful measurements, by Hessenberg (Min. Not., No. vii. 15, 1866). But still the crystals are often slightly biaxial, as first remarked by Silliman (Am. J. Sci., II. x. 372, 1850), and W. P. Blake (ib., xii. 6, 1851); and later by Dove (Ber. Ak. Berlin, 1853), Senarmont (Ann. Ch. Phys., III. xxxiii. 391, xxxiv. 171), Grailich (Lehrb. d. Kryst., 1856), and others. On the ground of the biaxial character observed, Descloizeaux, in his Min., i. 88, 1862, made the species orthorhombic. Blake examined specimens from Greenwood Furnace; a silvery-white var. fr. Easton, Pa.; a crimson from Topsham, Me.; a fiery-red, by transmitted light, from Moriah, Essex Co., N. Y.; a dark bottle-green from Moor's Slide, Ottawa, Canada; and seven different varieties from Vesuvius. But the divergence, which was in all very small, was not measured. One of the uniaxial micas examined by Biot is stated by him to have come from Topsham, Me. Kokscharof found some crystals from Vesuvius true uniaxial.

The following are the results of measurements by Senarmont and Grailich (two or three of the micas perhaps phlogopites):

1. *Axial plane parallel to the longer diagonal.*

1. Greenwood Furnace	0°—1°	Grailich.
2. Pellegrino, Tyrol; hexagonal; in limestone	0 —1	"
3. Karosulik, Greenland; sea-green	1 —2	Grailich.
4. Lake Baikal; dark brown	1 —2	"
5. Adun-Tschilon, Siberia; reddish-brown, in dolomite (phlogopite?)	1 —2	"
6. Ceylon; clear green, transparent	1 —2	Senarmont.
7. Philadelphia; clear olive-green (phlogopite?)	2 —4	"

2. *Axial plane parallel to the shorter diagonal.*

1. Vesuvius; so-called meroxene	0°—1°	Grailich.
2. Vesuvius; dull green to colorless	1	"
3. Vesuvius; brownish-green	2	"
4. Vesuvius; bluish	3	"
5. Vesuvius; greenish-black in pumice	4	"
6. L. Baikal; deep brown, transparent, hexagonal	1	Senarmont.

7. Easton, Pa.; silvery white	1°—2°	Grailich.
8. Fassa, Tyrol; resembling meroxene	1 —3	"
9. Easton, Pa.; green	3 —4	"

Grailich found the angle 0°, or zero, in mica from Zillerthal; Norway, dark green; Kariat dark olive-green; Retzbanya, greenish to colorless; Goshen, pistachio-green; Leonfelden, black; Magura, dark red; Altenberg, dark bluish; Horn, black; Besztercze, dark; Anaksirksarklich, liver-brown.

The Vesuvian biotite found on Mt. Somma (Meroxene of Breith.) occurs in brilliant crystals with numerous polished facets. Other foreign localities are named in connection with the analyses. The mica from Greenwood Furnace, Monroe, N. Y., analyzed by von Kobell (anal. 1), occurs in large and very regular rhombic prisms (sometimes 5 or 6 in. across) oblique from an *acute* edge; and also in tetrahedral pyramids; the faces of the pyramids incline to the cleavage plane at 113° to 114°; v. Kobell gives for the angle R ∧ R (faces of the pyramid) 71° to 72°. This is the same mica with that analyzed by Smith and Brush (anal. 2, 3), as Prof. Brush has assured himself by an examination of von Kobell's specimens at Munich.

Alt.—*Rubellan* is considered an altered biotite; it occurs in small hexagonal forms, of a red color, in a kind of wacke. Steatite is also a result of the alteration of this species, as in granite at Brünn and Thierscheim. Among the above analyses, several indicate incipient change by the water and chlorine present. Mica, altered to magnetite, has been observed in the Tyrol.

The *Eukamptite* of Kenngott (Ueb., 1853, 58, 1855, and described under the name *Chlorit ähnliches Mineral* in Ber. Ak. Wien, xi. 609, 1853) is a hydrous biotite, probably a result of alteration, from Presburg, Hungary. It is between mica and chlorite in its characters. Color nearly black, but in very thin folia brown to hyacinth-red or reddish-yellow; H.=2—2·5; G.=2·73 Composition, according to an analysis by v. Hauer (l. c.). S̈i 38·13, A̶l 21·60, Ḟe 19·92, Ṁn 2·61, Ṁg, by loss, 13·76, Ḣ 3·98=100, giving the oxygen ratio for Ṙ, R̶, S̈i, Ḣ=1 : 1 : 2 : ⅓. The *Voigtite* of Schmid may also be a hydrated biotite. See under HYDROUS SILICATES, p. 393.

290. LEPIDOMELANE. *Hausmann*, Gel. Anz. Gött., 945, 1840.

Hexagonal? In small six-sided tables, or an aggregate of minute scales. Cleavage basal, eminent, as in other micas.

H.=3. G.=3·0. Lustre adamantine, inclining to vitreous, pearly. Color black, with occasionally a leek-green reflection. Streak grayish-green. Opaque, or translucent in very thin laminæ. Somewhat brittle, or but little elastic. Optically unaxial; or biaxial with a very small axial angle.

Comp.—An iron-potash mica. O. ratio for bases and silica 1 : 1; for Ṙ, R̶, mostly 1 : 3, but varying to 1 to more than 3; of doubtful limits, on account of the doubts as to the state of the iron in most of the analyses. 1 : 3 for the ratio of Ṙ, R̶ gives $(\tfrac{1}{4}\dot{R}^3+\tfrac{3}{4}\ddot{\ddot{R}})^2\ddot{Si}^3$. Differs from biotite in the smaller proportion of protoxyds and little alumina and magnesia, but appears to agree with it in optical characters.

Analyses: 1, Soltmann (Pogg., l. 664); 2, Svanberg (Ak. H. Stockh., 178, 1839); 3–7, Haughton (J. G. Soc., xv. 129, xviii. 418, Phil. Mag., IV. xviii. 259); 8, Illing (Gieb. u. Heintz, ZS. Nat., 1854, 339).

The original lepidomelane, anal. 1, affords the O. ratio 1 : 3 : 4. The Irish variety (anal. 4, 5, 6, 7) affords as a mean result, 1 : 3·3 : 4·1; No. 4 is from Ballyellin, and 5, 6, from Donegal Co. The Abborforss mica affords 1 : 4·6 : 6·2; but if the water be made basic, 1 : 3·1 : 4·3; and anal. 8 corresponds to 1 : 3·2 : 3·8; both near 1 : 3 : 4. The mineral of the last has G.=3·96, and is very fusible.

Pyr., etc.—B.B. at a red heat becomes brown and fuses to a black magnetic globule. Easily decomposed by muriatic acid, depositing silica in scales.

Obs.—A scaly-massive mineral at Persberg in Wermland, Sweden, containing imbedded prisms of hornblende, the scales half a line or so across; mica-like at Abborforss in Finland; in granite in Ireland, at Ballyellin in Carlow Co., Leinster, at Ballygihen in Donegal Co., and at Canton, mostly in largish crystals or plates (¼ inch across and larger). The Donegal and Leinster Co. mica is optically uniaxial, according to Haughton. The granite contains also a white muscovite (see anal. 8–11, under Muscovite); and in some cases the black and white form parts of the same crystal; and, where so, the optic-axial divergence of the muscovite was diminished, according to some trials, 20°. Named from λεπίς, *scale*, and μέλας, *black*.

Alt.—Haughton gives the following as the composition of an altered form of the black mica of Donegal Co., Ireland (Nos. 5, 6, above); it was from Castlecaldwell: S̈i 31·60, Ä̶l 19·68, F̶̈e 28·35, Ḟe 4·04, Ṁn 1·20, Ṁg 7·03, Ċa 0·45, Ṅa 0·74, K̇ 3·90, Ḣ 8·68=100·67. It approaches a chlorite.

Pterolite of Breithaupt (B. H. Ztg., xxiv. 336) appears to be an altered lepidomelane, of a pearly lustre, and a color between olive-green and liver-brown; scaly massive in texture. In the analysis by R. Müller he found part of the mineral soluble in heated muriatic acid and part not; and in analyses of the whole and the parts separately, the following results:

	S̈i	Ä̶l	F̶̈e	Ḟe	Ṁg	Ċa	Ṅa	K̇	Ḣ
1. The whole	39·38	6·65	19·89	16·43	0·56	5·47	2·81	7·86	1·39
2. Sol. part	36·08	4·99	25·98	14·28	—	5·43	3·68	7·96	1·31
3. Insol. part	50·14	12·03	—	23·43	—	6·88	—	7·52	—

The O. ratio for the soluble part is 2 : 3 : 5; for the insoluble, 3 : 2 : 10. It occurs at Brevig, Norway, with astrophyllite, wöhlerite, ægirite, etc.

A Brevig mica afforded A. Dufrance (ZS. G., xiv. 100) S̈i 35·93, Ä̶l 10 98, F̶̈e 9·82, Ḟe 26·93, Ṁn 0·72, Ṁg 5·13, Ċa 1·04, Ṅa 5·18, K̇ 0·24, Ḣ 4·30, T̈i 0·99=101·26. It is probably an altered mica, as shown by the amount of soda present.

Bastonite is a mica in large plicated plates, of a greenish-brown color, greasy lustre, very small optical angle, easily fusible into a black enamel, discovered by Dumont in a quartzite from Bastoigne, Duchy of Luxembourg (Descl. Min., 498, 1862).

A brownish-black mica from Renchthal, in the Schwarzwald, with slight optic-axial angle and pearly metalloidal lustre, afforded Nessler (Jahresb., 1863, 820) S̈i 38·34, Ä̶l 33·80, F̶̈e 13·73, Ḟe 7·40, Ṁg 0·36, Ṅa 0·56, K̇ 4·22, Ḣ 1·36, F *tr.*, T̈i 0·60=100·37.

291. Annite *Dana*. The lepidomelane of Cape Ann, described and analyzed by J. P. Cooke (Am. J. Sci., II. xliii. 222), differs, according to the analyses, in having the O. ratio 1 : 2 : 3, instead of 1 : 3 : 4. In optical and other physical characters it is like lepidomelane. It occurs in plates and disseminated scales; H.=3; G.=3·169; color black; streak dark green; opaque, except in very thin folia. Cooke obtained:

	S̈i	Ä̶l	F̶̈e	M̶̈n	Ḟe	Ṁg	L̇i	K̇	Ṅa, Ṙb	Ḣ	SiF^3
A. (⅔)	39·55	16·73	12·07	0·60	17·48	0·62	0·59	10·66	*tr.*	1·50	0·62=100·42.
B.	37·39	16·66	13·74	0·64	19·03	0·59	—	10·20	—	1·75	—=100.

Anal. B is deduced from A on the supposition that the mineral was mixed intimately (as a result of contemporaneous crystallization) with cryophyllite, an associated species at the locality, and that the amount of lithia indicated the proportion of cryophyllite. O. ratio deduced for the latter for Ṙ, R̶̈, S̈i, Ḣ=6·2 : 12·1 : 19·9 : 1·6. It may be found that the biotites having the O. ratio for Ṙ, R̶̈=1 : 2 should be here placed.

Occurs in the Cape Ann granite, with cryophyllite, orthoclase, albite, and zircon (cyrtolite).

292. ASTROPHYLLITE. Astrophyllit *Scheerer*, B. H. Ztg., xiii. 240, 1854.

Orthorhombic; habit monoclinic. $I \wedge I = 120°$. Usually in tabular prisms; often lengthened into strips with parallel sides in the direction of the shorter diagonal. Observed form a narrow tabular crystal, terminating in front in two planes of an octahedron, and below these one of a macrodome; the front angle of the former 160°, and the edge between the planes inclined to *O* 125°; *O* on the macrodome 130°. Cleavage: basal eminent. Sometimes in stellate groups.

H.=3. G.=3·324, Pisani. Lustre submetallic, pearly. Color bronze yellow to gold-yellow. Powder resembling that of mosaic gold. Translu cent in thin leaves. Laminæ only slightly elastic. Optic-axial divergence 118°—124°; bisectrix normal to the cleavage-surface; Descl.

Comp.—Perhaps $(\dot{R}^3,\ddot{\ddot{R}})^2\,\ddot{S}i^3$, the titanium oxyd being included with the bases. The protoxyds include prot. of iron and manganese, with potash, soda, etc.; the sesquioxyds those of iron and aluminum; the deutoxyds that of titanium, and perhaps that of zirconium. Analyses: 1, Pisani (C. R., lvi. 846); 2, 3, 4, Scheerer, Meinecke, and Sieveking (Pogg., cxxii. 113):

	$\ddot{S}i$	$\ddot{T}i$	$\ddot{Z}r$	$\ddot{\ddot{A}}l$	$\ddot{\ddot{F}}e$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{L}i$	$\dot{N}a$	$\dot{K}$	ign.	
1.	33·23	7·09	4·97	4·00	3·75	23·58	9·90	1·27	1·13	tr.	2·51	5·82	1·86=99·11	P.
2.	32·21	8·24	——	3·02	7·97	21·40	12·63	1·64	2·11	——	2·24	3·18	4·41=99·05	S.
3.	32·35	8·84	——	3·46	8·05	18·06	12·68	2·72	1·86	——	4·02	2·94	4·58=99·51	M.
4.	33·71	8·76	——	3·47	8·51	25·21	10·59	0·05	0·95	——	3·69	0·65	4·85=100·44	S.

Pisani's analysis gives for the O. ratio of $\dot{R}$, $\ddot{R}$, $\ddot{\ddot{R}}$, $\ddot{S}i$, $\dot{H}$, 9·78 : 4·07 : 2·99 : 17·72 : 1·65=approximately (water excluded) 10 : 4 : 3 : 17; or for bases and silica 1 : 1; and Sieveking's analysis affords 9·28 : 4·17 : 3·42 : 17·97 : 4·31=(water excluded) 1 : 1 for bases and silica.

Pyr., etc.—B.B. swells up and fuses easily to a black magnetic enamel. With soda or borax, a strong manganese reaction. Decomposed by muriatic acid with a separation of silica in scales.

Obs.—Occurs at Brevig, Norway, in zircon-syenite, imbedded in lamellar feldspar, and associated with catapleiite, and large prisms of black mica.

293. **MUSCOVITE.** Common Mica; Potash Mica; Biaxial Mica; Oblique Mica. Glimmer, Zweiaxiger Glimmer, *Germ.* Muscovite *Dana*, Min., 356, 1850. Phengit *v. Kob.*, Taf., 62, 1853. Nacrite (fr. Maine) *Thom.*, Rec. Gen. Sci., 332, 1836. Fuchsite, Chromglimmer pt., *Schafhäutl*, Ann. Ch. Pharm., xliv. 40, 1842. Talcite (fr. Wicklow) *Thomson*, Rec. Gen. $O \wedge 1=106\ 53\frac{1}{2}$	$O \wedge 6\text{-}\breve{i}=92\ 54$	$O \wedge 6\text{-}\breve{3}=92\ 31$

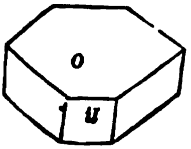
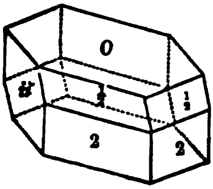
284

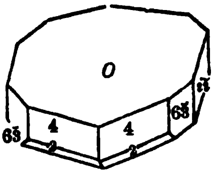


285



Miask, Ural.

286



Binnen Valley.

Cleavage: basal eminent; occasionally also separating in fibres parallel to a diagonal. Twins: often observable by internal markings, or by polarized light; composition parallel to I consisting of six individuals thus united; sometimes a union of I to $i\text{-}\breve{i}$. Folia often aggregated in stellate, plumose, or globular forms; or in scales, and scaly massive.

H.=2—2·5. G.=2·75—3·1. Lustre more or less pearly. Color white, gray, brown, hair-brown, pale-green, and violet, yellow, dark olive-green rarely rose-red; often different for transmitted and reflected light, and different also in vertical and transverse directions. Streak uncolored. Transparent to translucent. Thin laminæ flexible and elastic, very tough Double refraction strong; optic-axial angle 44°—78°.

Comp.—O. ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$ 1 : 1¼; rarely 1 : 1⅓, and for $\dot{R}$, $\bar{R}$ either, approximately, 1 : 6, 1 : 9, or 1 : 12; $\dot{R}$=potash ($\dot{K}$) almost solely. These ratios may hereafter prove to be different after a correct determination in each case of the degree of oxydation of the iron. Fluorine is present, but not over 1 p. c. has in any case been detected.

Water is often present, especially where the latter ratio is 1 : 6 or 1 : 9; and it sometimes amounts to 5 p. c.; and the kinds containing 3 to 5 p. c. of water have been referred to the species *Margarodite;* making the water basic in such kinds, the O. ratio for bases and silica becomes 1 : 1, as in other unisilicates. The hydrous kinds so graduate into the anhydrous that the analyses are here brought all together, although the species *margarodite* is introduced on page 487. The ratio 1 : 1¼ may indicate that muscovite is a combination of 3 parts of a unisilicate and 2 of a bisilicate, as in the formula $3\,(\dot{R}^3, \bar{R})^2\,\ddot{Si}^3 + 2\,(\dot{R}^3, \bar{R})\,\ddot{Si}^3$. But if the mineral is a true unisilicate, as its relation to biotite and phlogopite would indicate, but with an excess of silica, the formula may be $(\dot{K}^3, \bar{R})^2\,\ddot{Si}^3 + 1\frac{1}{4}\,\ddot{Si}$; or else with half the excess of silica basic. With the O. ratio 1 : 6 for $\dot{R}$ and $\bar{R}$, the bases correspond to $\frac{1}{7}\dot{K}^3+\frac{6}{7}\bar{R}$; with 1 : 9, to $\frac{1}{10}\dot{K}^3+\frac{9}{10}\bar{R}$; with 1 : 12, to $\frac{1}{13}\dot{K}^3+\frac{12}{13}\bar{R}$.

The analyses are here arranged in groups; *first*, according as the oxygen ratio between the bases ($\dot{R}+\bar{R}$) and silica ($\ddot{Si}$) is 1 : 1¼, or 1 : 1⅓; and *subordinately*, into those in which the oxygen ratio between the protoxyds ($\dot{R}$) and sesquioxyds ($\bar{R}$) is either 1 : 6 approximately, or 1 : 9, or 1 : 12. It is to be remarked that the incipient alteration of a mica, attended with the introduction of a little magnesia, lime, or soda ($\dot{Mg}$, $\dot{Ca}$, or $\dot{Na}$), with a removal or not of some potash ($\dot{K}$), might increase the proportion of protoxyds and thus change the latter ratio from 1 : 12 to 1 : 6, or produce the intermediate gradations.

Analyses: A. 1. *O. ratio of* $\dot{R}$, $\bar{R}$, 1 : 6; 1, Delesse (Ann. d. M., IV. xvi. 202); 2, Rammelsberg (Pogg., lxxxi 38); 3, Schafhäutl; 4–6, Smith & Brush (Am. J. Sci., II. xvi. 46, 47, xv. 210); 7, 8, Haughton (Phil. Mag., IV. ix. 272); 9, Sullivan (J. G. Soc. Dublin, iv. 155); 10–13, Haughton (l. c., and Q. J. G. Soc., xviii. 414, xx. 280).

30. "	51·73	28·75	5·87	0·62	——	2·14	8·28	——	0·83=99·72 Kjerulf.
31. Pargas	50·10	28·05	5·46	0·40	2·41	1·26	7·56	3·87	——=99·11 Rath.

In anal. 1, G.=2·817, grayish-white, in graphic granite; 2, G.=2·831, silver-white, with black tourmaline; 4, 5, with topaz and fluorite; 6, G.=2·76, colorless, pearly, with cyanite; 8, G.=2·793, gray, silvery, trp.; 10, gray, silvery, trp.; 14, G.=2·817, white; 15, white, pseud. after andalusite; 16, 18, G.=3·123, in hexag. scales, from granite, opt. char. not given; 19, G.=2·802, in coarsely grouped masses of intersecting laminæ; 20, G.=2·85; 28, G.=2·86; 29, G.=2·867, green, pseud. after orthoclase; 30, pseud. after orthoclase; 31, G.=2·833, silvery white, 11·11, Ċa C̈ removed, pseud. after scapolite.

The rose-colored micas of Goshen, Mass., afforded Mallet (Am. J. Sci., II. xxiii. 180) K̇ 9·08, Ṅa 0·99, L̇i 0·64.

A greenish-black mica, constituting a micaceous schist or rock in Derby, Vt.—the so-called *Adamsite* of Shepard—consists, according to G. J. Brush (Am. J. Sci., II. xxxiv. 216), S̈i 47·76, A̶l and F̶e 36·29, Ċa 0·24, Ṁg 1·85, alkalies (by loss) 8·77, ign. 5·09, and has all the ordinary characters of common mica.

Thomson gives for the composition of a mica reported to come from Orange Co., N. Y. (Min., i. 360) S̈i 49·38, A̶l 23·67, F̶e 7·31, K̇ 15·29, Ċa 6·13, L̇i 0·06=101·89. Little reliance can be placed on the analysis.

A schist, formerly called *talcose schist*, from Zillerthal in Tyrol, and named *didymite* by Schafhäutl (Ann. Ch. Pharm., 1843, J. pr. Ch., lxxvi. 136, not *didrimite*, as sometimes written) is near muscovite in its composition. It is feeble pearly, and grayish-white in color; H.=1·5—2; G.=2·75. Schafhäutl obtained S̈i 40·69, A̶l 18·15, F̶e 5·25, Ṅa 1·23, K̇ 11·16, Ḣ 0·60, Ċa C̈ 22·74—99·82. It has also been called *amphilogite*. Probably only a mica schist.

A variety of muscovite (1) composed of scales arranged in plumose forms is called *plumose* mica; and another (2) having a diagonal cleavage, cleaving sometimes into thread-like pieces, *prismatic* mica. An emerald-green variety (3) is the *fuchsite* or chrome-mica, containing sometimes nearly 4 p. c. of oxyd of chrome.

Pyr., etc.—In the closed tube gives water, which with brazil-wood often reacts for fluorine. B.B. whitens and fuses on the thin edges (F.=5·7, v. Kobell) to a gray or yellow glass. With fluxes gives reactions for iron and sometimes manganese, rarely chromium. Not decomposed by acids. Decomposed on fusion with alkaline carbonates.

Obs.—Muscovite is the most common of the micas. It is one of the constituents of granite, gneiss, mica schist, and other related rocks, and is occasionally met with in granular limestone, trachyte, basalt, lava; and occurs also disseminated sparingly in many fragmental rocks. Coarse lamellar aggregations often form the matrix of topaz, tourmaline, and other mineral species in granitic veins.

Siberia affords laminæ of mica sometimes exceeding a yard in diameter; and other remarkable foreign localities are at Finbo in Sweden, and Skutterud in Norway. See above for other localities. *Fuchsite* or *chrome* mica occurs at Greiner in the Zillerthal, at Passeyr in Tyrol, and on the Dorfner Alp, as well as at Schwarzenstein.

In *N. Hamp.*, at Acworth, Grafton, and Alstead, in granite, the plates at times a yard across and perfectly transparent. In *Maine*, at Paris; at Buckfield, in fine crystals; at Unity, of a green color, on the estate of James Neal (Thomson's *naorite*, wrongly referred to Brunswick). In *Mass.* at Chesterfield. with tourmaline and albite; at Barre and South Royalston, in two localities, with beryl; at Mendon and Brimfield; at Chester, Hampden Co., faint greenish; at Goshen, rose-red (sometimes misnamed lepidolite); prismatic mica, at Russell. In *Conn.*, at Monroe, of a dusky-brown color, having internal hexagonal bands of a darker shade; at Trumbull, at the topaz vein in coarse radiated aggregations (called margarodite); at Litchfield, with cyanite, colorless and pearly (margarodite), G.=2·76; in brown hexagonal crystal at the Middletown feldspar quarry; at Haddam, pale brownish, with columbite, and also similar at another locality with garnets. In *N. York*, 6 m. S.E. of Warwick, crystals and plates sometimes a foot in diameter, in a vein of feldspar; a mile N.W. of Edenville, in six-sided and rhombic prisms; silvery, near Edenville; in St. Lawrence Co., 8 m. from Potsdam, on the road to Pierrepont, in plates 7 in. across; town of Edwards, in large prisms, six-sided or rhombic; Greenfield, near Saratoga, in reddish-brown crystals with chrysoberyl; on the Croton aqueduct, near Yonkers, in rhombic prisms with a transverse cleavage. In *Penn.*, in fine hexagonal crystals of a dark brown color at Pennsbury, near Pennsville, Chester Co; at Unionville, whitish; Delaware Co., at Middletown, smoky brown with hexagonal internal bands, which are due to magnetite (see p. 150); at Chesnut Hill, near the Wissahiccon, a green variety; at Leiperville, Delaware Co., faint greenish. In *N. Jersey*, in crystals at Newton and Franklin. In *Maryland*, at Jones's Falls, a mile and three-quarters from Baltimore; the plates show by transmitted light a series of concentric hexagons, the sides of which are parallel with the sides of a hexagonal prism.

Marignac obtained $O \wedge 4 = 94^\circ\ 50'$, and $O \wedge 2 = 98^\circ\ 30'$ (fig. 286); $O \wedge 1 = 107^\circ\ 5'$, from a Vesuvian crystal. Kokscharof $O \wedge 1 = 106^\circ\ 53'\ 30''$, Vesuvian crystal; Zepharovich 107° 3′ for the same angle, and 116° 18′ for $O \wedge \tfrac{2}{3}\text{-}i$ (Ber. Ak. Wien, liv. 286).

The following table contains the optic-axial angle, as measured in the air, for various muscovites:

1. *American*; as measured by B. Silliman in 1850 (l. c.).

	Apparent Angle.
1. New York Island, 4 m. from city, violet-gray	56° 20′—56° 40′
2. Royalston, Mass., dark brown, fine crystal	57 30
3. ib. ib. ib. ib. another	58—59
4. Pennsbury, Penn., smoky brown, striated	59
5. Philadelphia, greenish-gray, banded	60 30—61
6. ib., near Fairmount, smoky brown, resembles No. 4	60—62 30
7. Oxford, Maine, light brown	62 42—63
8. Monroe, Conn., brown with patches	64 30—65 30
9. Royalston, Mass., violet-brown, in thick plates	65
10. Local. ?; greenish-gray; in crystals	65 30—66
11. Falls road, 2½ m. from Baltimore, transparent brown	65 30—65 40
12. Near Ellicott's Mills, Md., ib. ib.	66 30
13. "Jones Falls," near Baltimore, blackish-green, symmetrically banded	66 15—66 30
14. Greenfield, Conn., greenish-yellow	66 30—67
15. Haddam, Conn. (Quarry Hill), clear brownish-green	67
16. Grafton, New Hampshire, light brown, transparent	67 30
17. Unionville, Penn., white, corundum locality	67—67 28
18. Acworth, N. H., greenish-gray, in granite.	67 15—67 30
19. Grafton, N. H., another specimen, light brown, with quartz and tourmaline	68 5—68 20
20. Templeton, Mass., transparent brown	69 30—69 40
21. Orange, Mass., ib. ib., beautiful crystals	69 30—69 40
22. Willimantic Falls, Conn., brownish-green, transparent	69 30—69 50
23. Pennsbury, Penn., brown crystals; another locality	69 27—70
24. Royalston, Mass., dark brown; 2d locality	69 40—70
25. Grafton, N. H., light brown; 3d specimen	69—69 30
26. Middletown, Conn., brownish, feldspar quarry	70—70 30
27. Chester, Hampden Co., Mass., greenish-white	70—70 30
28. Norwich, Mass., greenish-yellow; spodumene locality	70 20
29. Pennsbury, Penn. (3d local.), brownish-green	70—70 30
30. Goshen, Mass., greenish-yellow, with spodumene	70—70 30
31. Greenfield, N. Y., brownish; chrysoberyl locality	70 45—71
32. Haddam, Conn., brownish; in large plates	70

	Apparent Angle
33. Gouverneur, N. Y., brownish-white, in boulder	70°
34. Templeton, Mass. (2d spec.), transparent brown	70 15′
35. Leiperville, Del. Co., Pa., faint greenish, plicated	70 30—71
36. Jefferson Co., N. Y., greenish; in a boulder	71—71 30
37. Hebron, Maine, light brown, transparent	71 40—71 50
38. Norwich, Mass., yellowish-green, transparent	71 45
39. Haddam, Conn., ib.; columbite locality	71 30—71 45
40 E. Chester, Westchester Co., N. Y., yellowish-green boulder	71 30—72
41. Paris, Maine, ib.	72 15—72 30
42. ib., ib. ib.	72 30
43. Brunswick, Maine, whitish-brown, silvery	72 37—72 50
44. Gouverneur, N. Y.?, rose color; no lithia	73—73 5
45. Orange, N. H., gray, with flattened tourmaline, quartz, and feldspar	73—74
46. Pounal, Maine, nearly colorless; lithia? mica	74 50—75
47. Goshen, Mass., yellowish-green, with indicolite	75
48. ib. ib. ib. ib.	75 30—76
49. Lenox, Mass., rose-colored, with albite	75—75 30

2. Muscovites, measured by Senarmont, Grailich, etc.

(1) *Optical axes situated in the plane of the longer diagonal.*

	Appar. Angle	
1. Philadelphia; transparent; clear olive-green	57—58	Sen.
2. Siberia, in white quartz; silvery, imperf. transparent	57—58	"
3. Arendal, greenish-brown	58	Grailich
4. Zillerthal, in albite; silvery, imperf. transparent	58—59	Sen.
5. Arendal, in a feldspathic rock; transparent; pale	58—59	"
6. Loc. ——?; transparent; clear brown	58—59	"
7. Warwick; yellowish-brown	59	Grailich
8. Couzeran?; silvery, greenish-gray, with concave surface of cleavage	60	Sen.
9. St. Gothard, in quartzose gneiss; hexag.; silvery; clear gray	60	"
10. Schwarzenbach, Austria, pale green	61 12	Grailich
11. Miask; transparent; clear olive-green	62—63	Sen.
12. Katherinenburg; transparent; clear pale rose	63—64	"
13. Nertschinsk	65	Grailich
14. Rothenkopf, Tyrol; green	66	"
15. Gloria, near Rio Janeiro, Brazil; colorless	66 36	"
16. Schaitansk; imperfectly transparent; rose-colored	67	Sen.
17. Brittany; transparent, rhombic octahedrons; blonde	68	"
18. Kimito, Finland; rhombic octahedrons; transparent; clear blonde	67—68	"
19. Finland; crystals silvery; grayish-green	67—68	"
20. Aberdeen; transparent; blonde	68	"
21. Josephs-Alpe, Austria; G.=2·713	69 10	Grailich
22. Cape Gozaz, Brazil; pinchbeck-brown	69 25	"
23. Middletown, Ct.; colorless; G.=2·852	70	"
24. Katherinenburg; rhombic prisms in feldspar; transparent; nearly blonde	69—70	Sen.
25. Loc. ——?; colorless; but affords { a central region	70	"
{ an outer region	60	"
26. Nulluk, Greenland	70 36	Grailich
27. Presburg, Hungary	70 40	"
28. Kassigiengoyt, Greenland; green	71	"
29. Kakunda, Brazil; pinchbeck-brown	71 25	"
30. Cam, Bohemia; blonde	71 40	"
31. Minas Geraes, Brazil; pale green	71 50	"
32. ib. ib.; pale brown	72 20	"
33. Hörlberg, Bavaria; pinchbeck-brown	72 25	"
34. Chesterfield, Mass.; G.=2·827; greenish-yellow	72 30—73 30	"
35. Serra de Conceiçao, Brazil	74	"
36. Galmeikirchen, Upper Austria; gray	74 36	"
37. Miask, Ural; pinchbeck-brown	75 25	"
38. Siberia; gray or colorless; G.=2·302	75—76	"

	Appar. Angle.	
39. Chesterfield, Mass., rose	75°	Grailich
40 Goshen ?, Mass., rose-colored	76 10—76 40	"
41 Presburg, Hungary	76 12	"
42. Alençon; hexag.; transparent; grayish-blonde	76—77	Sen.

(2) *Optical axes in the diametral plane of the shorter diagonal.*

43. Saxony; hexag.; silvery, clear gray; transp., macled	44	Sen.
44. Kollin, Prussia; gray, in granite	50 12	Grailich
45. Zinnwald and Schlaggenwald; in granite. Lepidolite?	51 50	"
46. Tyrol; in granite, gray	52 12	"
47. Siberia; colorless	60 30	Sen.
48. Piedmont; rhombic; silvery reflection; grayish-green by trp.	63	"
49. St Feréole, near Brive; transparent; olive-green	65	"
50. Milan; hexag.; greenish-white; silvery; unctuous. not elastic	65	"
51. Fossum, Norway; hexag.; clear olive-green	66	"
52. Scotland; brown; in large thick crystals	68	"
53. Tarascon (Ariége); rhombic; transparent; colorless	69	"
54. Ural, in graphic granite; silvery lustre; color blonde	72	"
55. Utö; rhombs; lustre silvery; yellowish-blonde	72—73	"

* Haughton found for the mica of Dublin Co., Ireland, 53° 8′; of Glenmalure 67° 11′; of Glendalough valley, 70° 4′; of Mt. Leinster, 72° 18′; of Lough Dan, 70°.

On examining different micas pressed between two plates of glass; and subjecting them to changes of temperature, Senarmont found no perceptible change in the optical axes.

Grailich shows that, with slight exceptions, the angle increases with the specific gravity in the mica of a given locality. Thus seven micas from Presburg, Hungary, gave the following:

Specific gravity	2·714	2·735	2·755	2·782	2·790	2·793	2·796
Angle	69·7	70·0	70·5	71·2	72·3	72·4	72·0

Muscovite was so named by the author in 1850, from *Vitrum Muscoviticum* or *Muscovy-glass*, formerly a popular name of the mineral. *Fuchsite* was named after the chemist, Fuchs.

Talcite of Thomson (l. c.), from Wicklow, Ireland, is nothing but margarodite, according to Greg and Lettsom (Min., 203), who say that it invests crystals of andalusite. Thomson, as his description implies, considered the andalusite prisms and investing mica all one mineral—the talcite; and in view of this, the analyses need not here be cited Thomson's *nacrite*, from "Brunswick, Me.," is the green mica of Unity, Me.

Alt.—Mica at times becomes hydrated, losing its elasticity and transparency, and often some portion of the potash; and at the same time it may take up magnesia, lime, or soda The occurrence of water, magnesia, lime, and soda in some micas, especially the margarodites, has been attributed to incipient alteration. See analyses under A, 1, and A, 2.

These changes may be promoted by waters containing carbonates of these bases. R. Blum (Jahrb. Min., 1865, 269) gives the following analysis by Dr. Wolkenhaar of an altered mica (biotite ?) from the dioryte of Schemnitz, which had lost nearly all its alumina and consisted largely of carbonates: $\ddot{\text{Si}}$ 33·34, $\overline{\dddot{\text{Al}}}$ 3·53, $\dot{\text{Fe}}$ 16·01, $\dot{\text{Mn}}$ 0·89, $\dot{\text{Mg}}$ 2·06, $\dot{\text{Ca}}$ 21·73, $\dot{\text{Na}}$ 2·26, $\dot{\text{K}}$ 0·66, $\ddot{\text{C}}$ 20·06=100·44. The carbonic acid would require the $\dot{\text{Ca}}$ 21·73, and $\dot{\text{Mg}}$ 2·06, with $\dot{\text{Fe}}$ 1·22, making 45 p. c. of carbonates. Mica occurs altered to *steatite* and *serpentine*, and Tschermak mentions cases of alteration to amphibole and stilpnosiderite.

294. LEPIDOLITE. Violetfarbigen Zeolith (fr. Rozena) *v. Born*, Crell's Ann., ii. 196, 1791. Lilalith (ib.) *v. Born*. Schuppenstein *Germ.* Lepidolith *Klapr.*, Schrift. Ges. Berl., xi. 59, 1794, Bergm. J., ii. 80, 1792, Beitr., i. 21, 279, 1795, ii. 191. Lepidolite *Kirw.*, i. 208, 1794. Lithionglimmer *C. Gmelin*, Gilb. Ann., lxiv. 371, 1820. Lithia Mica. Lithionit *v. Kob.*, Taf, 54, 1853. Rabenglimmer, Siderischer Fels-Glimmer (fr. Altenberg), *Breith.*, Char., 1823, 1832, Handb., 404, 1841. Zinnwaldit *Haid.*, Handb., 521, 1845.

Orthorhombic. $I \wedge I = 120°$. Forms like those of muscovite. Cleavage: basal, highly eminent. Also massive scaly-granular, coarse or fine. H.=2·5—4. G.=2·84—3. Lustre pearly. Color rose-red, violet-gray or lilac, yellowish, grayish-white, white. Translucent. Optic-axial angle 70°—78°; sometimes 45°—60°.

Comp.—O. ratio for bases and silica mostly 1 : 1½; for Ṙ, R̶, between 1 : 3 and 1 : 4½. The protoxyds (Ṙ) include, besides potash, lithia, rubidia, and cæsia; and in the Zinnwald mica, thallium has been detected. Fluorine is present, and the ratio to oxygen mostly 1 : 12, as in the Rosena, as analyzed by Rammelsberg; other ratios obtained are: in the Ural, Chursdorf, Uto, and Rosena micas, 1 : 20; in the Altenberg (Stein), 1 : 60; in the Zinnwald, 1 : 14, 1 : 11, 1 : 12; in the Juschakova, 1 : 8; in Turner's Altenberg, 1 : 25. But there is much uncertainty connected with all the determinations of the fluorine.

The O. ratio for the bases and silica 1 : 1½ corresponds to a combination of 1 unisilicate to 2 of bisilicate, or the formula $(\dot{R}^3, \bar{R})^2\ddot{S}^3 + 2(\dot{R}^3, \bar{R})\ddot{Si}^3$; and also to simply a unisilicate with accessory silica $(\dot{R}^3, \bar{R})^2\ddot{Si}^3 + 2\ddot{Si}$.

Analyses: 1, Klaproth (Beitr., i., ii., v.); 2, Gmelin (l. c.); 3, Kralovanski (Schw. J., liv. 280); 4, Rammelsberg (5th Suppl., 120); 5, Regnault (Ann. d. M., III. xiii. 151); 6, 7, Gmelin; 8, Turner (Edinb. J. Sci., iii., vi. 61); 9, Klaproth; 10, Lohmeyer (Pogg., lxi. 377); 11, Stein (Ramm. 5th Suppl., 119); 12, Rammelsberg (ib.); 13–16, Turner (l. c.); 17, 18, Rosales (Pogg., lviii. 154); 19, Turner (l. c.); 20, Stein (J. pr. Ch., xxviii. 295):

[a] 6·80 Fe O included.

In a recent analysis of the Rosena lepidolite, made since the discovery of the metals rubidium and cæsium, Cooper obtained (Pogg., cxiii. 348):

S̈i	A̶l	F̶e	Ṁg	Ċa	Ṙb	Ċs	L̇i	LiF	NaF	KF	Ḣ
50·32	28·54	0·73	0·51	1·01	0·24	*tr.*	0·70	0·99	1·77	12·06	3·12=99·99

The proportion of fluorine was determined by the loss. Reckoning the fluorine as oxygen, the O. ratio for Ṙ, R̶, S̈i is 1 : 4·25 : 8·43. O. D. Allen (Am. J. Sci., II. xxxiv. 369) found in the Hebron lepidolite cæsium 0·3, and rubidium 0·14; and later (p. 373) 0·3 of rubidium nearly.

Rammelsberg's analysis of the Zinnwald lepidolite (anal. 12) gave him the O. ratio 1·15 : 3 : 6·2, or nearly 1 : 3 : 6; and that of the Rozena (anal. 4) 1 : 4·4 : 9·13, or approximately 1 : 4½ : 9, but for which he proposes 1 : 4½ : 7½, since the specimen he analyzed contained free quartz in visible grains, and his silica might consequently have been too high [the ratio 1 : 1½ between the bases and silica would require 1 : 4½ : 8¼]. From Rosales's analysis of the Juschakova (anal. 17), he deduces the ratio 1 : 2·8 : 6·4, or approximately, as he observes, 1 : 3 : 6.

Anal. 11 is cited by Breithaupt for his *rabenglimmer;* G.=3·146—3·190; color greenish-black to dark green.

The Zinnwald mica has been called *zinnwaldite.*

More chemical investigations are required before the species lepidolite can be correctly subdivided or comprehended. Physically it is hardly distinct from muscovite.

Pyr., etc.—In the closed tube gives water and reaction for fluorine. B.B. fuses with intumescence at 2—2·5 to a white or grayish glass, sometimes magnetic, coloring the flame purplish-red at the moment of fusion (lithia). With the fluxes some varieties give reactions for iron and manganese. Attacked but not completely decomposed by acids. After fusion, gelatinizes with muriatic acid.

Obs.—Occurs in granite and gneiss, especially in granitic veins, and is associated sometimes with cassiterite, red, green, or black tourmaline, amblygonite, etc. Found near Utö in Sweden; grayish-white at Zinnwald in Bohemia; at Altenberg, Chursdorf, and Penig in Saxony; Juschakova in the Ural; lilac or reddish-violet at Rozena in Moravia; near Chanteloube, Dept. Haute Vienne France; at Campo on Elba; brown at St. Michael's Mount in Cornwall; Argyll in Scotland; Tyrone in Ireland.

In the United States, a granular and a broad foliated variety at Paris, and also at Hebron, Me., with red tourmaline and amblygonite; granular near Middletown, Conn. The rose mica of Goshen, Mass., is muscovite.

The optical axes lie in the plane of the longer diagonal in the following lepidolites; the angles of divergence observed are as follows:

Paris, Me.; whitish-green; with green tourmaline	74°—74° 30′	Silliman.
" rose-colored	74	Grailich.
Siberia	75 40	"
Rozena, Moravia	76	"
Penig, Saxony	76 30	"

A "lepidolite" from Bournon's collection gave Senarmont 55°; and a Zinnwald mica, silvery or greenish-blonde, 46°—47°. Grailich made the angle of mica from Zinnwald and Schlaggenwald 51° 10′. Each of these varieties, giving comparatively small angles, have the plane of the axes *brachydiagonal;* and the small angle may arise from an interlamination of a brachydiagonal kind with a macrodiagonal.

Named lepidolite from λεπίς, *scale*, after the earlier German name *Schuppenstein*, alluding to the scaly structure of the massive variety of Rozena.

295A. SNARUMITE *Breith.* (B. H. Ztg., xxiv. 364, 1865). A mica-like cleavage in one direction, and another transverse imperfect. Occurs massive and in tufts columnar in structure, with H.=4—5·5, the least on cleavage-surface; G.=2·826; lustre on cleavage-face pearly, elsewhere vitreous; color mostly reddish-white, colorless, grayish-white. It is, according to Richter (l. c.), a silicate of alumina, lithia, soda, and potash. Comes from the shore of the Snarum-Elf, near Snarum, in Norway.

296. CRYOPHYLLITE. *J. P. Cooke*, Am. J. Sci., II. xliii. 217, 1867.

Orthorhombic. $I \wedge I = 120°$. In six-sided prisms. Cleavage: basal highly eminent, as in the Mica group. Twins: composition-face *i-ĭ*. Also massive, an aggregate of scales.

H.=2—2·5. G.=2·909. Lustre of cleavage-face bright pearly inclining to resinous. Color by transmitted light dull emerald-green, transverse to axis brownish-red. Streak grayish, slightly greenish. Thin folia tough and elastic. Optic-axial angle 55° to 60°; plane of axes brachydiagonal; Cooke.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$=3 : 4 : 14; for $\dot{\mathrm{R}}+\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, 1 : 2; whence the formula $(\frac{3}{7}\dot{\mathrm{R}}^3+\frac{4}{7}\overline{\mathrm{R}})\ddot{\mathrm{Si}}^3$, in which $\dot{\mathrm{R}}$=protoxyd of iron, potash, and lithia, with a trace of soda, rubidia, and cæsia. But if the micas are unisilicate in type, the formula may be $(\frac{3}{7}\dot{\mathrm{R}}^3+\frac{4}{7}\overline{\mathrm{R}})^2\ddot{\mathrm{Si}}^3+3\ddot{\mathrm{Si}}$; or else, with half the excess of silica basic. Analysis: Cooke (l. c.):

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\overline{\mathrm{Mn}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{Li}}$	$\dot{\mathrm{Na}}$, $\dot{\mathrm{Rb}}$	SiF^2
$(\frac{2}{3})$	51·49	16·77	1·97	0·34	7·98	0·76	13·15	4·06	tr.	3·42=99·94.

Pyr., etc.—In the flame of a candle fuses easily; and B.B., with some intumescence to a grayish enamel (F.=1·5—2), giving the flame a lithia reaction. In fine powder decomposed by the dilute mineral acids, the silica separating as a powder. The fluorine is not expelled even at a red heat.

Obs.—Occurs in the granite of Cape Ann, with danalite and lepidomelane (annite).

SCAPOLITE GROUP.

A list of the species of the Scapolite group, with their oxygen ratios and formulas, and the ratios of the non-alkaline to the alkaline protoxyd bases, is given on page 252. Although the oxygen ratios vary from 1:1:2, 1:2:3, 1:3:4, to 1:2:4 and 1:2:6½, the species are closely *alike* in the square-prismatic forms of their crystals, in the small number and the kinds of occurring planes, and in the angles. The variation in the basal angle of the fundamental octahedron (1 : 1) for the species of the group is less than 40′, the extremes being 64° 13′ (sarcolite) and 63° 40′ (meionite). The species are white or grayish-white in color, except when impure, and then rarely of dark color; the hardness 5—6·5; G.=2·5—2·8 (2·932? in sarcolite). The alkali present, when any, is soda, with only traces of potash.

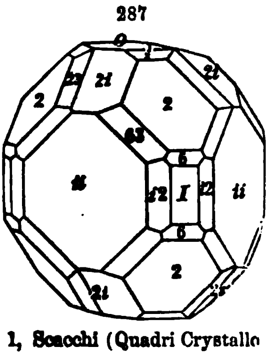
Meionite was the first species of the Scapolite group distinctly recognized. It is, however, probable that scapolite was included with lamellar pyroxene under the name of *White Schörl-Spar* (Skörlspat) by Cronstedt, who mentions Pargas, in Finland, as one of its localities. The names *Wernerite* and *Scapolite* were both introduced by d'Andrada (of Portugal) in the same article (Scherer's J., iv. 35, 38, 1800), and applied to specimens from the same region in Norway Wernerite is the *first* of the two in the article. Haüy used the names *Wernerite* and *Scapolite* (supposing the species distinct) in his Traité of 1801. But in his Mineralogical Course for 1804 or 1805 arbitrarily set aside the latter for *Paranthine*. Monteiro, a friend of d'Andrada, and speaking in his behalf, protested in 1809 (J. de Phys., lxviii. 177) against the change, and after arguing that wernerite and scapolite were identical, both on chemical and crystallographic grounds, urged the adoption of the name *Wernerite* for the species. In the following pages the name Scapolite is retained for the group, so that the minerals may all be called *scapolites*, as those of the feldspar group are called feldspars, and those of the mica and chlorite groups, respectively micas and chlorites; and the name Wernerite is applied to the most prominent division of the old species. This course meets satisfactorily the question of priority, and also the convenience of the science.

296. SARCOLITE. Sarcolite *Dr. Thompson* (of Naples), 1807. [Not Sarcolite du Vicentin (= Gmelinite) *Faujas*, *Vauq.*, Ann. d. Mus., ix. 249, 1807, xi. 42.] Analcime carnea *Mont. & Cov.*, Min. Vesuv., 1825.

Tetragonal; $O \wedge 1\text{-}i = 156°\ 5'$; $a = 0{\cdot}4435$. Observed planes as in the annexed figure; hemihedral in the planes 2-3, only the alternate occurring. $O \wedge 2 = 128°\ 33'$, $2 \wedge 2$, pyr., 132° 52, $O \wedge \frac{3}{8} = 157°\ 19'$, $I \wedge 2 = 141°\ 27'$; $I \wedge 6 = 104°\ 52\frac{1}{2}'$; $1 \wedge 1$ (not occurring planes), bas.,=64° 13′. Crystals small.

H.=6. G.=2·545, Brooke; 2·932, Rammelsberg. Lustre vitreous. Color flesh-red to rose-red, reddish-white. Transparent to subtransparent. Extremely brittle.

287



Comp.—O. ratio for $\dot{R}, \bar{R}, \dddot{S}i = 1:1:2$; $(\frac{1}{3}(\frac{9}{10}\dot{C}a + \frac{1}{10}\dot{N}a)^3 + \frac{1}{3}\bar{A}l)^2 \dddot{S}i^3$ = Silica 39·7, alumina 22·8, lime 33·4, soda 4·1=100. Analyses: 1, Scacchi (Quadri Crystallographici, Naples, 66, 1842); 2, Rammelsberg (Pogg., cix. 570):

1.	$\ddot{S}i$ 42·11	$\bar{A}l$ 24·50	$\dot{C}a$ 32·43	$\dot{N}a$ 2·93=101·97 Scacchi.	
2.	(⅓) 40·51	21·54	32·36	3·30, $\dot{K}$ 1·20=98·91 Ramm.	

corresponding nearly to the composition of idocrase.

Pyr., etc.—B.B. fuses to a white enamel. With acids gelatinizes.

Obs.—Of rare occurrence at Mt. Somma.

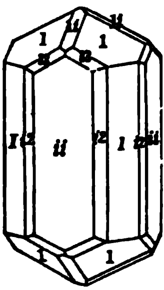
Named from σάρξ, *flesh*, and λίθος, *stone*, in allusion to the color.

The crystallization was first correctly ascertained by Brooke (Ed. J. Sci., i. 189, 1824). Haüy had pronounced it cubic (Tr., iii. 1822). Kokscharof found $O \wedge 2=128° 38'$, and $O \wedge 2\text{-}i=138° 30'$ (Min. Russl., ii. 110). Rammelsberg gives (l. c.) $O \wedge 2=128° 45'$, and $O \wedge 2\text{-}i=138° 27'$. The above figure is from Hessenberg (Min. Not., No. I.). The plane usually made 1 is here made 2, in order that the lettering of the crystals may correspond with that of the crystals of other species of the Scapolite group.

297 MEIONITE.

Hyacinte blanche de la Somma *de Lisle*, Crist., ii. 289, 290, Pl. iv. f. 118, 1783. Meionite *H.*, Tr., ii. 1801.

288



Tetragonal: $O \wedge 1\text{-}i = 156° 18'$; $a=0·439$. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}3$, $i\text{-}2$; pyramids, 1, $1\text{-}i$; zirconoids, 1-3, 3-3; sometimes hemihedral in the planes 3-3, the alternate being wanting. $O \wedge 1=148° 10'$, $1 \wedge 1$, pyr.,$=136° 11'$, basal 63° 40'. Cleavage: $i\text{-}i$ and I rather perfect, but often interrupted.

H.=5·5—6. G.=2·6—2·74; 2·734—2·737, fr. Somma, v. Rath. Lustre vitreous. Colorless to white. Transparent to translucent; often much cracked within.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{S}i=1:2:3$; $(\frac{1}{3}(\frac{11}{12}\dot{C}a+\frac{1}{12}\dot{N}a)^3+\frac{2}{3}\bar{A}l)^2\ddot{S}i^3$=Silica 41·6, alumina 31·7, lime 24·1, soda 2·6=100. Analyses: 1, L. Gmelin (Schw. J., xxv. 36, xxxv. 348); 2, Stromeyer (Unters., 378); 3, Wolff (De Comp. Ekeberg., etc., Ramm., 2d Suppl., 133); 4, v. Rath (De Comp. Wern., Pogg., xc. 87); 5, Damour (L'Institut, 1862, 21):

		$\ddot{S}i$	$\bar{A}l$	$\bar{F}e$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	
1.	Somma	40·8	30·6	1·0	——	22·1	2·4	——,	$\ddot{C}$ and ign. 3·1=100 Gmelin.
2.	"	40·53	32·73	——	——	24·24	1·81		$\dot{F}e$ 0·18=99·50 Stromeyer.
3.	"	42·07	31·71	——	——	22·43	0·45	0·31,	ign. 0·31=97·29 Wolff.
4.	"	42·55	30·89	0·41	0·83	21·41	1·25	0·93,	" 0·19=98·46 Rath.
5.	"	41·80	30·40	——	0·46	19·00	2·51	0·86,	" 3·17, gangue 0·46=98·66 Dam.

An opaque meionite examined by Gmelin having G.=2·65, lost 1·6 by ignition, and afforded some carbonic acid, it containing carbonate of lime.

Pyr., etc.—B.B. fuses with intumescence at 3 to a white blebby glass. Decomposed by acid without gelatinizing (v. Rath). Gmelin states it to be fusible with difficulty on the edges, and both Gmelin and v. Kobell state that it gelatinizes with muriatic acid. An examination of a specimen received from Scacchi fully confirms vom Rath's conclusions.

Obs.—Occurs in small crystals in geodes, usually in limestone blocks, on Monte Somma, near Naples.

Rammelsberg obtained (Pogg., xciv. 434) for $1 \wedge 1$, basal, 63° 48'; over summit, 116° 12'; $1 \wedge 1$, pyr.,$=136° 12'$; the former gives $O \wedge 1=148° 6'$, and $1 \wedge 1$, pyr., 136° 8'. Kokscharof found $1 \wedge 1$, pyr.,$=136° 10'—136° 11\frac{1}{2}'$ (Min. Russl., ii. 105); Scacchi, 136° 11' (l. c.); vom Rath, for crystals from L. Laach, 135° 58½ (Pogg., cxix. 262), giving $a=0·442$.

Named by Haüy from μείων, *less*, the pyramid being less acute than in idocrase.

298. PARANTHITE.

Paranthine pt. Skapolit, Scapolit, pt. Wernerit pt. Skapolit (fr. Storgord in Pargas) *N. Nordenskiöld*, Schw. J., xxxi. 417, 1821; id. (fr. Tunaberg) *Walmstedt* His. Min. Geog. ueb. Wöhler, 98, 1826.

Tetragonal. Forms like those of wernerite; difference in angle, if any, undetermined. Observed planes: prismatic, *I*, *i-i*; octahedral, 1, 1-*i*, zirconoid, 3-3, Nord. Fig. 288, excepting the planes *i*-2 wanting (form observed at Ersby). Cleavage lateral. Also massive.

H.=5·5. G.=2·736, Pargas, Nordenskiöld; 2·849, Tunaberg, Walmstedt. Lustre between pearly and vitreous; outer surface sometimes a little waxy. Color white, grayish-white, gray, pale grayish-green, sea-green, approaching celandine-green. Translucent.

Comp.—O. ratio for $\dot{R}$, $\overline{R}$, $\ddot{Si}$=1 : 3 : 4; $(\frac{1}{4}\dot{Ca}^3+\frac{3}{4}\overline{Al})^2\ddot{Si}^3$=Silica 43·0, alumina 36·9, lime 20·1=100.

Analyses: 1–3, N. Nordenskiöld (l. c.); 4, Walmstedt (l. c.); 5, Wolff (Comp. Ekeberg. Diss. Berolini, 1843):

	$\ddot{Si}$	$\overline{Al}$	$\overline{Fe}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$	
1. Ersby, *tri. cryst.*	43·83	35·43	—	—	18·96	—	—	1·03	=99·25 Nord.
2. " *cryst.*	43·00	34·48	—	—	18·44	—	—	1·60	=97·52 Nord.
3. Storgard	41·25	33·58	—	0·54	20·36	—	—	3·32	=99·05 Nord.
4. Tunaberg, *cryst.*	43·83	35·28	0·68	—	19·37	—	—	—	=99·06 Walmst.
5. Pargas, Ersby ? *wh. or gnh.*	45·10	32·76	—	0·68	17·84	0·76	—	1·04	=98·18 Wolff.
6 Pargas, *gnh. cryst.*	45·46	30·96	—	—	17·22	2·29	1·31	1·29	=98·53 Rath.

Anal. 1, G.=2·736; 3, G.=2·749; 4, G.=2·849; 5, G.=2·712; 6, G.=2·654.

Anal. 1, 2, 4, correspond to the O. ratio 1 : 3 : 4 (more nearly 1 : 3·1 : 4·3); anal 3, to 1 : 2·6 : 3·6; anal. 4, to 1 : 3 : 4·3; anal. 5, to 1 : 3 : 4·6; each corresponding very nearly to the O. ratio for bases and silica 1 : 1.

An Ersby specimen afforded Hartwall and Hedberg (Jahresb., iv. 155) $\ddot{Si}$ 48·77, $\overline{Al}$ 31·05, $\dot{Ca}$ 15·94, $\dot{Na}$ 3·25, ign. 0·61=99·62; which gives the O. ratio 1·1 : 3 : 5·3, or a considerable excess of silica, with some soda. It is probably the same mineral with that of anal 5, altered.

Pyr., etc.—The Tunaberg crystals B.B. fuse easily with intumescence to a globule.

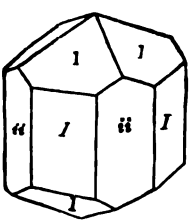
Obs.—Occurs in greenish 4- and 8-sided prisms, some of them terminated, at Tunaberg in Sweden; also at Ersby and Storgard in the parish of Pargas, Finland.

An analysis by Laugier of "Paranthine" from Arendal afforded him (J. de Phys., lxviii. 36, 180, 1809) $\ddot{Si}$ 45·0, $\overline{Al}$ 33·0, $\overline{Fe}$, $\dot{Mg}$ 1·0, $\dot{Ca}$ 17·6, $\dot{Na}$ 1·5, $\dot{K}$ 0·5, which agrees closely with the last analysis by Wolff. The name *paranthine*, substituted for scapolite (and for Arendal specimens) by Haüy, was consequently connected in France, almost as soon as introduced, with the above composition, and continued so to be for nearly 20 years afterward, Berzelius giving the formula $\dot{Ca}^3\ddot{Si}+3\overline{Al}\ddot{Si}$ (and also the name *paranthine*) in his N. Syst. Min., 1819, 216. Although Laugier's analysis of the Arendal scapolites is not confirmed by later analysts, the name *paranthine* may well be retained for this section of the Scapolite group.

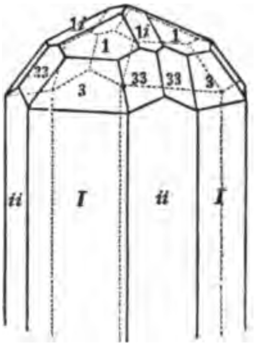
299. **WERNERITE.** Wernerite (fr. Norway) *d'Andrada*, J. de Phys., li. 244, 1800, Scherer's J., iv. 35, 1800. Scapolite (fr. Norway) *d'Andrada*, ib., 246, and ib. 38, 1800. Rapidolith *Abildgaard*, Ann. Ch., xxxii. 195, 1800. Wernerite, Scapolite, *H.*, Tr., iii. iv. 1801. Skapolith, Arcticit [=Wernerite] *Wern.*, 1803, Ludwig's Wern., ii. 210, 1804. Paranthine [=Scapolite of Arendal] *H.*, Lucas Tabl., 205, 1806; H. Comp. Tabl., 45, 1809. Fuscit (fr. Arendal) *Schumacher*, Verzeichn., 104, 1801. Chelmsfordite *J. F. & S. L. Dana*, Outl, Min. G. Boston, 44, 1818 Nuttallite (fr. Bolton) *Brooke*, Ann. Phil., II. vii. 316, 1824. Glaukolith (fr. L. Baikal) *v. Fischer* Sokoloff's Bergwerks J.; John. Chem. Unters., ii. 82, 1810; Glaucolite.

Tetragonal: *O* ∧ 1-*i* = 156° 14½′; *a*=0·4398. Observed planes *O*; vertical, *I*, *i-i*, *i*-2, *i*-3; pyramids, 1, 3; zirconoid, 3-3. 3-3 and *i*-2 often hemihedral, right or left, half of the eight planes being either wanting, or (as in f. 291, a top view) much smaller than the othe half.

289

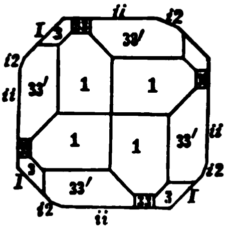


290



R. Slüdianka.

291



Hirwensalo, Finland.

O ∧ 1=148° 6′
I ∧ 1=121 54
I ∧ *i*-2=161 34
I ∧ *i*-3=153 26
i-i ∧ *i*-3=161 34
i-i ∧ *i*-2=155 26
1 ∧ 1, pyr.,=136 7
1 ∧ 1, bas., 63 48
1-*i* ∧ 1-*i*, pyr.,=146 53

Cleavage: *i-i* and *I* rathe distinct, but interrupted. Als massive, granular, or with a faint fibrous appearance; sometimes columnar.

H.=5–6. G.=2·63–2·8. Lustre vitreous to pearly externally, inclining to resinous; cleavage and cross-fracture surface vitreous. Color white, gray, bluish, greenish, and reddish, usually light; streak uncolored. Transparent—faintly subtranslucent. Fracture subconchoidal. Brittle.

Var.—1. *Ordinary.* In crystals, white to gray, grayish-green, brownish, and rarely, from impurity, nearly black. Kokscharof gives for the angles those of meionite, namely, 1 ∧ 1, pyr.,= 136° 11′, bas.,=63° 42′, 1-*i* ∧ 1-*i*, pyr.,=146° 57½′, bas.,=47° 26′, *i-i* ∧ 1-*i*=113° 43′, *I* ∧ 1=121° 51′ (Min. Russl., ii. 82). The prisms are sometimes several inches thick.

Nuttalite (named after T. Nuttal) is white to smoky brown scapolite from Bolton, Mass. Chemists have found wide variations in composition, and have shown that it is sometimes much altered The crystals and massive variety of Chelmsford, Mass., of gray, greenish, and reddish shades of color, has been called *Chelmsfordite.*

2. *Massive.* *Glaucolite* is of pale violet-blue, bluish, indigo-blue, to greenish-gray colors, sometimes resembling cancrinite, but having the cleavage of scapolite. It is from near R. Slüdianka, beyond L. Baikal, Siberia, where it occurs in veins in granite. The pink scapolite of Bolton is similar. Named from γλαυκός, *greenish-gray* or *sea-green.*

Comp.—O. ratio for $\dot{R}$, $\dddot{R}$, $\ddot{Si}$=1 : 2 : 4; or for bases and silica 1 : 1⅓. Formula $(\frac{1}{3}(\dot{C}a, \dot{N}a)^3 + \frac{2}{3}\dddot{A}l)^2 \ddot{S}i^3 + \ddot{S}i$; or else with half the excess of silica ($\ddot{S}i$) basic; =, if $\dot{C}a$: $\dot{N}a$=4 : 1, Silica 48·4, alumina 28·5, lime 18·1, soda 5·0=100.

The above is the mean ratio; but the analyses show variations from it, as seen below, due, in part at least, to impurities, alteration, or incorrect determinations.

Analyses: 1, 2, G. v. Rath (Pogg., xc. 82, 288); 3, Thomson (Min., i. 273); 4, Wolff (Inaug Diss. Berlin. 1843, Ramm. Min. Ch., 719); 5, Wurtz (Am. J. Sci., II. x. 325); 6–8, G. v. Rath (l. c.); 9, Berg (Jahresb., xxv. 356); 10, v. Rath (l. c.); 11, Wolff (l. c.):

Anal. 1, G.=2·788, blackish-green crystals, the interior in part opaque; 2, 2·748, and like the preceding in color; 3, 2·709; 4, G.=2·718; 5, G.=2·704; 6, G.=2·751; 7, G.=2·697; 8, G.=2·763; 9, G.=2·34 ?, from the parish of Drothems in E. Gothland; 10, G.=2·666; 11, G.=2·738, color blackish-green and greenish-gray.

The oxygen ratios for $\dot{R}$, $\dddot{\bar{R}}$, $\ddot{S}i$, corresponding to the analyses are:

1. 1 : 2 : 3·6
2. 1·2 : 2 : 4·1
3. 1 : 2 : 4
4. 1 : 2·2 : 4·3
5. 1 : 1·8 : 3·7
6. 1 : 1·7 : 3·4
7. 1 : 1·8 : 3·6
8. 1 : 1·7 : 4·0
9. 1·1 : 2·0 : 4·0
10. 1 : 2·1 : 4·0
11. 1·1 : 2 : 4·0

The first two analyses by v. Rath of specimens named *nuttallite*, and attributed to Bolton, are evidently of altered crystals, as the presence of over 3 p. c. of oxyd of iron indicates. The color stated, "blackish-green," is further evidence on this point. Moreover it is a very unusual color at the locality, as nuttallite is ordinarily white, grayish-white, and pale smoky brown, the darker color occurring sometimes in crystals that are partly whitish. V. Rath states that the mineral was very difficultly fusible. Thomson's analysis (No. 3) was also made on an altered specimen, as it gave 5 p. c. of water.

Muir, in an analysis of nuttallite published by Thomson (Min., 383) obtained $\ddot{S}i$ 37·81, $\dddot{A}l$ 25·10, $\dddot{F}e$ 7·89, $\dot{C}a$ 18·34, $\dot{K}$ 7·30, $\dot{H}$ 1·50=97·94. The potash and the low silica, as well as the iron, indicate an altered specimen, if the analysis may be so far trusted as to draw a conclusion from it. The color of the mineral (white, to yellowish, bluish, or greenish) and the associated minerals on the specimen (sphene and green pyroxene) show that Muir probably had true nuttallite for investigation.

Wurtz's analysis of the pink scapolite of Bolton gives more soda than the rest. In a recent trial (priv. contrib.) B. S. Burton found about 3 p. c. of alkalies, sustaining Wolff's results.

The bluish-gray massive variety from Malsjö has been analyzed also by Suckow (Verwitt. Min., 138), but as he fonnd no alkalies, his results are questionable, either on the ground of the specimen or the analysis. He obtained $\ddot{S}i$ 48·17, $\dddot{A}l$ 28·27, $\dddot{F}e$ 2·38, $\dot{C}a$ 19·04, $\dot{H}$ 2·00=99·86. Suckow analyzed also a kaolin from Malsjö, a result of alteration of the scapolite (see p. 323).

Pyr., etc.—B.B. fuses easily with intumescence to a white blebby glass. Imperfectly decomposed by muriatic acid.

Obs.—Occurs in metamorphic rocks, and most abundantly in granular limestone near its junction with the associated granitic or allied rock; sometimes in beds of magnetite accompanying limestone. It is often associated with light-colored pyroxene, amphibole, garnet, and also with apatite, sphene, zircon; amphibole is a less common associate than pyroxene. The scapolite of Pargas, Finland, is in limestone; that of Arendal in Norway, and Malsjö in Wermland, occurs with magnetite in limestone.

Some foreign localities of the mineral are above indicated. In the following those of wernerite and ekebergite are not yet distinguished. In *Vermont*, at Marlboro', massive. In *Mass.*, at Bolton and Boxborough, in crystals, sometimes large; at Chelmsford; Littleton; Chester; Carlisle; Westfield, massive; at Parsonsfield and Raymond, near Dr. Swett's house, crystals, with yellow garnet. In *Conn.*, at Monroe, white and nearly fibrous; a stone quarry at Paugatuck, Stonington, massive. In *N. York*, at Two Ponds in Orange Co., reddish-white crystals with pyroxene, sphene, and zircon, one crystal 10 in. long and 5 in diameter; at Fall Hill, Monroe, of white and bluish colors, massive, with lamellar pyroxene; in Warwick of the same county, near Amity, milk-white crystals with pyroxene, sphene, and graphite; 5 m. S. of Warwick, and 2 m. N. of Edenville, near Greenwood Furnace (planes 1, *I*, *i*-2, *i*-*i*), are other good localities; in Essex Co., perfect crystals and massive nearly fibrous, white and greenish-white, abundant near Kirby's graphite mine, 4 m. N. E. of Alexandria, in Ticonderoga, associated with pyroxene; at Crown Point; in Lewis Co., in fine crystals, white, bluish, and dark gray, presenting the play of light not unusual with this variety; edges of the crystals often rounded. In *N. Jersey*, at Franklin and Newton, and 3 m. W. of Attleboro', crystallized, in limestone. In *Canada*, at G. Calumet Id., massive lilac-colored; at Hunterstown, in large crystals, with sphene; at Grenville, with pyroxene.

Pisani has analyzed a scapolite from Brakke, Norway, which gives a composition between that of paranthite and wernerite. He obtained (C. R., lv. 450):

$$\ddot{S}i\ 48·78 \quad \dddot{A}l\ 32·65 \quad \dddot{F}e\ 0·87 \quad \dot{M}g\ 1·15 \quad \dot{C}a\ 13·32 \quad \dot{N}a\ 2·59 \quad \dot{K}\ 0·63 \quad \dot{H}\ 1·30=101·29.$$

It had been called Esmarkite.

One of the minerals called *saussurite* by Boulanger, stated to come from Mt. Genèvre, gave him G.=2·65, and the composition $\ddot{S}i$ 44·6, $\dddot{A}l$ 30·4, $\dot{M}g$ 2·5, $\dot{C}a$ 15·5, $\dot{N}a$ 7·5 (Ann. d. M., III. viii. 159). It is stated to be greenish-white and compact, and to occur associated with a greenish-brown smaragdite. In low specific gravity it is near scapolite. But we may suspect that there is some mistake about the specific gravity, in which case it may be zoisite (see p. 290) like other saussurite of the Alps. It agrees rather nearly with the latter in composition.

Canaanite, a grayish-white or bluish white rock occurring with dolomite in Canaan, Conn., and referred to massive scapolite by some authors, is massive whitish pyroxene, a mineral common in crystals in the dolomite of the region.

A so-called *glaucolite* from the L. Baikal region, analyzed by Bergemann (Pogg., lx. 267) and Givartovski (Bull. Soc. Nat. Moscow, 1848, 548) differs from the true glaucolite in being difficultly fusible (as much so as orthoclase), and also in composition, these analysts obtaining:

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	50·58	27·60	0·10	0·85	3·73	10·26	2·96	1·26	1·73=99·07 Bergemann.
2.	50·49	28·12	0·44	0·59	2·68	11·31	3·10	1·00	1·78=99·51 Givartovski.

It was massive, of a greenish-blue color, with G.=2·721, Berg.; 2·65, Giv. It has been supposed to be a feldspar.

Alt.—As the altered scapolites that have been derived from ekebergite or paranthite have not been distinguished from those derived from wernerite, the following observations are made to include all:

In the alteration of the scapolites, one or more of the following changes occur, as illustrated in the following analyses of different kinds:

1. The hydration of the mineral.

2. The loss of part or all of the protoxyd bases, often effected largely through the action of carbonated waters carrying off the lime as carbonate.

3. The substitution of potash for the soda or lime, due to the action of the carbonates in solution in percolating waters.

4. The increase in the amount of soda, probably by the action of carbonate of soda or chlorid of sodium in solution.

5. The introduction of oxyd of iron, through salts of lime (organic, bicarbonate, etc.) in solution.

6. The substitution of magnesia for other protoxyd bases.

7. The loss of silica as well as protoxyd bases.

By the substitution of potash, the mineral passes either to the state of *pinite* (anal. 8 to 15), or to that of a *potash mica* (anal. 15, 16). By the acquisition of iron (anal. 17, 18) it passes in some cases to *epidote* (anal. 19). By the introduction of magnesia, it may pass to *steatite*; or of magnesia and potash, to a *magnesia mica* (anal. 20). By a loss of bases, the proportion of silica left increases (anal. 4, 5, 6, 21, 22, 23); and by a loss of silica also (which may become opal in its separation), the mineral passes to a *kaolin*-like compound, a common result of its alteration (anal. 24). Moreover, silica may remain, and the altered crystal become by additions a siliceous pseudomorph, as occurs at Pargas.

Analyses: I. *Hydrous.* 1, Weibye and Berlin (Pogg., lxxix. 302).

II. *Containing carbonate of lime.* 2–6, Hermann (J. pr. Ch., xxxiv. 177); 7, Brewer (This Min., 1850, 680); 7*a*, same, with the $\ddot{\mathrm{C}}$ removed.

III. *Potassic and often also carbonated.* 8, v. Rath (Pogg., xc. 288); 8*a*, same, with the $\ddot{\mathrm{C}}$ removed; 9, T. S. Hunt (Rep. G. Can., 1852–53, 168, 1863, 474); 10, Stadtmüller (Am. J. Sci., II. viii. 394); 11, T. S. Hunt (ib., 103); 12, Crossley (This Min., 1850, 680); 13, J. D. Whitney (Am. J. Sci., II. xvi. 207); 14, T. S. Hunt (Rep. G. Can., 1853, 1863); 15, Bischof (Ch. Geol., ii. 1433); 16–19, v. Rath (l. c.); 20, Bischof (l. c.); 21, John (Beud. Min., ii. 94, 1832); 22, Berzelius (Afh. i. Fys., ii. 202); 23, Hartwall & Hedberg (Jahresb., iv. 155); 24, Suckow (Verwitt. Min., 138 1848):

[a] With a little $\mathrm{Fe}^2\mathrm{O}^3$. [b] Probably too high.

The following are the characters of different altered scapolites, including those of which analyses are above given:

ATHERIASTITE *Weibye* (Pogg., lxxix. 302, 1850). Anal. 1. Like scapolite in form; color greenish; opaque. From Arendal, with black garnet and keilhauite.

STROGANOVITE *Herm.* (J. pr. Ch., xxxiv. 178, 1845) (Anal. 2). Has the form of scapolite (Koksch. Min. Russl., iii. 95). Color yellowish to light oil-green; lustre greasy; translucent; H.=5·5, G.=2·79. B.B. fuses easily with intumescence. From the Slüdianka in Dauria. The analysis afforded 6·4 p. c. of carbonic acid, which is above removed; this corresponds to 11·4 p. c. of $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$.

Anal. 3. Large gray crystals, containing 9·23 p. c. of $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$; G.=2·74. In the anal. as above given, 4·06 of $\ddot{\mathrm{C}}$ is removed. Occurs at Diana, N. Y., with sphene in calcite.

Anal. 4. White crystals with calcite, from Bolton; G.=2·66. In the anal. as above given, 2·5 p. c. of $\ddot{\mathrm{C}}$ is removed. Anal. 5, reddish massive, from Bolton; G.=2·70. Anal. 8, massive, yellowish; H.=4·5; G.=2·787. Contains 7·80 p. c. of $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$. From Bolton.

Anal. 6. Whitish massive, from Gulsjö; contains 3·41 $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$; G.=2·69. In the anal. above, 1·5 p. c. of $\ddot{\mathrm{C}}$ removed.

Anal. 7. Greenish or yellowish-green, cleavable, and partly in crystals, from Franklin, N. J., having H.=3·5, G.=2·78, with subresinous lustre; B.B. very fusible. Contains 10·72 p. c. of $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$.

Anal. 9. Greenish-gray, waxy in lustre to pearly, subtranslucent, with H.=5·5, G.=2·640--2·667; from Perth in Canada. Contains considerable magnesia as well as potash.

Anal. 10. In grayish crystals, from Diana, associated with sphene. (Not from Bolton, as announced; the specimen shows by its character and the associated minerals that it is unquestionably from Diana.)

ALGERITE *Hunt* (Am. J. Sci., II. viii. 103, 1849) (anal. 11—13) occurs in slender square prisms, sometimes 2 or 3 in. long, imbedded in calcite. Yellowish to gray and usually dull. Brittle. H. =3—3·5; some crystals more altered, 2·5. G.=2·697—2·712, Hunt; 2·78, Crossley. From Franklin, Sussex Co., N. J. The varying results of analyses, and the presence of carbonate of lime, of magnesia, and the relations to known examples of altered scapolite, confirm the view derived from the form and appearances, that algerite is an altered scapolite, and related to *pinite*.

WILSONITE *Hunt* (Logan's Rep. Can., 1853 and 1863, Am. J. Sci., II. xix. 428) (anal. 14) is a massive mineral from Bathurst, Canada, affording square prisms by cleavage, and having H. =3·5, G.=2·765—2·776, lustre vitreous, a little pearly on cleavage surfaces; color reddish-white, rose-red, and peach-blossom red. According to Chapman (Am. J. Sci., II. xx. 269), its crystallization and other characters are essentially those of scapolite. It is associated with apatite, calcite, and pyroxene. The oblique basal cleavage, mentioned by Hunt, is, as stated in the last edition of this work, p. 503, only a fracture. Hunt in Rep. G. Can. 1863 makes it a variety of gieseckite. Occurs also in northern N. York. See further under PINITE, p. 479.

Terenite of Emmons (Rep. G. N. Y., 1837, 152) has the form of scapolite, with H.=2; G.=2·53; lustre a little pearly; color yellowish-white or greenish; and is from a small vein in limestone at Antwerp, N. Y. It has not been analyzed, but is probably near algerite or wilsonite. The *Pinitartigen* (pinite-like) *Scapolit* of Schumacher (Verz., 98, 1801), from Arendal, is probably simi lar to the algerite and other *pinite* pseudomorphs. It is described as occurring in crystals anc massive, of a white, greenish, and other shades, and as B.B. fusing easily. His *Talkartiger Scapolit*, from Arendal, appears to have been a *steatitic* pseudomorph, it being B.B. infusible.

Mica from Arendal, Norway (*Micarelle* of Abildgaard). Anal. 15, 16. The mica occurs imbedded in quartz, and has, according to v. Rath (l. c.), the form of 8-sided crystals of scapolite, 6 in. long. The crystals are covered with mica externally, and within consist throughout of an aggregation of the same mica. The mica is greenish-white, translucent. H.=2—3. G.=2·833. Oxygen ratio (from v. Rath) 1 : 5·6 : 10·5; perhaps 1 : 6 : 10½, giving 1 : 1½ for the oxygen of the bases and silica. The change from scapolite has consisted in the removal of lime, addition of $\bar{\bar{F}}e$, and substitution of potash for soda.

Mica from Pargas, anal. 20, is a magnesia mica.

The *red* scapolite of Arendal (anal. 17) has H.=5; G.=2·852. Brownish or brick-red. Difficultly fusible. Oxygen ratio 1 : 2·4 : 7·5. In the change, $\bar{\bar{F}}e$, magnesia, and potash have been introduced.

The *black* scapolite of Arendal (anal. 18) is altered by a large addition of magnesia and iron Color grayish-black; streak grayish-white. Rather soft. G.=2·837. No cleavage. B.B. edges rounded with difficulty. O. ratio 1 : 2·1 : 2·5 : 1·6, unless part of the iron is sesquioxyd.

The *epidote pseudomorph* of the same locality (anal. 19) gives the oxygen ratio of epidote 1 : 2 : 3. The crystals occur imbedded in uralite. Forchhammer has described other epidote pseudomorphs after scapolite from Arendal, which are albite externally and epidote within.

GABBRONITE of Schumacher (Verzeichn., 1801) is referred here by Seemann, who observes that there are, in the Ecole des Mines at Paris, crystals of it of the form of scapolite (This Min., 506, 1854). Schumacher describes it as bluish-gray, inclining to leek-green; also grayish mountain-green; lustre feeble; fracture smooth like that of flint; G.=2·947; having some resemblance to gabbro. The bluish-gray variety from the Kenlig mine near Arendal, with black hornblende and calcite, and the other from Fredericksvärn, Norway, in syenite.

The *kaolin* from Malsjö, anal. 24, is a reddish-yellow clay-like mass, retaining something of the crystalline form of scapolite; G.=2·1. The composition corresponds to 1 of alumina to 2 of silica. For another kaolin see under EKEBERGITE (Passauite).

Steatitic pseudomorphs occur at Newton, N. J., and Arendal in Norway. A *siliceous* scapolite of Pargas, of a gray color, in limestone, contains 92·71 p. c. of silica. *Albite* is announced by Tschermak as occurring pseudomorphous after scapolite.

Pseudo-Scapolite of N. Nordenskiöld (Bidrag Finl. Min., 66, 1820) is wernerite altered to pyroxene. The crystals are large and contain crystals of pyroxene, which are most abundant toward the exterior; from Simonsby, near Pargas.

300. EKEBERGITE. Scapolite (fr. Arendal) pt. Wernerite (fr. Arendal) pt. [Syn. under WERNERITE.] Sodait (fr. Hesselkulla) *Ekeberg*, Afh., ii. 153, 1807. Natrolite of Hesselkulla *Wollaston*. Ekebergite *Berz.*, Arsb., 1824, 168. Ekebergit, Porzellanspath (fr. Passau) *J. N. Fuchs*, Denkschr. Ak. Munchen, vii. 65, 1818, Tasch. Min., xvii. 94, 1823. Porzellanit *v. Kob.* Taf., 52, 1853. Passauit *Naumann*, Min., 305, 1855.

Tetragonal. Like wernerite in form and cleavage. Also compact, or finely columnar massive.

H.=5·5—6. G.=2·74. Lustre vitreous, somewhat pearly or greasy. Color white, gray, greenish-white, bluish, reddish. Transparent to subtranslucent.

Comp.—O. ratio for $\dot{R}$, $\bar{\bar{R}}$, $\ddot{S}i$=1 : 2 : 4·5; formula $(\frac{1}{3}(\dot{C}a, \dot{N}a)+\frac{2}{3}\bar{\bar{A}}l)^2\ddot{S}i^3+3\ddot{S}i$; or else with half the excess of silica (or 1½ $\ddot{S}i$) basic; =, if $\dot{C}a : \dot{N}a$=3 : 1, Silica 51·7, alumina 26·3, lime 16·1, soda 5·9=100; if $\dot{C}a : \dot{N}a$=2 : 1, Silica 51·7, alumina 26·3, lime 14·2, soda 7·9=100.

Analyses: 1, Hermann (J. pr. Ch., xxxiv. 177); 2, Wolff (Inaug. Diss., Berlin, 1843, Ramm Min. Ch., 719); 3, Hartwall (Berz. Jahresb., iv. 155); 4, Wolff (l. c.); 5, v. * 1·35 p. c. of carbonate of lime removed.

Anal. 1, G.=2·80; 2, G.=2·735; 4, G.=2·628; 5, G.=2·658; 6, G.=2·712; 8, G.=2·633; 9, G. =2·64.

The *passauite* (Porcellanspath) has the O. ratio, in anal. 1, 1 : 2·4 : 4·8; in 2, 1 : 2·4 : 4·9; in 3, 1 : 2·2 : 4·6. But a slight change in the bases would make the last 1 : 2 : 4·5; and it is probable that the mineral is an altered ekebergite. Fuchs made the prisms probably about 92°, and so also did Schafhäutl. But Descloizeaux has found that it has but one optical axis—a negative one—and this decides it to be tetragonal in crystallization. Its colors are white to yellowish, bluish, and grayish-white. The crystals are coarse, and irregularly grouped or single.

Pyr., etc.—In the closed tube yield a small amount of water. B.B. whitens and fuses with intumescence to a blebby glass. Imperfectly decomposed by muriatic acid.

Obs.—From Hessellkulla and Malsjö in Sweden; Arendal in Norway; Pargas in Finland, in limestone; Gouverneur, St. Lawrence Co., N. Y., in limestone, with apatite and sphene, in short thick crystals sometimes several inches in diameter.

The passauite is from Appenzell, near Passau, in Bavaria.

Alt.—The passauite is the source, by its alteration, of a large bed of porcelain earth or kaolin. Part of the kaolin has the prismatic form of the passauite. Fuchs found in one of his analyses $\ddot{\mathrm{Si}}$ 45·06, $\ddot{\overline{\mathrm{Al}}}$ 32·00, $\ddot{\overline{\mathrm{Fe}}}$ 0·90, $\dot{\mathrm{Ca}}$ 0·74, $\dot{\mathrm{H}}$ 18·00, undecomposed mineral 2·96=99·66; in another $\ddot{\mathrm{Si}}$ 43·65, $\ddot{\overline{\mathrm{Al}}}$ 35·93, $\ddot{\overline{\mathrm{Fe}}}$ 1·00, $\dot{\mathrm{Ca}}$ 0·83, $\dot{\mathrm{H}}$ 18·50=99·91. Opal occurs in the kaolin as one result of the alteration.

PARALOGITE *N. Nordensk.* (Bull. Soc. Nat. Moscow, xxx. 221, 1857). Has the form and angles of scapolite (Koksch. Min. Russl., iii. 187), and is probably altered ekebergite. Colors white, bluish, reddish-blue; G.=2·665. The crystals, after action of acids, are full of worm-like holes, owing to the separation of the carbonate of lime present. Analysis afforded $\ddot{\mathrm{Si}}$ 44·95, $\ddot{\overline{\mathrm{Al}}}$ 26·89 $\dot{\mathrm{Mn}}$ *tr.*, $\dot{\mathrm{Mg}}$ 1·01, $\dot{\mathrm{Ca}}$ 14·44 [$\dot{\mathrm{Na}}$ 10·86], ign. 1·85=100. No potash was found. B.B. easily fusible. The O. ratio for $\dot{\mathrm{R}}$, $\ddot{\overline{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$ is 1 : 3 : 6; but supposing a loss of part of the bases, it may have been originally a true ekebergite. From the Lapis Lazuli locality near Bucharei in Siberia, in the L. Baikal region.

301. MIZZONITE. *Scacchi*, Pogg., Ergänz., iii. 478, 1852.

Tetragonal. Closely resembles meionite in its crystals. Observed planes: *O, I, i-i, i*-2, 1. *O* ∧ 1-*i*=156° 6′; *a*=0·4430; 1 ∧ 1=135° 56′ and 64° 8′, Scacchi; 135° 58′, Kokscharof. Cleavage as in meionite. Crystals quite small. Unknown massive.

H.=5·5–6. G.=2·623, v. Rath. Lustre vitreous. Colorless to white. Transparent to translucent.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\overline{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$=1 : 2 : 5¼; or, for bases and silica, =1 : 1¾; formula, $(\frac{1}{3}(\dot{\mathrm{Ca}}, \dot{\mathrm{Na}}) + \frac{2}{3}\ddot{\overline{\mathrm{Al}}})^3\ddot{\mathrm{Si}}^2 + 2\frac{1}{4}\ddot{\mathrm{Si}}$; or else with half the excess of silica basic; =, if $\dot{\mathrm{Ca}}$: $\dot{\mathrm{Na}}$=1 : 1, Silica 55·2 alumina 24·0, lime 9·9, soda 10·9=100. The analyses agree about as well with the O. ratio 1 : 2 : 5½

Analysis: v. Rath (Pogg., cix. 254):

$\ddot{\mathrm{Si}}$ 54·70 $\ddot{\overline{\mathrm{Al}}}$ 23·80 $\dot{\mathrm{Mg}}$ 0·22 $\dot{\mathrm{Ca}}$ 8·77 $\dot{\mathrm{Na}}$ 9·83 $\dot{\mathrm{K}}$ 2·14, ign. 0·13=99 59.

Pyr., etc.—B.B. fuses easily, but with less intumescence than meionite. Not acted upon by muriatic acid.

Obs.—Occurs on Somma, like the meionite, but is associated with feldspar instead of calcite Named from *μείζων*, *greater*, the axis of the prism being a little longer than in meionite

302. DIPYRE. Schorl blanchâtre de Mauléon (Pyrenees) (discov'd by Gillet-Laumont in 1786; Leucolite, *Delameth.*, Sciagr., i. 289, ii. 401, 1792. Dipyre *H.*, Tr., iii. 1801. Schmelzstein *Wern.* Steff. Orykt., i. 411, 1811. Couseranite *Charpentier*, Ann. Ch. Phys., xxxix. 280, 1828. Couseranite. Prehnitoid *Blomstrand*, Œfv. Ak. Stockh., 1854, 297.

Tetragonal. Form and cleavage same as for wernerite and meionite. Crystals small or large, single or grouped. Sometimes columnar.

H.=5–5·5. G.=2·646. Lustre vitreous to somewhat pearly. Colorless, whitish, yellowish, greenish, and sometimes reddish; opaque white. Transparent to subtranslucent.

Dipyre occurs in rather coarse crystals, often large or stout, and rarely columnar, in metamorphic rocks, while *marialite* is found only in very small colorless or white crystals, in igneous rocks, and contains more alkali. Prehnitoid is similar to dipyre.

Comp.—O. ratio for $\dot{\rm R}$, $\bar{\rm R}$, $\ddot{\rm Si}$=1 : 2 : 6; formula $(\frac{1}{3}(\frac{1}{2}\dot{\rm Ca}+\frac{1}{2}\dot{\rm Na})^3+\frac{2}{3}\bar{\rm Al})^2\ddot{\rm Si}^3+6\ddot{\rm Si}$=, if $\dot{\rm Ca}:\dot{\rm Na}$ =1 : 1, Silica 58·3, alumina 22·6, lime 9·1, soda 10·0.

Analyses: 1, Vauquelin (Haüy's Tr., iii. 1801); 2, Delesse (C. R., xviii. 994, 1844); 3, Damour (L'Institut, 16, 1862); 4, Pisani (Descl. Min., i. 227); 5, Blomstrand (Œfv. Ak. Stockh., 1854):

	$\ddot{\rm Si}$	$\bar{\rm Al}$	$\dot{\rm Mn}$	$\dot{\rm Mg}$	$\dot{\rm Ca}$	$\dot{\rm Na}$	$\dot{\rm K}$	$\dot{\rm H}$
1. *Dipyre*	60	24	——	——	10	4		2=100 Vauq.
2. " Libarens	55·5	24·8	——	——	9·0	9·4	0·7	——=99·4 Delesse.
3. " Pouzac	56·22	23·05	——	——	9·44	7·68	0·90	2·41=99·70 Damour.
4. " Libarens	56·69	22·68	0·39	0·49	6·85	8·65	0·78	4·55=101·08 Pisani.
5. *Prehnitoid*	56·00	22·45	0·18	0·36	7·79	10·07	0·46	1·04, $\dot{\rm Fe}$ 1·01=99·36 Bl.

Pyr., etc.—B.B. fuses with intumescence to a white blebby glass. Some specimens are phosphorescent when heated. Imperfectly decomposed by acids.

Obs.—From the region of the Hautes-Pyrenees, in granular limestone: at Pouzac, near Bagnères-de-Bigorre, with a white uniaxial mica; near Libarens, about a mile and a half from Mauléon, with mica or talc; at the baths of Aulus in the Dept. of Ariége; in a black schist on the right bank of the Lés, near Luzenac, Ariége; in the vicinity of Loutrin, near Angoumer, in blocks of granular limestone, with pyrite, sphene. The *prehnitoid* is from a locality between Kongsberg and Solberg in Sweden, with coarsely crystallized hornblende; its hardness is stated by Blomstrand to be 7, and G.=2·50.

The name *dipyre*, from δις, *twice*, and πῦρ, *fire*, alludes to the two effects of heat, *fusion* and *phosphorescence*. *Prehnitoid* refers to a resemblance to *prehnite*.

Alt.—Dipyre undergoes very easy alteration, much easier than wernerite, and this it probably owes to the large percentage of soda. At all the localities the mineral occurs to a large extent in a crumbling state. Some of it appears to be changed to a kind of greenish leuchtenbergite.

Couseranite appears to be the same mineral in an altered form. It occurs in the same region, and the dipyre may be seen passing into couseranite. Its square prisms are usually rough or rounded exteriorly, and bluish-black or grayish-black to deep black in color, but sometimes whitish and blackish on the same specimen. It is often soft and fragile. Charpentier's mineral came from the department of Ariége (formerly Couserans). Analyses: 1, Dufrénoy (Ann. d. M., II. iv. 327); 2, Pisani (Descl. Min., i. 234):

	$\ddot{\rm Si}$	$\bar{\rm Al}$	$\dot{\rm Fe}$	$\dot{\rm Mg}$	$\dot{\rm Ca}$	$\dot{\rm Na}$	$\dot{\rm K}$	$\dot{\rm H}$
1.	52·37	24·02	——	1·40	11·85	3·96	5·52	——=98·55 Dufr.
2.	58·33	20·20	1·90	7·20	0·99	0·76	8·82	2·35=100·55 Pisani.

Pisani's analysis was made on large square prisms from Pouzac. It has the composition of agalmatolite. Both of the analyses indicate the alteration by the amount of potash present.

Other localities are near Bagnères-de-Bigorre; at Sentenac near Seix, Ariége, in hard limestone. An orthoclase of the region has sometimes been mistaken for couseranite.

303. MARIALITE. *v. Rath*, ZS. G., xviii. 635, 1866. [Not Marialite of Ryllo.]

Tetragonal. Closely resembles meionite in its crystals. Form like f

288, except that O is present, and 3-3 are wanting. $1 \wedge 1 = 136° 0'$, nearly.

H.=5·5–6. G.=2·626; but, allowing for impurity, 2·530. Lustre vitreous. Colorless, or white. Transparent to translucent.

Comp.—O. ratio for $\dot{R}$, $\dddot{R}$, $\ddot{Si}$=1 : 2 : 6, like dipyre; but having the alkalies and lime in the ratio 2 : 1 instead of 1 : 1. Formula $(\frac{1}{3}(\frac{1}{3}\dot{C}a+\frac{2}{3}\dot{N}a)^3+\frac{2}{3}\dddot{A}l)^2\ddot{S}i^3+3\ddot{S}i$=Silica 58·3, alumina 22·3, lime 6·0, soda 13·4=100. Or perhaps ratio 1 : 2 : 6½, which gives silica 62·1, alumina 20·2, lime 5·5, soda 12·2, agreeing better with the analysis. Analysis: v. Rath (l. c.); 1*a* is the analysis with $\dddot{F}e$ removed as mixed magnetite:

	$\ddot{S}i$	$\dddot{A}l$	$\dddot{F}e$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$
1.	59·50	20·70	4·45	0·29	4·39	8·90	1·09=99·32.
1*a*.	62·72	21·82	——	0·31	4·63	9·37	1·15=100.

Pyr., etc.—Like those of mizzonite.

Obs.—From a volcanic rock called piperno, occurring at Pianura, near Naples.

---

304. NEPHELITE. Sechsseitige weisse durchsichtige Schörlsäuler mit oder ohne Pyramide an der Spitze, etc. (fr. Vesuvius (Somma)), *J. J. Ferber*, Briefe aus Wälschland, 166, 1773;=Basaltes crystallisatus albus crystallis prismaticis *v. Born*, Lithoph., ii. 73, 1775;=Sommite *Delameth.*, T. $I \wedge i\text{-}2 = 150$

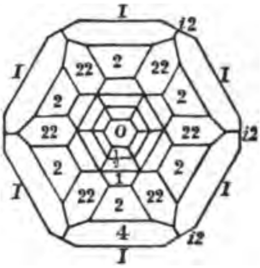
292



Vesuvius.

Cleavage: I distinct, O imperfect. Also massive, compact; also thin columnar.

H.=5·5–6. G.=2·5–2·65. Lustre vitreous—greasy; a little opalescent in some varieties. Colorless, white, or yellowish; also when massive, dark green, greenish or bluish-gray, brownish and brick-red. Transparent—opaque. Fracture subconchoidal. Double refraction feeble; axis negative.

Var.—1. *Glassy*, or Sommite. Usually in small crystals or grains, with vitreous lustre, first found on Mt. Somma, in the region of Vesuvius; G.=2·58, fr. Vesuvius, Scheerer; 2·637, ib., Breith. *Davyne* is nephelite from Vesuvius, with feeble lustre, containing, according to Rammelsberg, 12–14 p. c. of carbonate of lime, which he attributes to partial alteration; and *Cavolinite* is of the same locality; it has a silky lustre owing to longitudinal rifts within.

Kokscharof found the angle 1 ∧ 1=139° 17′; whence I ∧ 1=134° 5′ 22″, and a=0·83892((Min. Russl., ii. 160). Breithaupt made I ∧ 1=134° 5′; Haidinger 134° 3′; Scacchi 133° 57½.

2. *Elæolite.* In large coarse crystals, or massive, with a greasy lustre. G.=2·597, fr. Miask, Breith.; 2·65, fr. Arkansas, Smith & Brush.

Comp.—O. ratio for $\dot{R}$, $\bar{\text{R}}$, $\dddot{\text{Si}}$=1 : 3 : 4½. Formula perhaps $(\dot{\text{Na}}^3, \dot{\text{K}}^3)^2\,\dddot{\text{Si}}^3+3\,\bar{\text{Al}}^3\,\dddot{\text{Si}}^3+3\,\dddot{\text{Si}} = (\frac{1}{4}\dot{R}^3+\frac{3}{4}\bar{\text{Al}})^2\,\dddot{\text{Si}}^3+\frac{3}{4}\dddot{\text{Si}}$. Possibly $7\,(\frac{1}{4}\dot{R}^3+\frac{3}{4}\bar{\text{Al}})^2\,\dddot{\text{Si}}^3+2\,(\frac{1}{4}\dot{R}^3+\frac{3}{4}\bar{\text{Al}})\,\dddot{\text{Si}}^2$, making it a combination of a unisilicate and a bisilicate. The percentage corresponding to either, is, if $\dot{\text{Na}} : \dot{\text{K}}$=5 : 1, silica 44·2, alumina 33·7, soda 16·9, potash 5·2=100.

Analyses: 1, Arfvedson (Jahresb., ii. 97); 2, 3, 4, Scheerer (Pogg., xlvi. 291, xlix. 359), 5. Gmelin (Neph. im Dolerit, etc., Heidelberg, 1822); 6, Heidepriem (J. pr. Ch., l. 500); 7, Monticelli & Covelli (Prod. Min. Vesuv., 375, and Pogg., xi. 470); 8, 9, Rammelsberg (Pogg., cix. 579, and Min. Ch., 652); 10, 11, 12, Scheerer (Pogg., xlvi. 291, xlix. 359); 13, 14, Bromeis (Pogg., xlviii. 577); 15, P. v. Pusirevsky (Koksch. Min. Russl., iii. 78); Smith & Brush (Am. J. Sci., II. xvi 371); 17, J. P. Kimball (Am. J. Sci., II. xxix. 65); 18, D. M. Balch (Proc. Essex Inst., iv. 5).

[a] With Mn^2O^3.

In the last analysis, the mineral, previous to analysis, had been dried at 150° C.; when dried at 100 C., it afforded 1·31 p c. of water. Traces of muriatic acid, and also of sulphuric, were detected by Scheerer and Bromeis; and in one nepheline from Mt. Somma they found 0·22 of the former and 0·10 of the latter. Other analyses: of E. fr. Norway, Scheerer, Pogg., cxix., 145; N. fr. Meiches in the Vogelsgeb., A. Knop, Jahrb. Min., 1865, 686.

Pyr., etc.—B.B. fuses quietly at 3·5 to a colorless glass. Gelatinizes with acids.

Obs.—Nephelite occurs both in ancient and modern volcanic rocks, and also metamorphic rocks allied to granite and gneiss, the former mostly in glassy crystals or grains (sommite), the latter massive or in stout crystals (elæolite). A dolcryte containing much disseminated nepheline, such as occurs at Katzenbuckel, near Heidelberg, has been called *nephelinophyre* and *nephelindoleryte*. A granite-like rock found near Miask, in which elæolite replaces quartz, has been named *miascyte*, from its locality. A rock composed of orthoclase, elæolite, and sodalite, from Ditro in Transylvania, is the *ditröyte* of Tschermak. The zircon-syenite of Norway contains much elæolite.

Nephelite occurs in crystals in the older lavas of Somma, with mica, idocrase, etc.; at Capo di Bove, near Rome (the locality of the *pseudo-nepheline*); in the clinkstone of Katzenbuckel, near Heidelberg; at Hamberg in Hessia; Aussig in Bohemia; Löbau in Saxony. Elæolite is found at Brevig, Stavern, and Fredericksvärn, Norway, imbedded in zircon-syenite; in the Ilmen Mts., Urals, along with white feldspar, brown hexagonal mica, zircon, pyrochlore, etc.; at Marienskaja in the Tunkinsk Mts., Siberia, with graphite, cancrinite, zircon. The crystal measured by Scacchi was of the variety *sommite*, or *davyne*, occurring at Somma in a geode in limestone with sodalite (Pogg. Erganz., iii. 478, 1858).

Elæolite occurs massive and crystallized at Litchfield, Me., with cancrinite; in the Ozark Mts., Arkansas, with brookite and schorlomite; in a boulder, with sodalite, at Salem, Mass.

Named *nepheline* by Haüy (1801), from νεφελή, *a cloud*, in allusion to its becoming cloudy when immersed in strong acid; *elæolite* (by Klaproth), from ἔλαιον, *oil*, in allusion to its greasy lustre, the variety having been made a distinct species earlier by Werner (1808), under the German name of [illegible]*tein*. The name *sommite*, derived from the Vesuvian locality, given in 1797 by Delametherie, [illegible] priority. But Werner early adopted Haüy's name, and later authors have all taken the [illegible]se.

A mineral from Norway, of a yellowish-brown color, called *phonite*, is very much like elæolite, according to Descloizeaux.

Alt.—Nephelite or elæolite is liable to ready alteration, and usually produces a zeolite, as *thomsonite*. The *Ozarkite* of Shepard, according to Smith and Brush, is *thomsonite* (q. v.), and its situation in cavities in elæolite shows that it is a product of alteration. The large amount of soda in nephelite compared with the silica fits it especially for generating zeolites. Blum attributes bergmannite to the alteration of elæolite (Pogg., lxxxvii. 315, and cv. 133).

Gieseckite is shown by Blum to be a pseudomorph after this species. It differs mainly in containing several per cent. of water. It occurs in six-sided greenish-gray prisms of greasy lustre, in Greenland, having $O \wedge 1=135°$ nearly; and also at Diana, in Lewis Co., N. Y., with the same angles, for the most part, although the results of measurement vary between 131° and 139°. The crystals of Diana are hexagonal in cleavage? yet the planes of cleavage are often separated by layers of a waxy appearance, without lustre or cleavage. According to Descloizeaux, the material of the crystals acts on polarized light like a gum or colloid, and is evidently a result of alteration. *Liebenerite*, from the valley of Fleims, in the Tyrol, is considered by Blum a similar pseudomorph, and Descloizeaux sustains this conclusion. See further PINITE, under HYDROUS SILICATES.

Elæolite has been observed altered also to mica and opal. *Davyne* is regarded as altered nephelite, due to the introduction of carbonic acid, as stated above; and *cancrinite* is supposed to have had the same origin.

304A. CANCRINITE. *G. Rose*, Pogg., xlvii. 779, 1839.

Hexagonal, and in six and twelve-sided prisms, sometimes with basal edges replaced; $O \wedge \frac{1}{2}=154° 7'$, $I \wedge \frac{1}{2}=115° 53'$, $\frac{1}{2} \wedge \frac{1}{2}=154° 47'$; also thin columnar and massive. H.=5—6. G.=2·42—2·5. Color white, gray, yellow, green, blue, reddish; streak uncolored. Lustre subvitreous, or a little pearly or greasy. Transparent to translucent.

Comp.—Formula the same as for nepheline, with some $\dot{R}\ddot{C}$ and $n\dot{H}$, $\dot{R}$ of the silicate to that of the carbonate being mostly as 3 : 1. Rose found no water. Analyses: 1, 2, G. Rose, (Pogg., xlvii. 779); 3, Pusirevsky (Koksch. Min. Russl., iii. 76); 4, 5, J. D. Whitney (Pogg., lxx. 431); 6, v. Struve (Pogg., xc. 615); 7, Pusirevsky (l. c.); 8, G. Tschermak (Ber. Ak. Wien, xliv. 134); 9, Pisani (Ann Ch. Phys., III. lxvii.):

9. Barkevig	41·52	28·09	4·11	17·15	—	3·60	6·60=101·07 Pisani.

G.=2·448, yellow, fr. Litchfield, Me., Whitney; 2·461, green, ib.; 2·489, rose-red (anal. 3), fr. Ilmen Mts., Pusirevsky; 2·454, yellow (anal. 7), fr. Tunkinsk Mts., id.; 2·42, fr. Ditro (anal. 8), Tschermak; 2·404, fr. Barkevig, Pisani (anal. 9).

Cancrinite is closely like nephelite in crystalline form, and it is probably identical with it in atomic ratio, excepting the carbonate and water, which may be due, as stated, to alteration. Davyne is intermediate in composition, and differs only in that it has the carbonic acid combined with lime alone.

Whitney found a trace of chlorine in his analyses. The red color of the Miask cancrinite is due to disseminated grains of hematite, according to Kenngott, who also found calcite in microscopic grains, and suggests that this may be the source of the carbonic acid of cancrinite.

Pyr., etc.—In the closed tube gives water. B.B. loses color, and fuses (F.=2) with intumescence to a white blebby glass, the very easy fusibility distinguishing it readily from nephelite. Effervesces with muriatic acid, and forms a jelly on heating, but not before.

Obs.—Found at Miask in the Urals; of citron-yellow color at the Marienskoy graphite mine in the Tunkinsk Mts., 400 versts west of Irkutsk, in a coarse granite, with zircon, calcite, and magnetite; at Barkevig, in the Langesund-fiord, Norway, whitish and pale yellowish, with blue sodalite and "bergmannite;" at Ditro in Transylvania, pale flesh-red, in the rock called *ditroyte*, consisting of orthoclase, elæolite, and sodalite (anal. 8). In crystals and massive, with blue sodalite, at Litchfield, Me.

Alt.—Occurs altered to natrolite (*bergmannite*); the cancrinite, as Seemann and Pisani observe first losing its translucence and then passing to the fibrous condition and nature of the zeolite.

---

305. SODALITE. Sodalite (fr. Greenland) *Thomson*, R. Soc. Ed. Tr., v. 387, read Nov. 1810 Phil. Mag., xxxvi. 303, 1810.

Isometric. In dodecahedrons, f. 3; also 4, 5, 10, 11, 14. Cleavage: dodecahedral, more or less distinct. Twins: hexagonal prisms, terminating in 12 planes forming 6 prominent triangular ridges of 120°, radiating from the centre, and arising from a combination of dodecahedrons. Also massive.

H.=5·5—6. G.=2·136—2·26, Vesuvius; 2·401, fr. Scarrupata, v. Rath; 2·289, Ural; 2·37, Greenland; 2·294—2·314, Salem, Kimball. Lustre vitreous, sometimes inclining to greasy. Color gray, greenish, yellowish, white; sometimes blue, lavender-blue, light red. Subtransparent—translucent. Streak uncolored. Fracture conchoidal—uneven.

Comp.—$(\frac{1}{4}\dot{N}a^3+\frac{3}{4}\ddot{\bar{A}}l)^2\ddot{S}i^3+\frac{1}{2}NaCl=(\dot{N}a^3)^2\ddot{S}i^3+3\ddot{\bar{A}}l^3\ddot{S}i^3+2NaCl$=Silica 37·1, alumina 31·7, soda 19·2, sodium 4·7, chlorine 7·3=100. The name alludes to the *soda*. J. D. Whitney suggests that the blue color may be owing to ferric acid present.

Analyses: 1, Ekeberg (Thomson's Ann. Phil., i. 104); 2, Thomson (l. c.); 3, Arfvedson (Jahresb., ii. 97); 4, 5, Rammelsberg (Min. Ch., 702); 6, v. Rath (ZS. G., xviii. 621); 7, Hofmann (Pogg., xlvii. 377); 8, v. Borc (Pogg., lxxviii. 413); 9, 10, Whitney (Pogg., lxx. 481); 11, J. P. Kimball (Am. J. Sci., II. xxix. 67); 12, D. M. Balch (Proc. Essex Inst., Salem, iv. 4):

[a] With some potash. [b] Traces of Sn, Mn, W, and Mo. [c] With some Fe^2O^3.

Pyr., etc.—In the closed tube the blue varieties become white and opaque. B.B. fuses with intumescence, at 3·5—4, to a colorless glass. Decomposed by muriatic and nitric acids, with separation of gelatinous silica.

Obs.—Occurs in mica slate, granite, syenite, trap, basalt, and volcanic rocks, and is often associated with nephelite (or elæolite) and eudialyte. With sanidine it forms a *sodalite-trachyte* at Scarrupata in Ischia, in which also occur augite, titanite, and magnetite in crystals. Found in West Greenland in mica slate, along with feldspar, arfvedsonite, and eudialyte; at Vesuvius, on Monte Somma, in white, translucent, dodecahedral crystals, with pyroxene, mica, and rarely in green dodecahedrons, with cubic planes, in limestone along with idocrase and nepheline; massive and of a gray color imbedded in trap at the Kaiserstuhl in Brisgau; also near Lake Laach; in Sicily, Val d' Noto, with nephelite and analcite; at Miask, in the Ural, blue in the granite-like rock called *miascyte*, with elæolite and feldspar; Sedlowatoi, in the White Sea, with eudialyte; in nodular masses at Lamöe near Brevig, Norway, of a lavender-blue color, with elæolite, wöhlerite, and rarely eudialyte.

A blue variety occurs at Litchfield, Me., massive, with distinct cleavage, associated with elæolite, zircon, and cancrinite; a lavender-blue, in a vein in syenite, at Salem, Mass., violet to azure blue, with elæolite, orthoclase, biotite, and zircon.

Bergemann obtained for a greenish mineral having G.=2·502, occurring with elæolite at Brevig in Norway (Pogg., lxxxiv. 492), S̈i 46·03, A̶l 23·97, Ṅa 21·48, Cl 7·43, P̶ 0·86, Ċa, F̶e *tr.*=99·77; it gives the formula of anorthite (oxygen ratio 1 : 3 : 6) with an addition of some chlorid of sodium; but it may be only an impure sodalite.

Named in allusion to its containing soda.

Alt.—Sodalite occurs altered to kaolin, like the feldspars, and also in conditions of partial change.

An altered sodalite from Greenland afforded Rammelsberg S̈i 43·20, A̶l 32·54, Ċa 3·00, Ṅa 11·42, Cl *tr.*, Ḣ (by loss) 9·84, giving for Ṙ, A̶l, S̈i, Ḣ, the oxygen ratio 1 : 4 : 6 : 2; but it is not regarded by this chemist as a distinct chemical compound.

Trolle-Wachtmeister found a Vesuvian sodalite to contain (Pogg., ii. 14) S̈i 50·98, A̶l 27·64, Ṅa 20·96, Cl 1·26=100·84, which must have been either very impure or altered.

306. LAPIS-LAZULI. Σάπφειρος *Theophr.* Sapphiros *Plin.*, xxxvii. 39. Sapphirus *Agric.*, Foss., 288, 1546. Pyr., etc.—Heated in the closed tube gives off some moisture; the variety from Chili glows with a beetle-green light, but the color of the mineral remains blue on cooling. Fuses easily (3) with intumescence to a white glass. Decomposed by muriatic acid, with separation of gelatinous silica and evolution of sulphuretted hydrogen.

Obs.—It is usually found in syenite or crystalline limestones, associated often with pyrite and mica in scales.

Occurs of a deep blue color in Siberia, at Bucharei, in limestone, with pyrite, apatite, and glaucolite; near the river Talaja, and also the Bystraja, in the Lake Baikal region, in a crystalline limestone containing mica, in syenite; also on the Slüdianka in the same region; at Ditro in Transylvania, in a hornblendic vein in syenite; in Persia; China; Thibet; at Bardakschan in Tartary; in the Andes of Ovalle, near the sources of the Cazadero and Vias, tributaries of tho Rio Grande, in a granitic rock. On the banks of the Indus it is disseminated in grayish limestone.

The richly colored varieties of lapis lazuli are highly esteemed for costly vases and ornamental furniture; also employed in the manufacture of mosaics; and when powdered constitutes the rich and durable paint called *ultramarine.* B. de Boot gives, in his work above referred to, the method employed for making artificial ultramarine. An ultramarine, chemically prepared, equal to that from native lapis lazuli in color and permanency, and now extensively used in the arts, contains, according to Varrentrapp,

S̈i 45·604, S⃛ 3·880, A̶l 23·304, Ċa 0·021, Ṅa 21·476, K̇ 1·752, S 1·685, Fe 1·063, Cl *tr.*=98·785.

307. HAÜYNITE. Latialite (fr. the Campagna, ancient Latium) *Gismondi*, in Mem. read in 1803, before the Acad. de Lincei at Rome, but unpublished. Haüyne *Bruun-Neergard*, Schw. J., iv. 417, 1807, J. d. M., xxi. 365, 1807. Auina *Ital.* Berzeline *L. A. Necker*, Bibl. Univ., xlvi 52, 1831, Regne Min. Paris, 1835; *v. Rath.* ZS. Isometric. In dodecahedrons, octahedrons, etc., f. 3—7; also with planes 3, 3-3. Cleavage: dodecahedral distinct. Twins: composition-face octahedral, as in f. 293, parallel to all the planes 1; and f. 294, parallel to one plane, with faces of the dodecahedron. Commonly in rounded grains often looking like crystals with a fused surface.

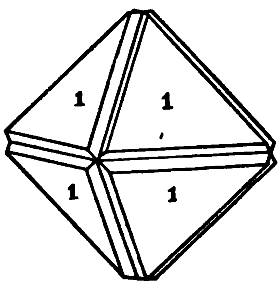
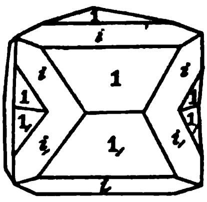
293



Albano.

294



Albano.

H.=5·5—6. G.=2·4—2·5; Lustre vitreous, to somewhat greasy. Color bright blue, sky-blue, greenish-blue; asparagus-green. Streak slightly bluish to colorless. Subtransparent to translucent. Fracture flat conchoidal to uneven.

Var.—For the mineral fr. Marino, G.=2·833, Gmelin; fr. Vesuvius, G.=2·464, Ramm.; fr. Melfi, G.=2·466, Scacchi; fr. L. Laach, 2·481, v. Rath. The white variety from near Albano is *Berzeline* of Necker, according to v. Rath (l. c.), from whom figs. 293, 294, representing twins of it, are taken. Vom Rath remarks that the mineral analyzed by Gmelin (Obs. de Hauyna, etc.), which has been referred to berzeline, was a mixture.

Comp.—$(\frac{1}{4}\dot{Na}^3+\frac{3}{4}\bar{\ddot{Al}})^2\ddot{Si}^3+\dot{Ca}\bar{\dddot{S}}=(\dot{Na}^3)^2\ddot{Si}^3+3\bar{\ddot{Al}}^3\ddot{Si}^3+4\dot{Ca}\bar{\dddot{S}}$=Silica 32·0, alumina 27·4, lime 9·9, soda 16·5, sulphuric acid 14·2=100. [a] $\dot{H}$, S, and loss.

The haüynite from Niedermendig, according to Whitney, corresponds in composition to 2 haüynite+1 nosite.

Pyr., etc.—In the closed tube retains its color. B.B. in the forceps fuses at 4·5 to a white glass. Fused with soda on charcoal affords a sulphid, which blackens silver. Decomposed by muriatic acid with separation of gelatinous silica.

Obs.—Occurs in the Vesuvian lavas, on Somma; at Melfi, on Mt. Vultur, Naples, in a kind of lava called *Haüynophyr*, a black to brown rock containing the haüynite disseminated through it, of black, green, blue, red, and brown colors, and also white, and sometimes red inside and blue outside; in the lavas of the Campagna, Rome, and also in the peperino of Marino and Ariccia near Albano, of sky-blue, bluish-green, and sometimes opaline, also white (*berzeline*); in basalt at Niedermendig and Mayen. L. Laach, in a trachytic rock; at Mt. Dor in Puy de Dome: at St Michael's, Azores.

Named after the crystallographer and mineralogist Haüy.

Alt.—The variations in the analyses as to water present show a tendency to hydration and to other changes in the mineral.

ITTNERITE *Gmelin* (Schw. J., xxxvi. 74, 1822); SKOLOPSITE *v. Kobell* (Gel. Anzeig., xxviii. 638, 1849). Rammelsberg has shown (Ber. Ak. Berlin, 1862, 1864) that ittnerite and skolopsite are probably altered haüynite or nosite. Ittnerite contains 10 to 12 p. c. of water, and scolopsite varies in the water from none to 10 p. c. Ittnorite occurs in translucent dodecahedrons or granular massive, with H.=5·5; G.=2·37—2·40; color dark bluish or ash-gray to smoky gray; lustre resinous, and comes from Kaiserstuhl near Freiberg, in Brisgau, Sasbach, and Endingen.

Scolopsite occurs granular massive; H.=5; G.=2·53, color grayish-white, to pale reddish-gray, and is from Kaiserstuhl, and occurs in the same rock with ittnerite (Fischer, Ber. Ges. Freiburg, 1862).

Analyses: 1, Gmelin (l. c.); 2, J. D. Whitney (Pogg., lxx. 442); 3, Rammelsberg (Ber. Ak. Berlin, 1864, 171); 4, v. Kobell (l. c.); 5, Rammelsberg (l. c., ii. 1862, 245); 6, id. (ib., 1864, 172):

Klaproth, in his analysis (Beitr., vi. 375), obtained $\ddot{\mathrm{Si}}$ 43·0, $\dddot{\overline{\mathrm{Al}}}$ 29·5, $\dddot{\overline{\mathrm{Fe}}}$ 2·0, $\dot{\mathrm{Ca}}$ 1·5, $\dot{\mathrm{Na}}$ 19·0, $\dddot{\mathrm{S}}$ 1·0, $\dot{\mathrm{H}}$ 2·5=98·5.

Pyr., etc.—B.B. like haüynite. Gelatinizes in acids, yielding no sulphuretted hydrogen.

Obs.—From near Andernach on the Rhine, at Lake Laach, in loose blocks consisting largely of a glassy feldspar, with mica, magnetite, and occasionally zircon, occupying cavities in the feldspar, in small grains or crystals; also found at Rieden and Volkersfeld in a leucite rock.

Named after K. W. Nose of Brunswick.

Potash, regarded long as an alkali exclusively of the vegetable kingdom, was first found among minerals in this species by Klaproth, whose earliest analysis was made in 1796.

Rammelsberg does not find the large proportion of soda announced for some kinds by Bischof. According to Deville, the leucite of the modern Vesuvian lavas contain more soda than that of the ancient of Somma, the ratio of soda to potash in that of the lava of 1855 being 1 : 2·09; in the 1847, 1 : 1·67; and in the Somma, 1 : 8·21. Specimen for anal. 7 is from lava of 1811, colorless, transparent, G.=2·480; for 8, id., in grains; for 9, 10, pure crystals from the Vesuvian eruption of Ap. 22, 1845; for 11, id. of Feb. 10, 1847; for 12, id. of January, 1857; for 13, date of eruption not stated; for 14, 15, small crystals, externally somewhat altered; 16, large, fragile, yellow crystals, of feeble lustre and little hardness; 17, the same; 18–20, of different parts of same crystals, 18 the exterior, 20 the interior, and 19 an intermediate portion.

By spectral examination, Richter has detected lithia in the Vesuvian leucite.

Pyr., etc.—B.B. infusible; with cobalt solution gives a blue color (alumina). Decomposed by muriatic acid without gelatinization.

Obs.—Leucite is confined to volcanic rocks, and to those of certain parts of Europe. At Vesuvius and some other parts of Italy it is thickly disseminated through the lava in grains, and the name *leucitophyr* and also *amphigenyte* has been given to such lavas. It is a constituent in the nephelin-doleryte of Merches in the Vogelsberg (anal. 21); abundant in trachyte between Lake Laach and Andernach, on the Rhine. Vesuvius presents the finest and largest crystallizations. Near Rome, at Borghetta to the north, and Albano and Frascati to the south, some of the older lavas appear to be almost entirely composed of it.

The leucitic lava of the neighborhood of Rome has been used for the last two thousand years, at least, in the formation of mill-stones. Mill-stones of this rock have been discovered in the excavations at Pompeii.

Named by Werner from λευκός, *white*, in allusion to its color.

Haüy's name, *Amphigene*, is of later date, and is from αμφι, *both*, and γενναω, *to make*, in allusion to the existence of cleavage in two directions (which is not a fact), and to his inference therefrom of two "primitive forms" (which is only a notion of his); and it has therefore the best of claims for rejection.

Alt.—Feldspar, nephelite, and kaolin occur with the form of leucite, as a result of its alteration. The glassy feldspar pseudomorphs were first announced by Scacchi, and since by Blum. The following are analyses of altered leucite: 1, 2, Rammelsberg (Min. Ch., 647); 3, C. Stamm (Ann. Ch. Pharm., xcix. 287); 4, 5, Rammelsberg (Min. Ch., 647); 6, Bergemann (J. pr. Ch lxxx. 418):

The mineral of 1 and 2 is white and kaolin-like; 3, occurs in trachyte; 4, 5, are Somma crystals, and A, under each, part of same decomposable by muriatic acid; B, part undecomposable; 6, crystal, having H.=5·5, G.=2·5616.

No. 3 has nearly the composition of analcite, and was published as of that species. But Rose (Pogg., ciii. 521) and others make it an altered leucite, with the composition of analcite. 1 and 2 are nearly the same in constitution with 3, as Rammelsberg states. 4, 5, correspond, according to Rammelsberg, to a mixture of nephelite (A part) with glassy feldspar (B part); and yet has the composition of a *potash-soda-leucite*. 6 has the composition and reactions nearly of *oligoclase* (oxygen ratio, 1 : 3·1 : 9·4); it lost by ignition 1·22 p. c.; 5·97 p. c. were soluble in muriatic acid, and consisted of $\ddot{\mathrm{Si}}$ 3·50, $\ddot{\overline{\mathrm{Al}}}$ 1·60, $\dot{\mathrm{Fe}}$ 0·05, $\dot{\mathrm{Mg}}$ 0·04, $\dot{\mathrm{Na}}$ *tr.*, $\dot{\mathrm{K}}$ 0·47, $\dot{\mathrm{Ca}}$, $\dot{\mathrm{Mn}}$ *tr.*

FELDSPAR GROUP.

The feldspars are characterized by specific gravity below 2·85; hardness 6 to 7; fusibility 3 to 5; oblique or clinohedral crystallization; prismatic angle near 120°; two easy cleavages, one basal, the other brachydiagonal, inclined together either 90°, or very near 90°; cleavage a prominent feature of many massive kinds, and distinct in the grains of granular varieties, giving them angular forms; close isomorphism, and a general resemblance in the systems of occurring crystalline forms; twinning parallel to the clinodiagonal section and *O*, and sometimes 2-ĭ (or the corresponding triclinic planes); transition from granular varieties to compact, hornstone-like kinds, called felsites, which sometimes occur as rocks; often opalescent, or having a play of colors as seen in a direction a little oblique to *i-ĭ*; often aventurine, from the dissemination of microscopic crystals of foreign substances parallel for the most part to the planes *O* and *I*.

The protoxyd bases are lime, soda, potash, and in one species baryta; the sesquioxyd only alumina; the oxygen ratio of the protoxyds and sesquioxyds is constant, 1 : 3; while that of the silica and bases varies from 1 : 1 to 3 : 1, the amount of silica increasing with the increase of alkali, and becoming greatest when alkalies are the only protoxyds.

The included species are as follows:

		Crystallization.	O. ratio $\dot{R}$, $\bar{\bar{R}}$, $\ddot{Si}$
ANORTHITE	Lime feldspar	Triclinic	1 : 3 : 4
LABRADORITE	Lime-soda feldspar	"	1 : 3 : 6
HYALOPHANE	Baryta-potash feldspar	Monoclinic	1 : 3 : 8
ANDESITE	Soda-lime feldspar	Triclinic	1 : 3 : 8
OLIGOCLASE	" " "	"	1 : 3 : 9
ALBITE	Soda feldspar	"	1 : 3 : 12
ORTHOCLASE	Potash feldspar	Monoclinic	1 : 3 : 12

The species appear in the analyses beyond to shade into one another by gradual transitions; but whether this is the actual fact, or whether the seeming transitions (when not from bad analyses) are due to mixtures of different kinds through contemporaneous crystallization, is not positively ascertained. The latter is the most reasonable view. It has been shown by Breithaupt and others that orthoclase and albite (or the *potash* and *soda* feldspars) occur together in infinitesimal interlaminations of the two species, and that the soda-potash variety called *perthite* (p. 356) is one of those thus constituted. This structure is apparent under a magnifying power, and also when specimens are examined by means of polarized light. Moreover, these and other feldspars very commonly occur side by side or intercrystallized when not interlaminated; as oligoclase and orthoclase in the granite of Orange Summit, N. Hampshire, and Danbury, Conn.; in obsidian in Mexico; in trachytes of other regions. Such facts show that the idea of indefinite shadings between the species is probably a false one, since the two keep themselves distinct, and, in the perthite and similar cases, even to microscopic perfection. They also make manifest that contemporaneous crystallization is a true cause in many cases.

Intermediate varieties may also come through alteration under the agency of infiltrating waters. Water filtrated through powdered feldspar of any kind soon becomes alkaline by taking up part of the bases. Moreover there is a strong tendency to alteration, and the final production of kaolin, a change involving the loss of all the protoxyd bases, and also much of the silica, the oxygen ratio of the silica and alumina being thus reduced to 1 : 1, from 3 : 1 in orthoclase or albite, and from 2 : 1 in labradorite.

The species andesite is still a doubtful one.

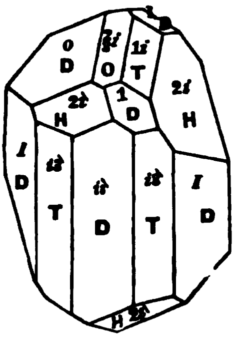
The play of colors, especially remarkable in much labradorite, and occurring also in some adularia, albite, and oligoclase, indicates, according to Reusch (Pogg., cxvi. 392, cxviii. 256, cxx. 95), the existence of a cleavage structure of extreme delicacy transverse to the median or brachydiagonal section. In adularia the plane of this cleavage is perpendicular to this section (or that of the clinodiagonal); in labradorite it is in general more or less inclined and differently in different specimens. The play of color, Reusch observes, appears therefore to be that of thin plates; yet the linings of what he regards as a cleavage system appear to be of indistinguishable minuteness; and although the existence of thin plates can hardly be established by means of the microscope, it is proved by their effects in the play of colors, nebulous images within, and the phenomena of inflexion or diffraction which result from their regular grouping. There appears to be no connection between the inclination of the plane in labradorite and the colors observed. The play of colors is best seen on a plate polished parallel to the brachydiagonal section (*i-ĭ*), when, as Descloizeaux states, it is turned to the right or left on an axis slightly oblique to the face, which extends toward the obtuse angle between the edges *O*/*i-ĭ* and *I'*/*i-ĭ*, and makes an angle of about 70° with the edge *O*/*i-ĭ*; and the maximum effect is produced in two positions situated 15° to 50° from one another, which are unequally inclined to the face *i-ĭ*.

The play of colors is independent of the disseminated microscopic crystals of foreign substances which occasion the aventurine effect.

The feldspars are intimately related to the isometric species of the Leucite group. Leucite has the oxygen ratio 1 : 3 : 8, one of the feldspar ratios; so that isometric leucite, monoclinic hyalophane, and triclinic andesite (if this species is sustained), form a trimorphous group. But while the form of leucite appears at first sight to be very unlike that of the true feldspars, there is actually approximate isomorphism. For the monoclinic and triclinic forms are strictly oblique or clinohedrized dodecahedrons.*

If a dodecahedron be so placed that an octahedral axis, that is, the line between the apices of two of the trihedral solid angles, is vertical, it is then a six-sided prism with trihedral summits. If now this axis be inclined 8° 6′ in one of the diametral planes of the six-sided prism, it will have the inclination of the axis of orthoclase; and this 8° 6′ is the greatest amount of divergence from the dodecahedral angles that occurs in the species. The planes *I*, *i-ì* incline to one another at angles near 120°, and correspond to the 6 vertical planes of the dodecahedron (as above placed). The basal plane *O* is also dodecahedric, for *O* ∧ *I*=122° 16′, and *O* ∧ *i-ì* (dodecahedric)=90°. The four planes 1 are also dodecahedric, as shown by their position and inclinations. Thus all the *twelve* faces of the dodecahedron occur in the above figure; they are lettered **D**.

296



Again, the planes *i-3* and 1-ì, which replace the edges between the dodecahedric planes *I*, *i-ì* and 1, 1, with angles near 150°, correspond to planes of the trapezohedron 2-2 (that truncating the dodecahedron, f. 14), and consequently the figure contains *six* trapezohedric planes; they are lettered **T**.

Again, the planes 2-ì are cubic; for they make with the dodecahedric plane *O* the angle 135° 8′, varying but 8′ from the isometric angle. 2-ì is another cubic face; it is inclined to *I*, a dodecahedric plane, 134° 19′. There are present, therefore, all *six* faces of the cube; they are lettered **H**.

Finally the plane ⅔-i, at the top of the figure (and the only remaining one), lettered **O**, is octahedric, as shown by its intersections with the cubic, dodecahedric, and trapezohedric faces; and also by its inclination to the cubic face 2-*i*=124° 51′, and to the dodecahedric face *I*=145° 47′, these angles in isometric forms being 125° 16′ and 144° 44′.

It follows then that the above figure contains the *dodecahedric* planes *I*, *I*, *i-ì*, *O*, 1, 1, with their opposites, or the whole *twelve*; the *trapezohedric* *i-3*, *i-3*, 1-*i*, with their opposites, or *six*; the *octahedric*, ⅔-*i*, with its opposite, or *two*; and the cubic 2-ì, 2-ì 2-*i*, or all *six*; and no others. The angles of the *oblique cube* are 2-ì ∧ 2-ì, over *O*,=90° 6′, 2-ì ∧ 2-*i*=96° 48′. Moreover, the normal apex of the clinohedrized dodecahedron is that part of the crystal occupied by the octahedric plane ⅔-*i*; in other words, ⅔-*i* is normally the *basal* plane, and not *O*; and the true inclination of the vertical axis is 8° 6′ (the angle ⅔-*i* ∧ *i-i* being 98° 6′).

Accordingly the two cleavages in orthoclase, parallel to *O* and *i-ì*, are both dodecahedric. Moreover, the directions of twinning are either dodecahedric (parallel to *i-ì*, which is the most common, and *O*), or cubic (parallel to 2-ì).

These relations hold true also for the triclinic feldspars, the only peculiarity in which is that the principal section has slight lateral obliquity, so that the two cleavage planes (dodecahedric) incline to one another 93° 15′ to 94° 15′ instead of 90°. G. Rose, in an article on albite (Pogg., cxxv. 457), alludes to the remarkable fact that the planes 2-ì (see p. 349), either side of *O*, make with one another in this species very nearly a right angle (90° 35′, Neumann, and 90° 4′, Descloizeaux). The fact is not so surprising when it is observed that the planes 2-ì are *cubic* faces. They correspond to 2-ì in orthoclase.

Observed Planes.

Cleavage: *O*, *i*-ĭ perfect, the latter least so. Twins similar to those of albite. Also massive. Structure granular, or coarse lamellar.

H.=6—7. G.=2·66—2·78; 2·70—2·75, Iceland, Urals, Corsica; 2·762, massive, Rose; 2·763, amphodelite; 2·668, indianite, Silliman. Lustre of cleavage planes inclining to pearly; of other faces vitreous. Color white, grayish, reddish. Streak uncolored. Transparent—translucent. Fracture conchoidal. Brittle. Optic-axial angle large; one bisectrix positive and nearly normal to *i*-ī, the other negative and sensibly oblique to *i*-ĭ.

Var.—1. *Anorthite* was described from the glassy crystals of Somma; and *christianite* and *biotine* are the same mineral. *Thiorsauite* is the same from Iceland.

2. *Indianite* is a white, grayish, or reddish granular anorthite from India, first described in 1802 by Count Bournon.

3. *Amphodelite* is a reddish-gray or dingy peach-blossom-red variety, partly in rather large crystals, from Finland and Sweden; the angle between the two cleavage surfaces (or *O* ∧ *i*-ĭ) is 94° 20′, and *O* on edge *I*/*I′*=116°. *Lepolite* of Breithaupt (or, as he says, of von Jossa, who sent it to him) comes from the same region, and is the same variety; some of the crystals are 2 inches long

Latrobite, from Labrador, is pale rose-red, and closely resembles amphodelite. It has three cleavages, affording, according to Brooke, the mutual inclinations 98° 30′, 93° 30′, and 91°, or, according to Miller, 101° 45′, 93° 30′ (= *O* ∧ *i-ī*), and 109° (= *O* ∧ *I′*). Named after Rev. C. J. Latrobe.

Walmstedt's "Scapolite from Tunaberg" is anorthite, according to G. Rose (Kryst. Ch. Min., 83).

Comp.—O. ratio 1 : 3 · 4; $(\frac{1}{4}\dot{R}^3+\frac{3}{4}\dddot{Al})^2\ddot{Si}^3$=Silica 43·1, alumina 36·9, lime 20·0=100.

^{a} With Ca O and Ni O. ^{b} With Mn^2O^3.

Anal. 23, granular, in dioryte; 24, with hornblende forming a rock; 26, in dioryte, G.=2·77; 27, from meteorite of Juvenas.

Genth obtained in an analysis of his *Thiorsauite*, which is regarded as the same mineral as that of anal. 6, $\ddot{Si}$ 48·36, $\dddot{Al}$ 30·59, $\dddot{Fe}$ 1·37, $\dot{Mn}$ *tr.*, $\dot{Mg}$ 0·97, $\dot{Ca}$ 17·16, $\dot{Na}$ 1·13, $\dot{K}$ 0·62=100·20. The Neurode feldspar (anal. 19), from a serpentine rock, gives the O. ratio 1 : 2½ : 4, and is hydrous, and had probably lost part of its alumina. For an analysis of the same by v. Rath, see Pogg., xcv. 553.

Pyr., etc.—B.B. fuses at 5 to a colorless glass. Anorthite from Mt. Somma, and indianite from the Carnatic, are decomposed by muriatic acid, with separation of gelatinous silica.

Obs.—Occurs in some granites; occasionally in connection with gabbro and serpentine rocks; in some cases along with corundum; in many volcanic rocks.

Anorthite (*christianite* and *biotine*) occurs at Mount Vesuvius in isolated blocks among the old lavas in the ravines of Monte Somma, associated with sanidin, augite, mica, and idocrase; on the island of Procida near the entrance to the bay of Naples; in the Faroe islands, and on Java; on Iceland, on the plain of Thiorsà, Hecla, and elsewhere (G.=2·69—2·75); near Bogoslovsk in the

Ural (G.=2·72—.73, anal. 23, 24); at Carlingford in Ireland; in the meteoric stone of Juvenas (anal. 27).

Amphodelite occurs in Lojo, Finland, in a limestone quarry, and at Tunaberg, Sweden; *lepolite*, at Lojo and Orrijärfvi; *linseite* is probably the same partly altered (Breith., J. pr. Ch., xlvii. 236), containing a few p. c. of water. *Latrobite* is from Amitok island, on the coast of Labrador. *Indianite* is the gangue of corundum in the Carnatic, with garnet, cyanite, and hornblende; the specimen analyzed by G. J. Brush was originally from the hands of Count Bournon, and came from the Indian locality.

Anorthite was named in 1823 by Rose from ἀνορθός, *oblique*, the crystallization being triclinic. Bournon's name, *Indianite*, derived from the locality in India, was first published in his Catalogue of the Royal Mineralogical Collection, in the year 1817. The species had been described by him as early as 1802 (l. c.), and his description is remarkably complete for the time, it including, besides physical characters, a chemical analysis by Chenevix (anal. 1 above) agreeing nearly in essential points with the later by Rose, and quite as well as his, with the true or normal composition of the mineral. Bournon supposed that the grains might be rhombohedral in crystallization; but Brooke, in Phillips' Mineralogy (3d ed.), published in 1823, the year of Rose's publication, announced that there were two cleavages, inclined to one another 84° 45′ and 95° 15′, differing not widely from the same angle ($O \wedge i\text{-}\bar{i}$) as ascertained by Rose. Justice seems to require that Bournon's name should be restored to the species. Beudant, in the first edition of his mineralogy, published in 1824, describes indianite in full and called it lime-feldspar, mentioning anorthite only in his index.

Christianite was named by Monticelli and Covelli after the prince Christian Friedrick of Denmark, who explored Vesuvius with them; *Amphodelite* from ἀμφί, *double*, and ὀβελός, *spear*, the crystals being often twinned parallel to $i\text{-}\bar{i}$; *Latrobite*, after C. F. Latrobe, the discoverer of the variety.

For recent observations on cryst., see Descl. Min., i. 294; Hessenb. Min. Not., No. i. 6; Websky, ZS. G., xvi. 530; Kokscharof, Bull. Ac. St. Pet., vii. 326. The angles given are from Kokscharof, whose measurements agree closely with those of Marignac.

Alt.—*Linseite* N. Nordenskiöld, Komonen, Verh. Min. Ges. St Pet., 1843, 112. Considered altered lepolite, which is from the same mine in Orrijärvi, Finland. Occurs in large crystals, H.=3·5; G.=2·796—2·83; color black externally. The name is sometimes written *lindsayite*.

Sundvikite A. E. Nordenskiöld, Beskrifn. Finl. Min., 113, 1855, and Jahrb. Min., 1858. Feldspar-like in form; G.=2·70; from Nordsundvik, Finland. It is regarded as altered anorthite.

Rosite and *polyargite* are pinite-like pseudomorphs; see PINITE.

The following are analyses of these minerals: 1, Komonen (l. c.); 2, Hermann (J. pr. Ch., xlvi 393, xlviii. 254); 3, Bonsdorff & Ursin (Ramm. Min. Ch., 593):

	$\ddot{Si}$	$\bar{Al}$	$\bar{Fe}$	$\dot{Fe}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$
1. *Linseite*	47·50	35·29	—	7·03	3·56	—	—	—	6·62=100 Komonen.
2. "	42·22	27·55	6·98	2·00	8·85	—	2·58	3·00	7·00=100·13 Hermann.
3. *Sundvikite*	44·82	30·70	—	3·69	1·48	6·81	6·78	—	3·38, Mn 1·21=99·21 B. & U.

The presence of little lime and of much water is a peculiarity of each of these minerals.

310A. CYCLOPITE *von Waltershausen*, Vulk. Gest., 292, 1853. Cyclopite occurs in white transparent glassy crystals, with H.=6. According to v. Waltershausen, in crystallization it is triclinic, like anorthite and labradorite. Analysis afforded him (l. c.) $\ddot{Si}$ 41·45, $\bar{Al}$ 29·83, $\bar{Fe}$ 2·20, $\dot{Ca}$ 20·83, $\dot{Mg}$ 0·66, $\dot{Na}$ 2·32, $\dot{K}$ 1·72, $\dot{H}$ 1·91=100·92. It coats geodes in the doleryte of the Cyclopean islands near Catania.

310B. BARSOWITE *G. Rose*, Pogg., xlviii. 567, 1839. Massive, of a granular texture, with a nearly perfect cleavage in one direction.

H.=5·5—6. G.=2·74—2·752. Lustre more or less pearly. Color snow-white, subtranslucent. Fracture granular or splintery. Optically biaxial (Descl.).

Mean of three analyses by Varrentrapp (Pogg., xlviii. 568): $\ddot{Si}$ 48·71, $\bar{Al}$ 33·90, $\dot{Mg}$ 1·54, $\dot{Ca}$ 15·29=99·44. The analysis corresponds to the oxygen ratio 1 : 3·18 : 5·24. B.B. alone, fuses only on the edges to a vesicular glass. Gelatinizes easily on heating with muriatic acid. The mineral is probably identical with anorthite. Optical characters separate it from scapolite. Occurs in boulders in the auriferous sand of Barsovskoi, as the gangue of the blue corundum, as indianite is the gangue of the corundum of the Carnatic.

310C. BYTOWNITE *Thomson*, Min., i. 372, 1836. Bytownite is a greenish-white, feldspar-like mineral, occurring in boulders at Bytown, Canada, having G.=2·801, Thomson, 2·733, Hunt. It has been referred to anorthite, although the analyses give the oxygen ratio nearly 1 : 3 : 5, as in barsowite. The following are analyses with others of related substances: 1, Thomson (l. c.); 2, T. S. Hunt (Am. J. Sci., II. xii. 213, Phil. Mag., IV. i. 322); 3, Tennant (Rec. Gen. Sci., iii 389): 4, 5, T. S. Hunt (Logan's Rep., 1863, 479); 6, T. Thomson (Min., i. 384, 1836):

		$\ddot{Si}$	$\bar{\bar{Al}}$	$\bar{\bar{Fe}}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Na}$	$\dot{H}$
1. *Bytownite*	(?)	47·57	29·65	3·57	0·40	9·06	7·60	1·98=99·83 Thomson.
2. "		47·40	30·45	$\dot{Fe}$ 0·80	0·87	14·24	2·82	2·00, $\dot{K}$ 0·38=98·96 Hunt.
3. Bytown		45·80	26·15	$\dot{Fe}$ 4·70	2·95	16·25	—	2·00=97·85 Tennant.
4. Yamaska		46 90	31·10	1·35	0·65	16·07	1·77	1·00, $\dot{K}$ 0·58=99·42 Hunt.
5. Hunterstown		49·10	26·80	0·80	*tr.*	14·67	*und.*	1·30=98·96 Hunt.
6. *Huronite*		45·80	33·92	$\dot{Fe}$ 4·32	1·72	8·04	—	4·16=97·96 Thomson.

The specimen for anal. 2 was a greenish-white feldspathic rock from a boulder near Ottawa, having G.=2·73—"a portion of the specimen upon which Dr. Thomson based the species *bytownite*." That of 3 was from the same region, but is not called bytownite by Tennant. That of 4 was a feldspar from the intrusive dioryte of Yamaska mountain, having the cleavage surface finely striated; and associated with hornblende and a little sphene; G.=2·756—2·763. That of 5 is a pale sea-green feldspar from a boulder; G.=2·695—2·708.

Thomson's *huronite*, anal. 6 (l. c.), is an impure anorthite-like feldspar, related to the above, according to T. S. Hunt (priv. contrib.); excluding the 4·16 p. c. of water, the $\ddot{Si}$ would be 47 p. c. of the remainder. Thomson states that it is infusible. He also says that his bytownite is infusible, which Prof. Brush finds is not a fact.

311. **LABRADORITE.** Labradorstein (under Feldspat) *Wern.*, Ueb. Cronst., 149, 1780, Bergm. J., 375, 1789. Pierre de Labrador *Forst.*, Cat., 82, 1780; *de Lisle*, Crist., ii. 497, 1783. Labrador Feldspar. Labrador *G. Rose*, Gilb. Ann., lxxiii. 173, 1823; *Breith.*, Char., 1823. Lime Feldspar.

Mornite *Thom.*, Ed. N. Phil. J., xiii. 1832. Silicite *Thom.*, Phil. Mag., III. xxii. 190, 1843. Saussurite pt. Radauit *Breith.*, B. H. Ztg., xxv. 87.

Triclinic. Observed planes: O; $i\text{-}\breve{i}$; 1, I; $2\text{-}\bar{i}$; 1′, I'.

$I \wedge I' = 121°\ 37'$ $O \wedge I' = 113°\ 34'$ $i\text{-}\breve{i} \wedge I = 117°\ 30'$
$O \wedge i\text{-}\breve{i}$, ov. $2\text{-}\breve{i}'$, $= 93\ 20$ $O \wedge 2\text{-}\bar{i} = 98\ 58$ $i\text{-}\breve{i} \wedge I' = 120\ 53$
$O \wedge i\text{-}\breve{i}$, ov. $2\text{-}\breve{i}$, $= 86\ 40$ $O \wedge 1 = 125\ 28$ $i\text{-}\breve{i}$, left, $\wedge\ 2\text{-}\bar{i} = 90\ 20$
$O \wedge I = 110\ 50$ $O \wedge 1' = 122\ 42$ $I \wedge I$, in twin, $= 125$

Angles from Marignac. Rensch gives, as a mean of many measurements, $O \wedge i\text{-}\breve{i} = 86°\ 20'$, $O \wedge I' = 114°\ 4'$, $i\text{-}\breve{i} \wedge I' = 120°\ 43'$. Twins: (1) composition-face $i\text{-}\breve{i}$; often lamellar from repeated composition of this kind; (2) O, with the orthodiagonal as the axis of revolution. Cleavage: O easy; $i\text{-}\breve{i}$ less so; I traces. Also massive granular, and grains cleavable; sometimes cryptocrystalline or hornstone-like.

H.=6. G.=2·67—2·76. Lustre of O pearly, passing into vitreous; elsewhere vitreous or subresinous. Color gray, brown, or greenish; sometimes colorless and glassy; rarely porcelain-white; usually a change of colors in cleavable varieties. Streak uncolored. Translucent—subtranslucent.

Comp., Var.—O. ratio 1 : 3 : 6; $\dot{R}\ddot{Si}+\bar{\bar{Al}}\ddot{Si}^2$; or $(\frac{1}{3}\dot{R}^3+\frac{2}{3}\bar{\bar{Al}})^2\ddot{Si}^3+\frac{2}{3}\ddot{Si}$; =, if $1\dot{R}=\frac{3}{4}\dot{Ca}+\frac{1}{4}\dot{Na}$, Silica 52·9, alumina 30·3, lime 12·3, soda 4·5=100.

Var. 1. *Cleavable.* (*a*) Well crystallized to (*b*) massive.

Play of colors either wanting, as in some colorless crystals; or pale; or deep; blue and green are the predominant colors; but yellow, fire-red, and pearl-gray also occur. By cutting very thin slices parallel to $i\text{-}\breve{i}$ from the original labradorite, they are seen under the microscope to contain, besides striæ, great numbers of minute scales, like the aventurine oligoclase, which are probably göthite or hematite. The chatoyant colors may be heightened in their effect by these scales, but are not due to them (p. 336).

2. *Compact massive*, or *cryptocrystalline*; *Labradorite-Felsite.* The color sometimes gray to brownish-red; but sometimes porcelain-white. Some of the so-called *saussurite* is here included.

A variety from the gabbro of Baste in the Radau valley, Harz, is called *Radauite* by Breithaupt. Breithaupt refers to anal. 20; H.=5; G.=2·766—2·840; color white to gray; intercleavage angle 93½°. He also refers here, with a query, a feldspar from Rizzoni in the Tyrol; G. of a specimen not fresh 2·811.

In anal. 2, G.=2·646; anal. 5, from doleryte, of meteoric origin; anal. 6, G.=2·666; 8, G.=2·[illegible] 9, G.=2·709, trap, ywh.; 10, G.=2·71, brown, massive; 11, G.=2·72, with blue opalescence; 12, G.=2·72; 13, G.=2·68, between Lund and Christianstadt; 14, G.=2·715, hypersthene rock, bh.-gy.; 15, G.=2·707, gabbro, bh.-gy.; 16, O. ratio 1 : 2½ : 4½ or 1½ : 3½ : 6, gabbro, 17, G.=2·998, color porcelain-white; 18, snow-white, gnh.-w., little lustre, strp. with uralite; 19, in "melaphyre," between Botzen and Collman, pale gyh.-gn.; 20, G.=2·817, gabbro; 21, G.=2·[illegible] in porphyryte, 22, from gabbro; 23, ib., massive; 25, G.=2·883, in "porphyry," Southern Morea 27, G.=2·618; 28, G.=2·633; 29, G.=2·697, lavender-blue cleavable feldspar, from a boulder

30, G.=2·684—2·695, bluish opalescent, cleavable; 31, G.=2·67, bh.-white, in trap rock; 32, G.=2·68, pale bh.- or gnh.-gy., lustre of cleavage surfaces vitreous, elsewhere waxy; 33, G.=2·73—2·74, from basalt; 34, in trachytic doleryte, central peak; 35, glassy colorless crystals; 36–40 fr. Hungary, in trachyte; 36, G.=2·636; 38, G.=2·598; 39, G.=2·678; 40, G.=2·637. Anal. 36–39 give the O. ratio 1 : 3 : 7, intermediate between labradorite and andesite.

Pyr., etc.—B.B. fuses at 3 to a colorless glass. Decomposed with difficulty by muriatic acid, generally leaving a portion of undecomposed mineral.

Obs.—Labradorite is a constituent of some rocks. (1) The cleavable mineral, along with hornblende, composes a granite-like variety of *diabase*, or a rock resembling dioryte, but having labradorite as the feldspar. (2) If the hornblendic constituent is a dark *lamellar* variety of either hornblende or pyroxene, or the species hypersthene, the rock is called *hyperyte* (or hypersthenyte). (3) If the hornblendic mineral is a light lamellar pyroxene (diallage), the rock is called gabbro. (4) If the hornblende and labradorite constitute a homogeneous fine-grained compact mass, the rock is called *amphibolyte* or *diabase*; and (5) if the diabase contains distinct crystals of porphyry, it is a *diabase porphyry*, the green porphyry or oriental verd-antique of Greece (anal. 25) being of this nature. (6) The crypto-crystalline, or felsite variety of labradorite, occurring occasionally in connection with some of these rocks, has been called incorrectly *saussurite* and *jade* or *nephrite*. The above are labradoric metamorphic rocks.

There are also the following *labradoric intrusive* rocks. (7) *Doleryte*, consisting of labradorite and pyroxene, with generally some magnetite—a rock which, on the one hand, may be light-colored crystalline or granitoid, and on the other, dark-colored compact massive, either porphyrite or not, sometimes crypto-crystalline, and also a cellular lava; it includes much of the so-called *trap*, *greenstone*, and *amygdaloid*. (8) *Basalt*, similar to doleryte in structure, colors, and varieties, but containing, in addition to labradorite and pyroxene, chrysolite in disseminated grains. Doleryte and basaltic lavas are the most common of volcanic rocks. (9) Labradorite also occurs in other kinds of lava, and is sometimes found in them in glassy crystals, as in those of Etna and Vesuvius.

The labradoric metamorphic rocks are most common among the formations of the Azoic or pre-Silurian era. Such are part of those of British America, northern New York, Pennsylvania, Arkansas; those of Greenland, Norway, Finland, Sweden, and probably of the Vosges. Being a feldspar containing comparatively little silica, it occurs mainly in rocks which include little or no quartz (free silica).

Many foreign localities are mentioned above.

On the coast of Labrador, labradorite is associated with hornblende, hypersthene, and magnetite. It is met with in place at Mille Isles, Chateau Richer, Rawdon, Morin, Abercrombie, and elsewhere, in Canada East; and in boulders at Drummond and elsewhere, Canada West. It occurs abundantly at Essex Co., N. Y.; large boulders are met with in the towns of Moriah, Newcomb, M'Intyre, Westport, and Lewis, N. Y.; also occasionally in Orange, Lewis, St. Lawrence, Warren, Scoharie, and Green Cos. In Pennsylvania, at Mineral Hill, Chester Co., and opposite New Hope, Bucks Co.; in the Witchita Mts., Arkansas.

Silicite and *mornite* are from Antrim, Ireland.

Labradorite was first brought from the Isle of Paul, on the coast of Labrador, by Mr. Wolfe, a Moravian missionary, about the year 1770, and was called by the early mineralogists Labrador stone (*Labradorstein*), and also chatoyant, opaline, or Labrador feldspar. Klaproth's analysis above (No. 1) was the first one made (in 1815).

Labradorite receives a fine polish, and owing to the chatoyant reflections, the specimens are often highly beautiful. It is sometimes used in jewelry.

Alt.—Labradorite, like anorthite, appears to undergo alteration with considerable facility, it losing lime through infiltrating carbonated or alkaline waters, and receiving water. In some cases, also, it has received considerable iron. The following analyses appear to be of specimens of this altered labradorite. The results are remarkable for either the small proportion of *lime* or large proportion of *iron*, or the same of *potash* or of *water*, each of which may be regarded as an indication of alteration. Analyses: 1–4, Delesse (1, Ann. d. M., IV. xii. 200; 2, ib., xvi. 342; 3, Ann. Ch. Phys., III. xl. 271; 4, Ann. d. M., IV. xvi. 324); 5, Metzger (Jahrb. Min., 1850, 683); 6, v. Rath (ZS. G., ix. 246); 7, Delesse (Ann. d. M., IV. 512); 8, T. S. Hunt (Rep. G. Can., 1863, 479):

No. 1 is from a porphyritic rock, G.=2·719; 2, from dioryte; 3, the *vosgite*, from a porphyry G.=2·771, color whitish, sometimes slightly greenish or bluish, lustre greasy or pearly, 4, from the euphotide of Odern in Elsace; 5, from an altered diabase-porphyry; 6, from a gabbro, and remarkable for its high specific gravity, G.=2·840; 7, from a porphyritic amygdaloid, a colorless and translucent variety, with G.=2·642; 8, from a basalt (or chrysolitic doleryte), "with a small admixture of augite." Labradorite also occurs changed to calcite (Tschermak).

Artif.—Hausmann (Beitr. Eisenhochofenschlacken, 31) has referred to labradorite crystals distributed through the mass of the slag of a furnace at Veckeshagen, which were an inch long, but not well formed; had two cleavages at right angles to one another, with H.=6, G.=2·35; was fusible B.B., but insoluble in muriatic acid; and afforded S̈i 66·2, Ä̶l 10·4, Ċa 21·0, Ḟe 1·9, Ṁn 0·1=99·6.

Globules of the Variolyte of Durance. These concretionary globules are often half an inch or more in diameter, grayish-green in color, compact in texture, with G.=2·923. A specimen from a locality south of Mt. Genèvre, near Briançon, afforded Delesse (Ann. d. M., IV. xvii. 116):

S̈i	Ä̶l	F̶̈e	C̶̈r	M̶̈n	Ṁg	Ċa	Ṅa	K̇	ign.
56·12	17·40	7·79	0·51	*tr.*	3·41	8·74	3·72	0·24	1·93=99·86

Carnatite. A feldspar, described by Beudant, occurring at the localities of corundum and indianite in the Carnatic, India, is pronounced by Breithaupt and von Kobell to be labradorite.

312. ANDESITE. Andesin *Abich*, Jahresb., xxi. 167, 1841. Pseudoalbit. Saccharit *Glocker*, J. pr. Ch., xxxiv. 494, 1845.

Triclinic. Approximate angles from Esterrel crystals (Descl.): *O* ∧ *i-ĭ*, left, 87°–88°, *O* ∧ *I*=111°–112°, *O* ∧ *I'*=115°, *I* ∧ *i-ĭ*=119°–120°, *I'* ∧ *i-ĭ*= 120°, *O* ∧ 2-ī=101°–102°. Twins: (1) composition-face *i-ĭ*; (2) double twins, made up of two twins of the kind in (1), one of them reversed, so that there are 4 planes *I* in front, and at each end there are the planes O and 2-ī; (3) double twins, like the last, but one of the parts turned around, so that there are reëntering angles between two faces *O* and two *i-ĭ*, and four planes *I* in front. Cleavage more uneven than in albite. Also granular massive.

H.=5–6. G.=2·61—2·74; from the Andes, 2·61—2·74; of saccharite, 2·66—2·69; from the Vosges, 2·65—2·68; 2·668, Canada, Hunt. Color white, gray, greenish, yellowish, flesh-red. Lustre subvitreous, inclining to pearly.

Comp.—O. ratio 1 : 3 : 8, but varying to 1 : 3 : 7. Perhaps only a mixture of labradorite with a soda-feldspar. Formula $(\frac{1}{4}(\dot{Ca}, \dot{Na})^3+\frac{3}{4}\dddot{Al})^2 \ddot{Si}^3+3\ddot{Si}$; or with half the excess of silica basic.

Analyses: 1, Abich (Pogg., li. 523); 2, 3, Rammelsberg (5th Suppl., 48); 4, Jacobson (Ramm. Min. Ch., 607); 5, Deville (Ann. Ch. Phys., III. xl. 283); 6–9, Delesse (Mem. Soc. d'Em. du Doubs, Ann. d. M., V. iii. 374); 10, Varrentrapp (Pogg., lii. 473); 11, Schmidt (Pogg., lxi. 385); 12, Waltershausen (Vulk. Gest., 24); 13, Laspeyres (ZS. G., xviii. 329); 14, 15, v. Rath (ZS. [a] Probably some mixed quartz.

In anal. 1, G.=2·733; 2, G.=2·674; 3, G.=2·68–2·688; 4, G.=2·679; 5, G.=2·61; 6, from Servance, G.=2·683; 7, fr. Coravillers, G.=3·651; 8, G.=2·736; 12, G.=2·65; 14, "tonalyte," fr. Tyrol, G.=2·695; 15, G.=2·676; 16, G.=2·688; 18, lavender-blue, subtransp., cleavable, curved surfaces; 19, gnh. base of preceding, granular; 21, in a boulder; 22, G.=2·687; 23, G.=2·585; 25, G.=2·853; 26, G.=2·607; 27, in dioryte, G.=2·69. Other analyses: v. Rath, ZS. G., ix. 259.

Of these analyses all but No. 5, by Deville, afford rather closely the oxygen ratio 1 : 3 : 8. No. 5 gives 0·80 : 3 : 8·91. Nos. 24 to 26 have part of the alumina replaced by iron, and probably in consequence of alteration, as the black color, little soda, and much potash would indicate.

Pyr., etc.—Andesite fuses in thin splinters before the blowpipe. Saccharite melts only on thin edges; with borax forms a clear glass. Imperfectly soluble in acids.

Obs.—Occurs in the Andes, at Marmato, as an ingredient of the syenite-like rock called *andesyte*; in the porphyry of l'Esterel, Dept. of Var, France; in the syenite of Alsace in the Vosges; white at Servance, red at Coravillers; in the porphyry near Chagey, Haute Saône; at Hafnefiord, Iceland, in honey-yellow transparent crystals (anal. 12); at Baumgarten in Silesia (anal. 10); in the Tyrol, south of Tonale, in Mt. Adamello, in a granite-like rock called *tonalyte*, consisting of this feldspar, according to v. Rath, with much quartz, some orthoclase, biotite, and hornblende.

Saccharite is granular massive, with traces of cleavage in one direction, occurring in veins in serpentine at the chrysoprase mines near Frankenstein, in Silesia.

In North America, found at (Château Richer, Canada (anal. 16–20), forming with hypersthene and ilmenite a wide-spread rock; color flesh-red.

Alt.—The following are analyses of altered andesite in addition to 24 to 26 above: 1, Rammelsberg (Min. Ch., 608); 2–4, Deville (Bull. Geol. Fr., II. vi. 410); 5, Francis (Pogg., lii. 471). No. 2 is of the mass of a crystal, 2A of the interior, 2B of the exterior portion:

	$\ddot{\mathrm{Si}}$	$\overset{\dots}{\mathrm{Al}}$	$\overset{\dots}{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1. Esterrel Mts.	58·32	26·52	——	0·11	8·18	5·27	2·36	0·60=101·36 Ramm.
2. "	59·07	26·67	——	0·58	7·96	4·95	*tr.*	0·77=100 Deville.
2A. "	57·01	28·05	——	0·39	7·53	5·47	0·12	1·43=100 Deville.
2B. "	52·42	24·78	——	0·51	15·02	5·10	0·14	2·05=100 Deville
3. Hungary	58·92	26·69	1·20	1·68	6·98	4·02	1·20	1·40, $\ddot{\mathrm{C}}$ 2·93=100·02 Deville.
4. Marmato	58·11	28·16	——	1·52	5·35	5·17	0·44	1·25=100 Deville, G.=2·62.
5. Popayan	56·72	26·52	0·70	——	9·38	6·19	0·80	——=101·31, Francis; G.=2·64.

The oxygen ratio for 1 is 1 : 3 : 7·5; 2, 0·9 : 3 : 7·5; 2A, 0·84 : 3 : 7·0; 2B, 1·5 : 3 : 7·3; 3, 0·9 : 3 : 6·9; 4, 0·8 : 3 : 7·2; 5, 1 : 3 : 7·2. The mineral of the Esterrel Mts., near Fréjus in southern France, occurs in a rock called porphyry. Deville's analyses leave no doubt as to the alteration. The analysis by v. Rath (No. 14, above) also gives nearly the ratio 1 : 3 : 7; and the next, 1 : 3 : 7½. No. 4, from Marmato, contains 1·4 p. c. of carbonate of lime.

Deville takes the ground, as a result of his analyses, that all andesite is altered *oligoclase*, the oxygen ratio of which is 1 : 3 : 9; and the same result was earlier suggested by G. Rose and Bischof. Deville's analyses of the Marmato andesite gave him nearly the oligoclase ratio.

Andesite changes also to *kaolin*. That of La Bresse, studied by Delesse, is in part in thi condition, being soft and crumbling; and in part less changed and of a reddish color.

313. HYALOPHANE. Hyalophan *v. Waltershausen*, Pogg., xciv. 134, 1855, c. 548.

Monoclinic, like orthoclase, and angles nearly the same. Observed planes: *O*; vertical planes, *I*, *i-ì*, *i-3*; hemidomes, 1-*i*, ⅔-*i*; clinodome, 2-ì *C* (by calc.)=64° 16′ *I* ∧ *I*=118° 41′, *I* ∧ *i-ì*=120° 36′, *O* ∧ 1-*i*=130° 55½′, *I* ∧ 1-*i*=111° 55′. Cleavage: *O* perfect, *i-ì* somewhat less so. In small crystals, single, or in groups of two or three.

H.=6–6·5. G.=2·80, transparent; 2·905, translucent. Lustre vitreous, or like that of adularia. Color white, or colorless; also flesh-red. Transparent to translucent.

Comp.—O. ratio for $\dot{R}$, $\bar{\bar{R}}$, $\ddot{S}i$=1 : 3 : 8; formula $(\frac{1}{4}(\dot{B}a, \dot{K})^3+\frac{3}{4}\bar{\bar{A}}l)^2\ddot{S}i^3+3\ddot{S}i$, or like andesite and leucite, except that the protoxyds are mainly baryta and potash.

Analyses: 1, Uhrlaub (Pogg., c. 548); 2, same, the impurity, sulphuric acid and part of baryta as sulphate, being removed; 3, Stockar-Escher (Kenng. Uebers. 1856–57, 107); 4, Petersen (Jahrb. Min. 1867, 102); Igelström (Œfv. Ak. Stockh. 1867, J. pr. Ch., ci. 434):

	$\ddot{S}i$	$\bar{\bar{A}}l$	$\dot{M}g$	$\dot{C}a$	$\dot{B}a$	$\dot{N}a$	$\dot{K}$	$\dot{H}$	$\dddot{S}$	
1. Binnen	45·65	19·14	0·73	0·77	21·38	0·49	8·23	0·54	4·12	=101 Uhrlaub.
2. "	51·30	21·50	0·84	0·87	15·11	0·55	9·25	0·58	——	=100 Uhrlaub
3. "	52·67	21·12	0·04	0·46	15·05	2·14	7·82	0·58	——	=99·88 St.-E.
4. "	51·84	22·08	0·10	0·65	14·82	10·03		0·48	——	=100 Petersen
5. Jakobsberg, Swed.	51·14	22·86	3·10	4·28	9·56	[9·06]		——	——	=100 Igelstr'm

Anal. 2 gives the O. ratio 1 : 2·6 : 7, and 3, 1 : 2·8 : 7·8; and 4 agrees well with No. 3. No. 5 contains less baryta and more lime.

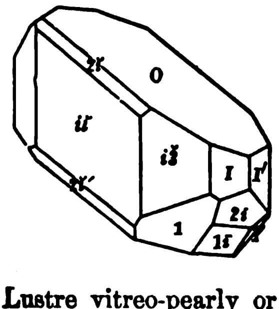
Pyr., etc.—B.B. fuses with difficulty to a blebby glass. Unacted upon by acids.

Obs.—Occurs in a granular dolomite, along with white barite, greenish tourmaline, mica, realgar, dufrenoysite, and sphalerite, near Imfeld, in the valley of Binnen in the Valais, in crystals 2 or three lines long, and rarely larger; also at the manganese mine of Jakobsberg in Sweden, in limestone with a manganiferous epidote (p. 288), looking much like common flesh-red orthoclase. A massive variety accompanies it, containing according to Igelström (l. c.) $\ddot{S}i$ 50·90, $\bar{\bar{A}}l$ 21·09, $\dot{C}a$ 13·30, $\dot{B}a$ 3·50, alkalies, $\dot{M}g$ and $\dot{M}n$, 11·21 undetermined.

314. OLIGOCLASE. Natron-spodumen *Berz.*, Arsb., 160, 1824=Soda-spodumene. Oligoklas *Breith.*, Pogg., viii. 79, 1826. Hafnefjordit, Kalkoligoklas, *Forchhammer*, Skand. Nat. samm i Stockholm, July, 1842. Aventurine Feldspar=Sunstone pt.

Triclinic. Observed planes (see, for position, the table under anorthite or albite): *O*; 2-ĭ, *i-ĭ*, 2-ĭ′; *i-5*; *i-3*; –2, *I*, 2, 1; 2-ī, ⅔-ī, 1-ī; –2′, *I*′, 2′, 1′; *i-3*′; *i-5̆*′.

299



I ∧ *I*′=120° 42′ *O* ∧ 1=123° 51′
O ∧ *i-ĭ*, ov. 2-ĭ′,=93 50 *O* ∧ 1′=121 15
O ∧ *i-ĭ*, ov. 2-ĭ,=86 10 *O* ∧ 1-ī=127 6
O ∧ *I*=110 55 *O* ∧ 2-ī, ov. 1-ī,=97 22
O ∧ *I*′=114 40 *i-ĭ* ∧ *I*′=120 24
O ∧ 2-ĭ′=136 23 *i-ĭ* ∧ *I*=118 54
O ∧ 2-ĭ=132 40 *I*′ ∧ *i-3*′=150 30
I ∧ *i-3*=147 30

Cleavage: *O*, *i-ĭ*, perfect, the latter least so. Twins: similar to those of albite. Also massive.

H.=6–7. G.=2·56–2·72; mostly 2·65–2·69. Lustre vitreo-pearly or waxy, to vitreous. Color usually whitish, with a faint tinge of grayish-green, grayish-white, reddish-white, greenish, reddish sometimes aventurine. Transparent, subtranslucent. Fracture conchoidal to uneven.

Comp., Var.—O. ratio 1 : 3 : 9; $(\frac{1}{4}(\dot{N}a, \dot{C}a)^3+\frac{3}{4}\,\dddot{A}l)^2\,\ddot{S}i^3+3\frac{3}{4}\,\ddot{S}i$; or else with half the excess of silica basic; =, taking $\dot{R}$ as soda alone, Silica 62·1, alumina 23·7, soda 14·2=100. Part of the soda is replaced by lime.

Var. 1. *Cleavable*; in crystals or massive.

2. *Compact massive*; *oligoclase-felsite*; includes part, at least, of the so-called compact feldspar or *felsite*, these consisting of the feldspar in a compact, either fine granular or flint-like state, containing free silica disseminated through the mass. In those here included, the feldspar is a soda-feldspar, and it is often difficult to distinguish them from *albite-felsite*. See under ALBITE for analyses.

3. *Aventurine oligoclase, or sunstone.* Color grayish-white to reddish-gray, usually the latter, with internal yellowish or reddish fire-like reflections proceeding from disseminated crystals of probably either hematite or göthite.

Much oligoclase has a faint greenish tinge and pearly lustre, in which it somewhat resembles spodumene, whence the name *soda-spodumene*. Only the oligoclase of lavas or trachytic rocks has G. below 2·6. *Hafnefiordite* (anal. 36) contains the protoxyds of an andesite or labradorite, and may not belong here.

4. *Moonstone* pt. A whitish opalescence.

Analyses: 1, 2, Berzelius (Jahresb., iv. 147, xix. 302); 3, L. Svanberg (Œfv. Ak. Stockholm, iii. 111); 4, R. A brownish feldspar from Borodin, Finland, afforded S. v. Waltershausen (Vulk. Gest., 26) $\ddot{\text{S}}$ 63·20, $\dddot{\overline{\text{Al}}}$ 18·41, $\dddot{\overline{\text{Fe}}}$ 0·20, $\dot{\text{Mg}}$ 0·87, $\dot{\text{Ca}}$ 0·11, $\dot{\text{Na}}$ 0·52, $\dot{\text{K}}$ 14·41, $\dot{\text{H}}$ 0·57=98·29. It may be an orthoclase. G.=2·583. No. 9 may be mainly *albite*, judging from the amount of soda.

In anal. 3, G.=2·69; 8, G.=2·656; 9, G.=2·63; 11, G.=2·656; 12, G.=2·65; 13, G.=2·631 16, G.=2·66—2·68, in mica schist; 17, G.=2·651; 19, G.=2·72, ign.=1·05; 24, G.=2·662; 28 G.=2·61; 31, G.=2·586, H.=7·5, granular with emery; 33, G.=2·594; 34, G.=2·58—2·59, in trachyte; 35, G.=2·592, in trachyte; 37, G.=2·56, in lava; 38, G.=2·635; 39, 40, in dioryte, G.=2·63—2·64; Nos. 1 to 31, in metamorphic rocks, granite, gneiss, porphyry, syenite, and dioryte; 32–37 in lavas or volcanic rocks.

Some of the analyses vary from the oxygen ratio 1 : 3 : 9 toward 1 : 3 : 12, and Scheerer in the Handw. Chem. of Liebig, Poggendorf, etc., makes intermediate varieties, shading into both albite and orthoclase, one called by him *oligoclase-albite*, the other *oligoclase-orthoclase*—see under *orthoclase* and *albite*. But as explained elsewhere, these probably arise from mixture.

Other analyses: from Ytterby, Haughton, Q. G. J., xviii. 412; from Dockweiler, in the Eifel, A. Streng, B. H. Ztg., xxiii. 53; from granite of the Ockerthal and of Meineckeburg, Fuchs, ib.

Pyr., etc.—B.B. fuses at 3·5 to a clear or enamel-like glass. Not materially acted upon by acids.

Obs.—Occurs in porphyry, granite, syenite, serpentine, and also in different eruptive rocks. It is sometimes associated with orthoclase in granite, or other granite-like rock. Among its localities are Danviks-Zoll near Stockholm; Kimito in Finland, forming with quartz and mica the granite containing columbite; Pargas in Finland; Ariége and Arendal, with calcite, epidote, etc., crystals sometimes 2 or 3 in. long; Schaitansk, Ural, greenish, in a gangue of quartz and mica and yellowish-white feldspar; in gneiss of the Schwarzwald of Goggenau, north-east of Baden; in syenite of the Vosges; in a micaceous dioryte (called *kersantyte*) at Visembach in the Vosges; in protogine of the Mer-de-Glace, in the Alps; in euphotide at Lavaldens, Department of Isère; at Albula in the Grisons; in a dark green porphyry at Quenast in Belgium; in mica schist at the Emerald Mine of the Urals, and at Boden near Marienberg; in the amphibolyte of Marienbad, Bohemia; in a green porphyry (oligoclase-porphyry of Rose), near Elbingerode in the Harz; in diabase of the Harz; the Fichtelgebirge; Chalanches in Allemont and Bourg d'Oisans; as *sunstone* at Tvedestrand in the Christiana-fiord, Norway; at Hitteröe, Lake Baikal; at the North Cape, near Hammerfest; in Donigal, Ireland, in granite, with orthoclase, etc.; in Iceland, colorless, at Hafnefjord (*hafnefiordite*). The oligoclase-porphyry is called *oligophyre* by Coquand; near St. Raphael in the Dept. of Var, in France, a rock of this kind has a beautiful turquois-blue color, is very hard, and encloses crystals of oligoclase; G.=2·61. In lavas and trachyte (*oligoclase-trachyte*) at Teneriffe, and in the Euganean Mts. near Padua; in the domyte (trachyte) of Puy de Dome; in doleryte at L. Laach; in pumice at Arequipa in Peru; in obsidian, with sanidin, at Zimapan in Mexico.

In the United States, at Unionville, Pa., with euphyllite and corundum, G.=2·61; also at Danbury, Ct., with orthoclase and danburite; Haddam, Ct., often transparent, with iolite and black tourmaline; Mineral Hill, Delaware Co., Pa., called moonstone; at Orange summit, N. Hamp., slightly greenish, and pearly; at the emery mine, Chester, Mass., granular, with H.=7·5, G.=2·586; at Dixon's quarry, Del.

Named in 1826 by Breithaupt from ὀλίγος, *little*, and κλάω, *to cleave*. Berzelius had previously (in 1824) recognized it as a new mineral from specimens from Danviks-Zoll; and he afterward named it natron-spodumene (soda-spodumene).

Alt.—Occurs altered to kaolin and natrolite. The change to kaolin takes place more easily than in orthoclase, as shown by the longer resistance of the latter when both occur in the same rock (Laspeyres, ZS. G., xvi. 387).

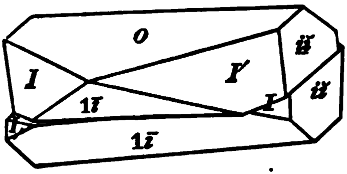
Cleavage: O, $i\text{-}\breve{i}$ perfect, the first most so; $1\text{-}\bar{i}$ sometimes distinct. Twins: 1. Composition-face $i\text{-}\breve{i}$, axis of revolution normal to $i\text{-}\breve{i}$, the most common,

f. 301. 2. C.-face and revolution the same, but (f. 307) the two halves by mutual penetration crossing along a medial vertical line, so that the right quarter in front is continued in the left quarter behind, and the left in front in the right behind, the upper and under planes *O* meeting in a reëntering angle, and the 2-ĭ on either side in a salient angle—making an intersecting twin, having the aspect of a double twin of four crystals in which the two diagonally opposite are alike in position. 3. C.-face the same, but axis of revolution *parallel* to *i*-ĭ, and vertical, producing the form in f. 304, the planes *O* and 1 above (or below) being very nearly in the same zone (the plane angle of *i*-ĭ, which the edges of *I* and *O* make, being 116° 26′, and that which the edges of *I* and 1 make being 115° 55′, differing only 31′); also exemplified in the double twin, f. 308, the two halves of which are twins like f. 307; may be right or left-handed, according to which half is revolved; also in other similar double twins (fr. Middletown, Ct.), in which the two halves are like f. 305. 4. C.-face parallel to *O*, and revolution on a horizontal axis normal to the shorter diagonal of *O*, as in f. 309; the twin right or left-handed, according as the part revolved is the upper or lower. 5. The last kind (4), combined with the first (1), making double twins. Also massive, either lamellar or granular; the laminæ sometimes divergent; granular varieties occasionally quite fine to impalpable.

309



Pericline.

H.=6–7. G.=2·59–2·65; 2·612, Finbo, Eggertz; 2·619, Broddbo. Lustre pearly upon a cleavage face; vitreous in other directions. Color white; also occasionally bluish, gray, reddish, greenish, and green; sometimes having a bluish opalescence or play of colors on *O*. Streak uncolored Transparent—subtranslucent. Fracture uneven. Brittle.

Comp., Var.—O. ratio 1 : 3 : 12; $(\frac{1}{2}\dot{N}a^{3}+\frac{2}{3}\dddot{A}l)^{2}\dddot{S}i^{3}+6\dddot{S}i$, or with half the excess of silica basic =Silica 68·6, alumina 19·6, soda 11·8=100. A small part of the soda is replaced usually, if not always, by potash, and also by lime. But these differences are not externally apparent.

Var. 1. *Ordinary*. (*a*) In crystals or cleavable massive. The angles vary somewhat, especially for plane *I′*; *I* ∧ *I′*=122° 15′, G. Rose; 121° 45′, Marignac and Descloizeaux, as mean of many measurements of St. Gothard crystals; *O* ∧ *I′*=115° 5′, Rose; 114° 52′, M. and D. (*b*) *Aventurine*, similar to aventurine oligoclase and orthoclase. (*c*) *Moonstone*; similar to moonstone under oligoclase and orthoclase. *Peristerite* is a whitish adularia-like albite, slightly iridescent, having G.=2·626; named from περιστερά, *pigeon*, the colors resembling somewhat those of the neck of a pigeon. (*d*) *Pericline* is in large, opaque, white crystals, short and broad, of the forms in fig. 308, 309. G.=2·641; *I* ∧ *I′*=120° 37′, Breith.; from the chloritic schists of the Alps.

(*e*) *Hyposclerite* is blackish-green, from Arendal; H.=5·5; G.=2·63–2·66; it contains, according to Rammelsberg, 5 p. c. of pyroxene. Hermann figures (J. pr. Ch., xlvi. 396) a crystal having the planes and nearly the form of f. 302. Named from ὑπό, *under*, σκληρός, *hard*, with reference to the inferior hardness.

(*f*) Lamellar; *cleavelandite*; a white kind found at Chesterfield, Mass., and named after Dr. P Cleaveland, the mineralogist.

2. *Compact*; *albitic felsite*; smooth on surface of fracture, whitish, grayish, or reddish-gray in color, and very tough. H.=6·5–7·5; G.=2·6–2·65. See also under OLIGOCLASE.

[a] As impurity, or mainly so.

In anal. 1, G.=2·61; 7, G.=2·624; 9, G.=2·595; 11, G.=2·612; 12, G.=2·478; 13, G = 2·63; 14, G.=2·624; 18, G.=2·61; 20, G.=2·619; 24, G.=2·633 Brush.

The *hyposclerite* (anal. 13) afforded Hermann (l. c.) $\ddot{\mathrm{Si}}$ 56·43, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 21·70, $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·75, $\bar{\mathrm{M}}\mathrm{n}$ 0·39, $\dot{\mathrm{Ce}}$, $\dot{\mathrm{La}}$ 2·60, $\dot{\mathrm{Ca}}$ 4·83, $\dot{\mathrm{Mg}}$ 3·39, $\dot{\mathrm{K}}$ 2·65, $\dot{\mathrm{Na}}$ 5·79=99·80, giving the abnormal and improbable O. ratio 1 : 2 : 6, which Rammelsberg's later analysis appears to show to be incorrect, or the composition of an altered form of it. Its inferior hardness would indicate alteration.

The albite from Pennsylvania, analyzed by Redtenbacher (anal. 19), is called *oligoclase-albite* by Scheerer; it gives the O. ratio 1·1 : 3 : 11·7. He applies the same name to the Snarum feldspar analyzed by Richter, which he says has the external form of scapolite, and G.=2·59; oxygen ratio 1 : 3 : 11·3. It is the *olafite*. That of Snarum, analyzed by Scheidtauer, was in snow-white crystals, and gave 1·2 : 3 : 11·8; it holds an excess of protoxyds, owing to the lime present, which may be a result of alteration.

Felsite or compact feldspar has usually some free silica disseminated through it. The following are analyses of some kinds, either *albite-felsite* or *oligoclase-felsite*. The presence of lime is in favor of the latter. *Adinole* is probably albitic; it is reddish, from Sala, Sweden. Amausite *Gerhard* has been considered as oligoclase in base; the name was given to a granulite (Weissstein) of Namiest in Moravia. The analysis here cited of the North Carolina mineral, by Genth, is in the Am. J. Sci., II. xxviii. 249:

	$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\ddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$

See under ORTHOCLASE for other felsites.

Pyr., etc.—B.B. fuses at 4 to a colorless or white glass, imparting an intense yellow to the flame. Not acted upon by acids.

Obs.—Albite is a constituent of several rocks. With hornblende it constitutes *dioryte* or

greenstone. It occurs with orthoclase in some granite, as in that of Pompey's Pillar
cases is usually distinguishable by its greater whiteness. It is common also in gneis
times in the crystalline schists. Veins of albitic granite are often repositories of the
minerals and of fine crystallizations of gems, including beryl, tourmaline, allanite. c
It occurs also in some trachyte, as that of Montagna, Island of Pantellaria; in phon
gafjall, Iceland; in granular limestone in disseminated crystals, as near Modane in S

In the compact condition, felsite, it constitutes the base of *albite porphyry*, a roc
red (as at Agay) with scattered whitish crystals of albite; also the same of some
Frejus, a compact grayish rock, containing globules of carbonate of lime, the base
cording to Diday, is 70 p. c. albite; also of some *granulyte* or *weissstein* (white stone)

Many localities of albite are mentioned above. It occurs with epidote and garne
with eudialyte and hornblende in Greenland.

In the United States, in *Maine*, at Paris, with red and blue tourmalines. In *Mas*
field, with the same minerals, in lamellar masses (cleavelandite), slightly bluish, also
and rarely in small crystals; at Goshen. In *New Hamp.*, at Acworth and Alstead.
Haddam, with chrysoberyl, beryl, columbite, and black tourmaline; at the Middlet
quarry, in fine transparent or translucent crystals (fig. 305); at Monroe, a fine gra
containing beryl. In *N. York*, at Granville, Washington Co., white transparent crysta
Essex Co., of a greenish color, with smoky quartz, and resembling green diallage.
Unionville, Delaware Co., a granular variety is the matrix of the corundum (see anal
having the hardness of quartz (7—7·25). It had been taken for indianite. A si
equally hard, is found with idocrase at Sanford, Maine. In *California*, Calaveras Co
gold and auriferous pyrites.

In Canada, in fine crystals, at the Suffield silver mine, near L. Massawippi, N.
phremagog.

The name *Albite* is derived from *albus*, white, in allusion to its color, and was give
by Gahn and Berzelius in 1814.

For recent observations on cryst., Descl. Min., i. 317; Hessenberg, Min. Not.,

Cleavage: *O* perfect; *i*-ì less distinct; *i*-*i* faint; also imperfect in the direction of one of the faces *I*. Twins: 1. Composition-face *i*-ì, axis of revolution normal to *i-ĭ*, the forms not showing the composition externally, except sometimes by sutures. 2. C.-face *i-ĭ*, axis of revolution vertical, producing, with the form in f. 310, the twins f. 314, 315, which are right- or left-handed, according as one or the other of the parts is the one revolved; with the form in f. 311, the planes 1-*ĭ* and *O* nearly coincide in the twin. 3. C.-face 2-*ĭ*, as in f. 321, in which the prism is made up of two adjoining planes *O* and two *i-ĭ*, and is nearly square, because *O* ∧ *i-ĭ*=90°, and *O* ∧ 2-*ĭ*=135° 3′; *I* ∧ *I*=169° 28′; also the same in a twin of 4 crystals, f. 317, each side of the prism then an *O*; same in a twin of 3 crystals, one of the four being absent, and that side of the prism made up of the planes *i-ĭ*, *i-ĭ*; again the twin of 4 crystals takes, by cross-interpenetration of each, the form in f. 322, consisting apparently of 8 crystals, or four twins of the kind in f. 321; *I* ∧ *I*=169° 28′, as above. 4. C.-face *O*, f. 316.

Often massive, granular; sometimes lamellar. Also compact crypto-crystalline, and sometimes flint-like or jasper-like.

H.=6–6·5. G.=2·44–2·62, mostly 2·5–2·6. Lustre vitreous; on cleavage-surface sometimes pearly. Color white, gray, flesh-red, common; greenish-white, bright green. Streak uncolored. Transparent to translucent. Fracture conchoidal to uneven. Optic-axial plane sometimes in the orthodiagonal section and sometimes in the clinodiagonal; acute bisectrix always negative, normal to the orthodiagonal; inclined at 18° C., in adularia, according to Angström, 4° 6′ to the clinodiagonal, and 112° 1′ to edge *I*/*I*; and according to Descloizeaux, at 22° C. these angles are 5° 18′ and 110° 49′ for the red rays; angle of divergence in adularia of St. Gothard 112° to 123°; in transparent from Wehr in the Eifel, only 18° to 21°, with other optical peculiarities.

Comp., Var.—O. ratio 1 : 3 : 12; $(\frac{1}{4}K^3+\frac{3}{4}\dddot{A}l)^2\ddot{S}i^3+6\ddot{S}i$; or else with half the excess of silica basic;=Silica 64·6, alumina 18·5, potash 16·9=100; with soda sometimes replacing part of the potash. The orthoclase of Carlsbad contains rubidium.

The varieties depend mainly on structure, variations in angles, the presence of soda, and the presence of impurities.

The amount of soda detected by analyses varies greatly, the ratio to the potash being from 1 : 100 to 1 : ½. But recent chemical investigations have shown, what Breithaupt indicated from ocular examination in 1861, that some of the sodiferous varieties owe the soda to a crystalline combination of the orthoclase with albite. The *perthite* (see beyond) has thus been found to consist of thin alternate layers of these two feldspars. How far this explanation extends to other sodiferous kinds remains to be ascertained.

The variations in angles are large, and they occur sometimes even in specimens of the same locality. In crystals of the kind called *chesterlite*, which are to all appearance regular and undistorted, the angle *I*′ (right prismatic plane) ∧ *I* (left id.) varies from 121° to 127°, according to the author's measurements; and other angles make the form *triclinic*, *O* ∧ *I* and *O* ∧ *I*′ sometimes differing 5°, one being 110° and the other 115°; while twins compounded parallel to the clinodiagonal section, which are common, prove, by the absence of any reëntering angle on the base, that the form is *not triclinic* (although so made by Breithaupt, who refers the species (B. H. Ztg., xvii. 1) to albite). The crystallization is normally monoclinic, and the variations are simply irregularities. There are also large optical variations in orthoclase, on which see Descl. Min., i. 329.

The variations in amount of soda and in angles have led Breithaupt to make several species out of the species orthoclase. But until it is proved that crystals of certain specific angles have uniformly the same specific chemical composition, and further, that kinds having the same specific chemical composition wherever occurring, always, when crystallized, present the same angles, such species cannot properly be recognized as distinct. The varieties that have been named are the following:

Var. 1. *Ordinary*. In crystals, or cleavable massive. (*a*) *Adularia*. Transparent, cleavable, usually with pearly opalescent reflections, and sometimes with a play of colors like labradorite, though paler in shade. *Moonstone* (Hecatolite *Delameth.*, T. T., ii. 201, fr. 'εκατη, *the moon*) belongs in part here, the rest being albite and oligoclase. *Valencianite*, from the silver mine of Valenciana Mexico, is adularia. Breithaupt finds for ordinary orthoclase (which he calls *pegmatolite*) G.$=2{\cdot}539-2{\cdot}578$ (B. H. Ztg., xxv. 38). Kokscharof obtained (Min. Russl., v. 115) from crystals from the Grisons, Switzerland, for $I \wedge I=118^\circ\ 48'\ 20''$; $O \wedge I$, acute, $=67^\circ\ 45'\ 50''-47'$; $O \wedge I$, obtuse, $=112^\circ\ 12'\ 20''-14'\ 10''$; $O \wedge 1\text{-}i=129^\circ\ 32'$. For crystals from Zillerthal, $I \wedge I=118^\circ\ 45\tfrac{1}{2}'-50'$ (mean, $118^\circ\ 47'\ 21''$); $O \wedge I$, acute, $=67^\circ\ 47'\ 20''-50'$ (mean, $67^\circ\ 47'\ 38''$); $O \wedge I$, obtuse, $=112^\circ\ 10'\ 20''-13'$ (mean, $112^\circ\ 12'\ 57''$); $O \wedge 1\text{-}i=129^\circ\ 43'\ 10''-50'$ (mean, $129^\circ\ 42'\ 38''$). He gives as the calculated results for adularia, $I \wedge I=118^\circ\ 47'$ and $61^\circ\ 13'$; $O \wedge I=67^\circ\ 47'\ 20''$ and $112^\circ\ 12'\ 40''$; $O \wedge 1\text{-}i=129^\circ\ 43'\ 26''$; $O \wedge 2\text{-}i=135^\circ\ 3'\ 39''$; $C\,(O \wedge i\text{-}i)=63^\circ\ 56'\ 46''$.

(*b*) *Sunstone*, or *aventurine feldspar* (Heliolite *Delameth.*, T. T., ii. 200). In part orthoclase; rest albite or oligoclase (q. v.).

(*c*) *Necronite*. A cleavable feldspar, fetid in odor when struck. The original was found by Hayden near the York and Lancaster road, 21 m. from Baltimore, in granular limestone, and was whitish or bluish in color. Named from νεκρός, *a corpse*.

(*d*) *Amazonstone*. Bright verdigris-green, and cleavable.

(*e*) *Erythrite*. Flesh-red, from amygdaloid, near Kilpatrick. Made out by Thomson to contain 3 p. c. of magnesia. Named from ἐρυθρός, *red*.

(*f*) *Sanidin* of Nose, or *glassy feldspar*, including much of the *Ice-spar*, part of which is anorthite. Occurs in transparent glassy crystals, mostly tabular (whence the name from σανίς, a board) in lava, pumice, trachyte, phonolite, etc. Proportion of soda to potash varies from 1 : 20 to 2 : 1. A. Mitscherlich finds in some kinds 0·79—2·33 p. c. of baryta. *Rhyacolite* is the same; the name was applied to glassy crystals from Mt. Somma (Eisspath *Wern.*). Rose has since observed (Kryst. Ch. Min., 88) that the specimen he analyzed (Pogg., xxviii. 143) probably contained some mixed nephelite, and that the mineral is *orthoclase*. Named from ῥύαξ, *stream* (lava stream), and λίθος, *stone*.

(*g*) *Chesterlite*. In white crystals, smooth, but feebly lustrous, implanted on dolomite in Chester Co., Penn., and having the variations in its angles above stated. It contains but little soda. Twins occur with composition parallel to O, and also parallel to both O and $i\text{-}i$, the latter apparent by the meeting of striæ along the middle of an O, and the former by the same on an $i\text{-}i$. Crystals vary from a line in breadth to 1½ in. G.$=2{\cdot}531$ Silliman. Erni's analysis (This Min., 3d edit., 1850, 678) is erroneous, and therefore not cited here.

(*h*) *Microclin*. Usually in cleavable masses, whitish, grayish, or reddish, and opalescent. The original was from the zircon-syenite of Fredericksvärn and Laurvig and Brevig, Norway. Breithaupt made the angle between the two cleavage planes $90^\circ\ 22'-90^\circ\ 23'$, instead of 90°; and hence derived the name, from μικρός, *little*, and κλίνω, *I incline*. The analysis (No. 55) gives for the ratio of $\dot{N}a$ to $\dot{K}$ 3 : 2. But Breithaupt has since referred to microclin the feldspar of Arendal, which afforded him the same angle, but yet contains but a trace of soda (No. 22). He also refers here a feldspar from Kangerdluarsuk, Greenland (anal. 54), which is near the first-mentioned in composition, and gave the angles $O \wedge i\text{-}i=90^\circ\ 22'$, $O \wedge I=112^\circ\ 9'$, $O \wedge I'=113^\circ\ 10'$, $O \wedge 1\text{-}\bar{i}=129^\circ\ 34'$, $i\text{-}i \wedge I'=119^\circ\ 13'$ $I \wedge I'=119^\circ\ 4'$, $I \wedge i\text{-}i=121^\circ\ 48'$; also the feldspar of the micaceous rock (called *Miascyte*) of Miask (Urals), which has Na : K$=1:1$, with an excess of silica, according to an unsatisfactory analysis; also a Bodenmais feldspar of gray and greenish colors, with G.$=2{\cdot}575-2{\cdot}594$, but he suggests that Kerndt's analysis (No. 56) was probably made on a mixture of microclin and oligoclase, the two occurring together; while Potyka found that the green variety (anal. 25) contained little soda. Potyka also states that the actual form was triclinic, and that the cleavage face had the usual striæ of triclinic feldspars; but Kenngott observes (Ueb., 1861, 73) that he did not find the striæ on a Bodenmais specimen, and H. Fischer none on the feldspar of the zircon-syenite. Other loc. reported by him are: Lewis Co., N. Y., with black pyroxene; Baveno in Italy; Lomnitz and Fischbach in Silesia, of red color; Scholtzenberg and Kunersdorf, Silesia; Olbern-hau in Silesia, grayish-white, G.$=2{\cdot}593$; Sforzella in Predazzo, white, G.$=2{\cdot}596$; syenite of the Plauen-Grund, near Dresden—an extension of its distribution which must make it easy to test the value of its distinctive characters.

Notwithstanding the measurements of Breithaupt, microclin is probably monoclinic. Descloizeaux, after optical investigations (Min., i. 341), refers it to orthoclase. It is to be observed that these angles were obtained from kinds having little soda as well as others having much. Moreover, loxoclase, in which the amount of soda is still larger, is monoclinic.

(*i*) *Loxoclase*. In grayish-white or yellowish crystals, a little pearly or greasy in lustre, often large, feebly shining, lengthened usually in the direction of the clinodiagonal. $O \wedge I=112^\circ\ 30'$, $O \wedge I'=112^\circ\ 50'$, $I \wedge I'=120^\circ\ 20'$, $O \wedge i\text{-}i$ (cleavage angle)$=90^\circ$, Breith. G.$=2{\cdot}6-2{\cdot}62$, Plattner. The analyses find much more soda than potash, the ratio being about 3 : 1, but how far this is due to mixture with albite has not been ascertained. From Hammond, St. Lawrence Co., N. Y. Named from λοξός, *transverse*, and κλάω, *I cleave*, under the idea that the crystals are peculiar in having cleavage parallel to the orthodiagonal section.

(*j*) Breithaupt has added still other names. His *Paradoxite*, from tin mines near Marienberg, etc., has (l. c.) $I \wedge I'=119^\circ\ 0'$; $I \wedge i\text{-}i=120^\circ\ 40'$, $I \wedge i\text{-}i=120^\circ\ 20'$; H.$=5\tfrac{1}{2}-6$; G.$=2{\cdot}440-2{\cdot}455$; color flesh-red. Contains potash as the alkali, with little or no soda. (*k*) His *Cottaite* is the grayish-white orthoclase in twins from granite in Carlsbad, Bohemia, circle of Elbogen; by his trials it has G.=2·6091—2·6098, H.=6—6½, and $I\wedge I$ about 120°; and by Rœssler's analysis (B. H. Ztg., xxv. 39) it contains 8 p. c. of soda to 5 of potash. But Redner and Bulk have found (anal. 14, 15) that it is an ordinary potash-feldspar with over 14 p. c. of potash, and has G.=2·55—2·573. (*l*) His *Muldan* is from Mulda near Freiberg; it is stated to have $I\wedge i\text{-}i=117°$, $I\wedge i\text{-}i=116°$, $O\wedge I=116°—116\frac{1}{2}°$, $O\wedge I=117°$; G.=2·54—2·56. Moll's analysis (No. 12) shows that it is common orthoclase, although irregular in its angles.

(*m*) *Lazurfeldspar* (Lasurfeldspath), a feldspar having H.=6, and G.=2·597, and the cleavage of orthoclase, found near Lake Baikal with lapis lazuli.

(*n*) *Perthite.* A flesh-red aventurine feldspar, consisting of interlaminated albite and orthoclase, as shown beyond. From Perth, Canada East.

(*o*) *Murchisonite* is similar flesh-red feldspar to perthite, with gold-yellow reflections in one direction, like sunstone; and stated to have also an unusual cleavage direction besides the two observed. From Dawlish and Exeter, England. Named after its discoverer, Murchison the geologist.

Weissigite, of Jenzsch, is in small whitish or reddish-white twin crystals, and is from the cavities of amygdaloid at Weissig near Dresden; G.=2·538—2·546. I. Lea has named (Proc. Ac. Philad., May, 1866) a greenish orthoclase from Lenni, Delaware Co., Pa., "almost without cleavage," *lennilite*; other specimens of the same locality, pearly and distinctly cleavable, *delawarite*; and a dull bluish-green subtransparent kind, of an aventurine character, containing minute particles bright and hexagonal (hematite?) from Blue Hill, 2 m. N. of Media, Pa., *cassinite*. These are announced only as varieties of orthoclase; but their distinctive characters are not such as to entitle them to special names. There is no place in the *science* of Mineralogy for names so given.

2. Compact Orthoclase or Orthoclase-felsite. This crypto-crystalline variety is common and occurs of various colors, from white and brown to deep red.

There are two kinds (*a*) the *jasper-like*, with a subvitreous lustre; and (*b*) the *ceratoid* or *wax-like*, with a waxy lustre. Some red kinds look closely like red jasper, but are easily distinguished by the fusibility. The orthoclase differs from the albite felsite in containing much more potash than soda. *Leelite*, named after J. F. Lee, is a deep, flesh-red variety, of waxy lustre, from Gryphyttan, Sweden.

The Swedish name *Hälleflinta* means *false flint.*

A. *Proportion of soda much less than that of potash; from* $\frac{1}{20}$ and less to $\frac{2}{3}$.

In anal. 5, G.=2·5685, colorless, trl.; 6, G.=2·555; 10, G.=2·44?, gangue of tinstone; 13, G.=2·548; 16, G.=2·56, in dioryte; 23, G.=2·575; 24, in amygdaloid, altered laumontite; 26–30, from the Erzgebirge; 33, G.=2·592, O. ratio 1 : 2·9 : 11·9, in granite with oligoclase and quartz, Harz; 34, G.=2·58, O. ratio 1 : 3·4 : 12·4, Harz; 35, G.=2·573, O. ratio 1 : 2·8 : 11·7, Harz; 36, G.=2·60; 39, G.=2·547; 45. G.=2·585; 46, G.=2·603, 3 m. from Wilmington; 49, G.=2·58; 50, G.=2·58; 54, G.=2·584–2·598, from Greenland, green; 55, G.=2·587–2·590, Breith.; 58, G.=2·57–2·58; 59, G.=2·595, O. ratio 1 : 3·4 : 12·5, Harz, in granite-like gangue from the Gabbro, with oligoclase; 60, in phonolite, Bohemia; 61, lava between Lecco and Forio; 63, 64, G.=2·576, from volcanic sand of Rockeskill; 66, 67, trachyte conglomerate of Langenberg in the Siebengebirge; 68, trachyte conglomerate of "Kleinen Rosenau" in the Siebengebirge; 69, from doleryte in the Siebengebirge, G.=2·567; 70, from porphyritic trachyte; 71, from granitoid trachyte; 73, compact white trachyte; 77, in a fine-grained granite.

Phillips, in an imperfect analysis of *murchisonite* (Phil. Mag. & Ann., i. 448), obtained S̈i 68·6, A̶l 16·6, K̇ 14·8. The mineral came from Dawlish, and is evidently orthoclase.

The *perthite* afforded Gerhard (ZS. G., xiv. 151) the same composition as obtained by Hunt, viz.: S̈i 65·83, A̶l 18·45, F̶e 1·72, Ċa *tr.*, Ṅa 5·06, K̇ 8·54, ign. 0·32=99·92. But he found, further, that it was divisible into thin reddish and whitish layers, which were respectively orthoclase and albite. These layers afforded him (l. c.):

	S̈i	A̶l	F̶e	Ċa	Ṅa	K̇
1. Red layers, *Orthoclase*	65·36	18·27	1·90	*tr.*	2·25	12·16=99·94
2. White layers, *Albite*	67·23	18·52	1·47	*tr.*	8·50	3·34=99·06

Thus proving that the supposed soda-orthoclase is really an intercrystallization of two homœomorphous species; and suggesting that other similar anomalies among the feldspars may have an analogous origin. The O. ratio in No. 1 is 0·94 : 3 : 12·49; in No. 2, 0·96 : 3 : 12·09.

An orthoclase, monoclinic in crystals and cleavage, fr. the nephelin-doleryte of Vogelsgebirge, afforded A. Knop (Jahrb. Min. 1865, 687) S̈i 59·69, A̶l 21·04, F̶e 2·27, Ṁn *tr.*, Ṁg *tr.*, Ċa 0·95, Ṅa 6·55, K̇ 8·61, Ḃa 2·27, Ṡr 0·36, T̈i *tr.*=101·74. The mineral is remarkable for the small amount of silica, large of alumina, and the presence of baryta. The peculiar constitution may be a result of partial alteration, or of crystallinic mixture; which is true is not ascertained. It is intermediate between orthoclase and hyalophane.

The following are analyses of different felsites, additional to those under ALBITE on page 351

Other analyses of felsites: C. W. C. Fuchs, Jahrb. Min., 1862, 803.

Pyr., etc.—B.B. fuses at 5; varieties containing much soda are more fusible. Loxoclase fuses at 4. Not acted upon by acids.

Obs.—Orthoclase is an essential constituent of many rocks.

1. *Granular crystalline.* *Granite* and *gneiss*, which consist of orthoclase, quartz, and mica. *Mica schist*, the same with less orthoclase and more mica. *Syenite* and *syenitic gneiss*, like the preceding, but containing hornblende in place of mica. *Granulyte*, a mixture of granular orthoclase and more or less quartz. *Albitic granite*, a granite containing albite as well as orthoclase. A similar rock contains oligoclase in place of albite. *Pyroxenyte*, a rock consisting of orthoclase and pyroxene. *Miascyte*, a granular slaty rock consisting of orthoclase and elæolite, from Miask in the Ural. These rocks contain the orthoclase in cleavable grains, and sometimes also in distinct disseminated crystals; when the latter is the case the rock is said to be *porphyritic*. The finest and largest crystals of orthoclase occur in granitic or feldspathic veins.

2. *Compact cryptocrystalline.* Orthoclase-*felsite*, or *leelite*, already described. It sometimes contains quartz in disseminated grains; and Dürocher has observed cases in which a felsite graduated into a granite or granulyte. As the rock was originally a clayey rock (derived from the wear (not the decomposition) of the minerals of granitic rocks) it is natural that there should be the transition here mentioned. The feldspar in some of the analyses below may be partly of oligoclase or albite. The *hälleflinta* of Sweden is for the most part here included.

As the granular orthoclase rocks, granite, gneiss, and the like, graduate into others containing hornblende, such as syenite, syenitic gneiss, etc., so the compact orthoclase-felsites may graduate into others that are hornblendic, though not visibly so;—and these last will indicate their hornblendic composition, not merely by their composition as ascertained by chemical analysis, but also by their high specific gravity. The spherules of *variolyte* of a white, grayish, or greenish-white color, are mostly a compact feldspar or felsite of some kind.

Porphyry, in part, consisting of a felsite base with disseminated opaque crystals of orthoclase; but this felsite base is seldom pure orthoclase. In the green antique porphyry, it is an intimate mixture of orthoclase and hornblende. [The feldspar is oligoclase or albite in some porphyry.]

Phonolyte (or clinkstone), a compact grayish rock, often containing crystals of glassy feldspar, and having a zeolite in the base along with orthoclase. [In some phonolite the feldspar is oligoclase.]

Trachyte, a grayish igneous rock of rough fracture, intermediate between phonolite and a granular crystalline rock, it owing its roughness of surface largely to the grains of glassy feldspar which mainly constitute it.

Argillyte and *talcose schist* generally contain more or less of orthoclase in a cryptocrystalline or undistinguishable state. Often, however, as analyses show, the alkalies are mostly wanting; and when so, the amount of feldspar is small; and it may be wholly absent.

3. *Amorphous.* *Obsidian* or volcanic glass is sometimes an impure orthoclase in a glassy state; and in other cases it is a mixture of orthoclase or labradorite and augite with chrysolite and much iron, the materials varying with the lavas of a volcano; for any lava will become glassy, and thus make obsidian, by rapid cooling. G.=2·25—2·8.

Pitchstone has the lustre of pitch rather than glass; *pearlstone* has a pearly lustre, and is sometimes in spherules (*spherulite*), or consists of spheroidal concretions. G.=2·3—2·4. The spherules of pyromeride, porphyry, etc., are quite similar, though usually having an excess of silica from mixed quartz. Pitchstone and pearlstone are sometimes in composition albite or oligoclase rocks rather than orthoclase, that is, contain soda, or soda and lime, instead of potash. See analyses below. Fuchs has suggested that these rocks derive their glassy portion from solidified water-glass and not from the fusion of a feldspar.

Krablite Forchhammer, or Baulite, appears to be a siliceous feldspathic mineral related to these concretions. It forms the basis of the trachyte, obsidian, and pitchstone of Iceland. According to von Walterhausen, it occurs also in triclinic crystals; and he deduces the oxygen ratio 1 : 3 : 24=$(\dot{R}+\bar{A}l)\,\ddot{S}i^{12}$. B.B. fuses only in thin splinters; in acids insoluble. H.=6. G.=2·656, Forch., 2·572, Walt.*

---

Many localities have been enumerated above. Fine crystals are found at Carlsbad and Elbogen in Bohemia (twins, f. 314, 315); Katherinenburg in Siberia; Arendal in Norway; Baveno in Piedmont; Lomnitz in Silesia; Land's End and St. Agnes in Cornwall; Albaschka near Mursinsk and near Schaitansk in the Urals; the Mourne mountains, Ireland, with beryl and topaz; at Rubieslaw in Aberdeenshire, Scotland, etc.; in great abundance in the trachyte of the Drachenfels on the Rhine; also in the lavas which devastated the island of Ischia, near Naples, in 1802; at Vesuvius, where it may be obtained in profusion in the valley called Fossa Grande.

In the U. States, orthoclase in crystals occurs in *Maine*, on the island Mt. Desert, fine green; at the tourmaline locality, Paris. In *N. Hamp.*, at the Acworth beryl locality. In *Mass.*, at South Royalston and Barre, often large crystals; at Three Rivers, in Palmer. In *Conn.*, at the gneiss quarries of Haddam and the feldspar quarries of Middletown, crystals a foot long, and 6 or 8 in. thick; near Bradleysville, in the western part of Litchfield, crystals 2–3 in. long, abundant. In *N. York*, in St. Lawrence Co., at Rossie, 2 m. N. of Oxbow; the crystals are white or bluish-white, and sometimes an inch across; also 8 m. from Potsdam, on the road to Pierremont, where crystals a foot through are said to have been found; and near DeLong's mills in the town of Hammond, with apatite and zircon, where the *loxoclase* is obtained; in Lewis Co., orthoclase occurs both crystallized and massive in white limestone near Natural Bridge, with scapolite and sphene; in Orange Co., crystals near West Point; more abundant and interesting forms are found at Rocky Hill, in Warwick, with tourmaline and zircon; and at Amity and Edenville; in Saratoga Co., at the Greenfield chrysoberyl locality, white translucent crystals, usually coated with silvery mica. In *Penn.*, in crystals at Leiperville, Mineral Hill, Delaware Co., and W. Bradford, at Poor House quarry, Chester Co. (chesterlite); sunstone in Kennett Township. In *N. Car.*, at Washington Mine, Davidson Co., in white and yellowish crystals (anal. 41).

Massive orthoclase is abundant at the above-mentioned localities, besides many others. Green at Mt. Desert, Me., near S. W. Harbor; at Rockport, Mass. An aventurine variety, with bright coppery reflections in spots, at Leiperville, Pennsylvania. Adularia, at the Falls of the Yantic, near Norwich, Conn., at Brimfield, Mass., with iolite, and at Parsonfield, Me.; and sunstone at Lyme, Conn. (Some of these may be oligoclase.) Kaolin, at Andover, Mass., and abundantly in New Milford, Kent, and Cornwall, Conn., and in the counties of Essex and Warren, New York; also in New Garden, Chester Co., Pa., abundant. Necronite, at Roger's Rock, Essex Co., and at Thomson's quarry, near 196th street, New York.

For recent observations on cryst., see Descl. Min., i.; Hessenberg's Min. Notizen, Nos. I., II., IV., V.; Websky, ZS. G., xv. 677; Kokscharof, Min. Russl., v. 115; F. Scharff., Abh. d. Senck. Ges., vi.

Alt.—Feldspar may be altered through infiltrating waters carrying more or less carbonic acid in solution (Forchhammer, Fournet, Bischof); also through the action of waters rendered acid by the decomposition of sulphids (Mitscherlich); also by ordinary waters holding traces of alkaline and other ingredients in solution (Bischof).

The presence of a sulphid of iron, or a mineral containing protoxyd of iron, as some mica, garnet, etc., is often the first occasion of the change. The decomposition of the mineral with the attendant oxydation of the iron distributes ferruginous waters through the rock (or sulphate of iron from the altered sulphid), and thus, by a disaggregating or decomposing action, prepares the way for other agencies.

Other analyses of obsidian, Deville (Bull. G. Soc. Fr., II. viii. 427); of pumice, ib.; also Sonnäffle (J. pr. Ch., liv. 16).

When the infiltrating waters contain trace[illegible]f carbonic acid, the feldspar acted on first loses its lime, if a lime feldspar, by a com[illegible]ation of t[illegible] lime with this acid; next, its alkalies are carried off as carbonates if the supply [illegible]bonic a[illegible]d continues, or otherwise as silicates in solution. The change thus going on ends[illegible]ng, *kaolin* or some other hydrous silicate. The carbonate of soda or potash, or the silicate of th[illegible] bases, set free, may go to the formation of other minerals —the production of pseudomorphic or metamorphic changes—and the supplying fresh and marine waters with their saline ingredients.

Kaolin is generally a simple hydrous silicate of alumina (see **Kaolinite**), expressed by the formula $\bar{\bar{A}}l\,\ddot{S}i^{2}+2\dot{H}$=Silica 46·3, alumina 39·8, water 13·9. Orthoclase in changing to it loses $1\dot{K}+\frac{4}{3}\ddot{S}i$. Part of the silica set free may go off with more or less of the potash, or may form opal, quartz, siliceous sinter. The alumina also is often in part removed. The same explanation is readily applied to the change in albite or other feldspars.

When the change is not carried on to the exclusion of the protoxyd bases, certain zeolites may result, especially, as Bischof states, when labradorite is the feldspar undergoing alteration, which species he describes as giving origin to the species mesolite. Massive nepheline or elæolite is a still more common source of zeolites. Anal. 52, by Scheerer, is of orthoclase enveloping the zeolite bergmannite, and 53, of the same enclosed in bergmannite, this zeolite having apparently been formed out of other portions of the orthoclase.

When the waters contain traces of a magnesian salt—a bicarbonate or silicate—the magnesia may replace the lime or soda, and so lead to a steatitic change, or to a talc when the alumina is excluded; and when augite or hornblende is present, it may give origin to chlorite.

The action of sulphurous acid from volcanic fumaroles produces often a complete destruction of the feldspar and other minerals present, giving rise to deposits or incrustations of silica, in some of its various forms, and also halloysite, kaolin, etc.

Steatite, talc, chlorite, kaolin, lithomarge, mica, laumontite, occur as pseudomorphs after orthoclase or albite; and tin ore and calcite often replace these feldspars by some process of solution and substitution. Labradorite more rarely forms kaolin.

Orthoclase is also described as occurring altered to albite. This has been mentioned as an example of *paramorphism*, the two species being dimorphous. But as these feldspars occur together in the same rock, and must have been formed under very similar circumstances, we can hardly suppose that either is liable to a change like that of a dimorphous compound to the form of the other.

Artif.—Artificial feldspar has been observed in crystals in furnace scoria at Mansfeld, Sangerhausen, near Laimbach, and near Stolberg. Analyses: 1, 2, Heine; 3, Abich; 4, Rammelsberg:

	$\ddot{S}i$	$\bar{\bar{A}}l$	$\bar{\bar{F}}e$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	
1. Sangerhausen	64·53	19·20	1·20	—	1·33	—	—,	$\dot{C}u$ 0·27 Heine.
2. "	65·95	18·50	0·68	—	4·28	10·47	—,	$\dot{C}u$ 0·13 Heine
3. "	65·03	16·84	0·88	0·34	0·34	0·65	15·26,	$\dot{C}u$ 0·30 Abich.
4. Laimbach	63·96	—	20·04	0·54	0·43	0·65	15·26=98·21	Ramm.

The oxygen ratio afforded is 1 : 3 : 12. But the last is an *iron-orthoclase*, the alumina being replaced by sesquioxyd of iron.

Ersbyite. (Wasserfreier Scolezit [fr. Pargas] *N. Nordensk.*, Schw. J., xxxi. 417, 1821. Anhydrous Scolecite. Scolexerose *Beud.*, Tr., ii. 55, 1832. Var. of Labrador *Frankenheim*, Syst. d. Kryst., 136, 1842. Ersbyit *A. E. Nordensk.*, Finl. Min., 129, 1853. Kalk-Labrador *Ramm.*, Min. Ch., 595, 1860.) Monoclinic, with the angles nearly of orthoclase; *I* ∧ *I*=118° 44′, *O* ∧ *i-i*=115° 12′ and 64° 48′, *I* ∧ *i-3*=149° 55′, *i-i* ∧ *i-3*=150° 16′, *I* ∧ 2-*i*=134° 49′, *O* ∧ 2-*i*=99° 48′ (angles by Nord., with the common goniometer). Observed planes: *O*; vertical, *I*, *i-i*, *i-3*; clinodome, 1-*i*; hemidome, 2-*i*. Cleavage: *O* perfect; *i-i* less perfect. H.=6; lustre vitreous, pearly on surface of cleavage; color white or grayish-white. N. Nordenskiöld obtained in an analysis (l. c.) $\ddot{S}i$ 54·13, $\bar{\bar{A}}l$ 29·23, $\dot{C}a$ 15·46, $\dot{H}$ 1·07=99·87, which affords the O. ratio 1 : 3 : 6, or that of labradorite, to which species it has been referred by Frankenheim and Rammelsberg. A labradorite without alkali and with the angles of orthoclase is so much of an anomaly as to be at least of very improbable existence. It may well be *altered orthoclase* and thereby pseudomorphous. Nordenskiöld, while making the form *monoclinic* in the text, states that he obtained the angle 90° 22′ between the two cleavages with a reflective goniometer, and suggests that the form may possibly be triclinic. Still the other angles are so closely those of orthoclase that this view appears quite improbable, as he also must regard it, since he does not adopt it in the text. It was called *anhydrous scolecite* by N. Nordenskiöld, because the O. ratio was that of scolecite *minus* the water.

III. SUBSILICATES.

ARRANGEMENT OF THE SPECIES.

A. Oxygen ratio of bases and silica 4 : 3.

I. CHONDRODITE GROUP.

819. CHONDRODITE	$\dot{Mg}^8\ddot{Si}^3$	$Mg_8\Theta_2\|(\Theta,F)_{12}\|Si_3$

825. TOPAZ	$\ddot{\bar{A}}l\,\ddot{Si}$, with F repl. one-fifth the O	$\beta\bar{A}l_2F\|\Theta_4\|Si$

III. EUCLASE GROUP Monoclinic. Containing other bases besides sesquioxyds.

826. EUCLASE	$(\frac{1}{6}\dot{H}^3+\frac{2}{6}\dot{B}e^3+\frac{3}{6}\ddot{\bar{A}}l)\ddot{Si}$	$(\frac{1}{6}H_2+\frac{2}{6}\bar{B}e+\frac{3}{6}\beta\bar{A}l)_2\Theta\|\Theta_4\|Si$
827. DATOLITE	$(\frac{1}{6}\dot{H}^3+\frac{2}{6}\dot{C}a^3+\frac{3}{6}\ddot{B})\ddot{Si}$	$(\frac{1}{6}H_2+\frac{2}{6}\bar{C}a+\frac{3}{6}\beta B)_2\Theta\|\Theta_4\|Si$

2. *Containing titanic acid.*

I. GUARINITE GROUP. Tetragonal.

828. GUARINITE	$(\dot{C}a+\ddot{Ti})\ddot{Si}$, or $(\frac{1}{3}\dot{C}a^3+\frac{2}{3}\ddot{Ti}^{\frac{3}{2}})\ddot{Si}$	$(\frac{1}{3}\bar{C}a+\frac{2}{3}\gamma\bar{T}i)_2\Theta\|\Theta_4\|Si$

II. TITANITE GROUP. Anisometric.

829. TITANITE	$(\frac{1}{3}\dot{C}a^3+\frac{2}{3}\ddot{Ti}^{\frac{3}{2}})\ddot{Si}$	$(\frac{1}{3}\bar{C}a+\frac{2}{3}\gamma\bar{T}i)_2\Theta\|\Theta_4\|Si$
830. GROTHITE	$(\dot{R}^3, \bar{R}, \ddot{Ti}^{\frac{3}{2}})\ddot{Si}$	$(\frac{3}{8}\bar{C}a+\frac{1}{8}\beta\bar{F}e+\frac{1}{2}\gamma\bar{T}i)_2\Theta\|\Theta_4\|Si$
831. KEILHAUITE	$(\dot{R}^3, \bar{R}, \ddot{Ti}^{\frac{3}{2}})\ddot{Si}$	$(\frac{4}{15}\bar{R}+\frac{4}{15}\beta\bar{R}+\frac{7}{15}\gamma\bar{T}i)_2\Theta\|\Theta_4\|Si$
832. TSCHEFFKINITE	$(\dot{R}^3, \ddot{Ti}^{\frac{3}{2}})\ddot{Si}$	$(\frac{1}{3}\bar{R}+\frac{2}{3}\gamma\bar{T}i)_2\Theta\|\Theta_4\|Si$

C. Oxygen ratio of bases and silica 2 : 1.

I. STAUROLITE GROUP. Containing no titanic acid.

333. STAUROLITE $(\dot{\mathrm{H}}^3, \dot{\mathrm{R}}^3, \ddot{\mathrm{R}})^4\ddot{\mathrm{S}}\mathrm{i}^3$ $(\frac{1}{3}(\mathrm{H}_2, \mathrm{R})+\frac{2}{3}\beta\mathrm{R})_4\Theta_2\|\Theta_4\|\mathrm{Si}$

II. SCHORLOMITE GROUP. Containing titanic acid as a base.

334. SCHORLOMITE $(\dot{\mathrm{R}}^3, \ddot{\mathrm{R}}, \ddot{\mathrm{T}}\mathrm{i}^{\frac{3}{2}})^4\ddot{\mathrm{S}}\mathrm{i}^3$ $(\frac{1}{3}\mathrm{R}+\frac{1}{3}\beta\mathrm{R}+\frac{1}{3}\gamma\mathrm{R})_4\Theta_2\|\Theta_4\|\mathrm{Si}$

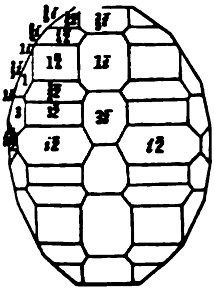
Appendix.—335. SAPPHIRINE, $\ddot{\mathrm{S}}\mathrm{i}$, $\ddot{\mathrm{A}}\mathrm{l}$, $\dot{\mathrm{M}}\mathrm{g}$.

In the Andalusite group, the species andalusite and topaz are approximately isomorphous; for if *i*-$\breve{2}$ ∧ *i*-$\breve{2}$ in the latter is made the fundamental prism, then $I \wedge I = 93° 11'$, while it is 90° 44′ in andalusite. Euclase, datolite, and the species of the Titanite group are also isomorphous; the angle of *I* being severally, 115°, 115° 8′, and 118° 31′; and *O* on a clinodome=161° 51′, 162° 27′, 159° 39′.

319. CHONDRODITE. Chondrodit [= Silicate of Magnesia and Iron] *d'Ohsson*, Ak. H. Stockh., 206, 1817. Condrodite *H.* Maclureite, Fluosilicate of Magnesia (fr. Sparta, N. J.), *Seybert*, Am. J. Sci., v. 336, 1822. Brucite (fr. N. J. and N. Y.) *Gibbs*, Cleaveland's Min., 295, 1822, Nuttall in Am. J. Sci., v. 245, 1822. Humite *Bourn.*, Cat., 52, 1817.

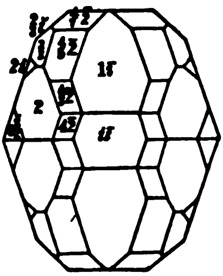
Orthorhombic. Often hemihedral in octahedral planes, producing forms monoclinic in character. $I \wedge I = 94° 26'$ and 83° 34′. Crystals of three types, as in the following figures.

323



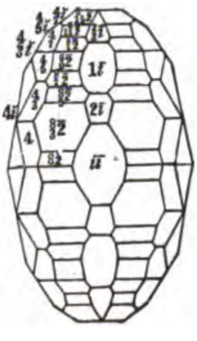
Humite: Type I.

324



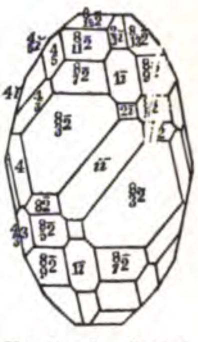
Humite: Type II.

325



Humite: Type III.

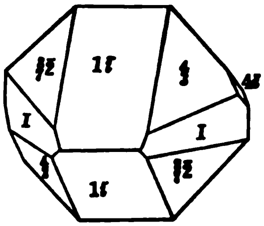
326



Humite: hemihedral.

Type I., $a : b : c = 1{\cdot}4678 : 1 : 1{\cdot}0805$; II., $1{\cdot}5727 : 1 : 1{\cdot}0805$; III., $1{\cdot}4154 : 1 : 1{\cdot}0805$. Observed planes in Vesuvian crystals as in figs. 323 to 326, with also $\frac{1}{3}$-ĭ in type II.; the two unlettered planes on figs. 325, 326, 4-$\frac{3}{2}$, 12-$\frac{3}{2}$; another plane in the same series (f. 325) 1-$\frac{3}{2}$. Observed planes in chondrodite as in fig. 327, with also *O*, *i*-ĭ, 2-ĭ, $\frac{2}{3}$-ĭ, $\frac{3}{4}$-$\frac{3}{2}$, $\frac{3}{4}$-$\frac{5}{2}$. Fig. 326 left-handed hemihedral, 327 right-handed hemihedral. Angles in the different types of humite:

327



Chondrodite.

I. $O \wedge 1\text{-}\bar{\imath}=124^\circ\ 16'$
$O \wedge 1=116\ 34$
$O \wedge 3\text{-}\bar{\imath}=102^\circ\ 48'$
$O \wedge 3\text{-}\breve{\imath}=103\ 47$
$O \wedge 1\text{-}\breve{2}=121\ 44$
$1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}$, bas., $111\ 28$
$O \wedge \frac{2}{3}\text{-}\breve{2}=112\ 24$
$i\text{-}\breve{\frac{2}{3}} \wedge i\text{-}\breve{\frac{2}{3}}$, front, $=71\ 32$

II. $O \wedge 1\text{-}\bar{\imath}=122\ 27$
$O \wedge 2=103\ 8$
$O \wedge \frac{2}{3}\text{-}\breve{\imath}=135\ 52\frac{1}{2}$
$O \wedge 4\text{-}\breve{2}=98\ 13$
$O \wedge 2\text{-}\breve{\imath}=108\ 58$
$1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}$, ov. $i\text{-}\bar{\imath}$, $=115\ 6$

III. $O \wedge 1\text{-}\bar{\imath}=125^\circ\ 14\frac{1}{2}'$
$O \wedge 2\text{-}\bar{\imath}=109\ 27$
$O \wedge 4=97\ 23$
$O \wedge \frac{4}{3}\text{-}\breve{\imath}=119\ 47$
$O \wedge 4\text{-}\breve{\imath}=100\ 48$
$O \wedge \frac{8}{15}\text{-}\breve{2}=140\ 15$
$O \wedge \frac{8}{7}\text{-}\breve{2}=119\ 17$
$O \wedge 8\text{-}\breve{2}=94\ 35$
$O \wedge \frac{4}{3}=111\ 15$
$1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}=109\ 31$
$1\text{-}\bar{\imath} \wedge \frac{4}{3}=134\ 23$
$\frac{4}{3} \wedge \frac{8}{7}\text{-}\breve{2}$, ov. I, $=126\ 52$

Observed angles with the common goniometer in chondrodite of N. Jersey (Dana): $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}=112^\circ$ (for mean of humite types $112^\circ\ 2'$); $1\text{-}\bar{\imath} \wedge \frac{4}{3}=136^\circ$; $1\text{-}\bar{\imath} \wedge \frac{8}{7}\text{-}\breve{2}=157^\circ$, $\frac{4}{3} \wedge \frac{8}{7}\text{-}\breve{2}$, ov. I, $=127^\circ$, $I \wedge I$, adj., $=85^\circ$, $4\text{-}\bar{\imath}$ on edge above it 168°; of Pargas (Nordenskiöld) $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}=114^\circ\ 37'$ (in type II. above $115^\circ\ 6'$), $O \wedge \frac{2}{3}\text{-}\breve{\imath}=136^\circ\ 1'$, $O \wedge 2\text{-}\breve{\imath}=109^\circ\ 3'$.

Twins: composition-face $\frac{4}{7}\text{-}\breve{\imath}$ in type I.; $\frac{2}{3}\text{-}\breve{\imath}$ and $\frac{2}{5}\text{-}\breve{\imath}$ in II.; $\frac{4}{3}\text{-}\breve{\imath}$ in III.; the last sometimes producing stellate forms of six crystals, each hemihedral. Cleavage indistinct. Usually in imbedded grains or masses of a somewhat granular texture.

H.=6—6·5. G.=3·118—3·24. Lustre vitreous—resinous. Color white, yellow, pale yellow or brown; sometimes red, apple-green, black, gray. Streak white, or slightly yellowish, or grayish. Transparent—subtranslucent. Fracture subconchoidal—uneven.

Var.—1. Ordinary *chondrodite*. In imbedded crystals, masses, or grains, subtranslucent or opaque, more or less resinous in lustre, and surfaces hardly polished; the crystals sometimes 2 inches or more broad. Colors the above, excepting white. G.=3·118, from N. Jersey, Thomson; 3·24, fr. Eden, N. Y., id.; 3·199, fr. Finland, Haidinger.

2. *Humite*. In small implanted, transparent to translucent, polished glassy crystals, from Vesuvius; (*a*) type I.; (*b*) type II.; (*c*) type III., the most common. Colorless to citron-yellow, honey-yellow, and brownish. G.=3·234, white, type I.; 3·177, yellow, type II.; 3·199, brown, type III.; 3·186, yellowish, type III.; Scacchi.

Comp.—$\dot{\text{M}}\text{g}^{8}\ \ddot{\text{Si}}^{3}$, with part of the oxygen replaced by fluorine; $\frac{1}{12}$ in chondrodite; $\frac{1}{24}$ in humite, type I., $\frac{1}{18}$ in type II., $\frac{1}{36}$ in type III., Ramm.

Analyses: 1, Dr. W. Langstaff (Am. J. Sci., vi. 172, analysis made in 1811); 2, Seybert (Am. J Sci., v. 336); 3, Rammelsberg (Pogg., liii. 130, and 1st Suppl., 38); 4, W. Fisher (Am. J. Sci. II. ix. 85); 5, Thomson (Ann. Lyc. N. York, iii 54); 6–10, Rammelsberg (Pogg., liii. 130, lxxxvi 413):

Pyr., etc.—B.B. infusible; some varieties blacken and then burn white. Fused with salt of phosphorus in the open tube gives a reaction for fluorine. With the fluxes a reaction for iron. Gelatinizes with acids. Heated with sulphuric acid gives off fluorid of silicon.

Obs.—Chondrodite occurs mostly in granular limestone. It is found near Abö, in the parish of Pargas in Finland, and at Aker and Gulsjö in Sweden; at Taberg in Wermland; at Boden in Saxony; on Loch Ness in Scotland; at Achmatovsk in the Ural, along with perofskite; and in the mines of Schischimsk with red apatite. Humite occurs at Somma, in ejected masses of a kind of granitic rock, along with forsterite, biotite, pyroxene, magnetite, etc.

Abundant in the counties of Sussex, N. J., and Orange, N. Y., where it is associated with spinel, and occasionally with pyroxene and corundum. In *N. Jersey*, at Bryam, orange and straw-colored chondrodite, and also a variety nearly black, occurs with spinel; at Sparta, a fine locality of honey-yellow chondrodite; a mile to the north of Sparta the best locality of this mineral in N. J.; at Vernon, Lockwood, and Franklin. In *N. York*, in Orange Co., in Warwick, Monroe, Cornwall, near Greenwood Furnace, and at Two Ponds, and elsewhere; near Edenville in fine specimens on the land of Mr. Houston; also sparingly in Rossie, on the bank of Laidlaw Lake. In *Mass.*, at Chelmsford, with scapolite. In *Penn.*, near Chaddsford, in Harvy's quarry, of yellow and orange colors, abundant. In *Canada*, in limestone at St. Crosby, St. Jerome, St. Adele, Grenville, etc., abundant.

The name chondrodite is from χόνδρος, *a grain*, alluding to the granular structure. *Brucite* was given by Col. Gibbs after Dr. Bruce, editor of the American Mineralogical Journal; *Maclureite* by Seybert, after Wm. Maclure. The mineral was first discovered in New Jersey by Dr. Bruce. Fluorine was first detected in it in 1811, by Dr. Langstaff of New York, whose analysis (No. 1) gives very nearly the correct constitution of the species. Cleaveland, in the first edition of his mineralogy (issued in 1816), at p. 185, in a brief mention of the undescribed species, speaks of it as a *fluate*, calling it *fluate of magnesia*, he evidently having had an imperfect report of Dr. Langstaff's examination, the results of which had not then been published. Dr. Torrey obtained similar results to those of Dr. Langstaff in 1818. See on these points Am. J. Sci., vi. 171, 1823. D'Ohsson analyzed the mineral in 1817 without finding the fluorine, he obtaining (l.c.) $\ddot{\mathrm{Si}}$ 38·00, $\dot{\mathrm{Mg}}$ 54·00, $\dot{\mathrm{Fe}}$ 5·10, $\ddot{\bar{\mathrm{Al}}}$ 1·50, $\dot{\mathrm{K}}$ 0·86 $\ddot{\bar{\mathrm{Mn}}}$ *tr.*, a result very wide from the true composition. Humite was shown to be identical with chondrodite in composition by Rammelsberg.

On cryst. see Scacchi, Pogg., 1851, Ergänz., iii. 161, who identified and described the three types of humite; also Hessenberg, Min. Not., ii. 15; Nordenskiöld on chondrodite of Pargas, Pogg. xcvi. 118. The author adopts a modified view of Scacchi's types, first brought out in Am. J. Sci. II. xiv. 175.

Alt.—Chondrodite altered to serpentine has been observed at Sparta, N. J., with spinel and mica.

420. TOURMALINE. *Early syn. of precious T.* Turamali, Turmalin (fr. Ceylon), *Ceylon name*, *Garmann*, Curiosæ Speculationes, etc., von einem Liebhaber, der Immer Gern Speculirt, Chemnitz, 1707. Rhombohedral. $R \wedge R=103°$, $O \wedge R=134° 3'$; $a=0·89526$. Observed planes: rhombohedrons, $\frac{1}{4}$, 1 (R), $\frac{4}{3}$, $\frac{7}{4}$, $\frac{5}{2}$, 5, $\frac{11}{3}$?, -2, $-\frac{5}{4}$, $-\frac{7}{8}$, $-\frac{1}{2}$, $-\frac{1}{5}$; scalehedrons, $\frac{1}{2}^{2}$, $\frac{1}{2}^{3}$, $\frac{1}{2}^{5}$, $1^{\frac{4}{3}}$, 1^{3}, $\frac{1}{4}^{3}$, $\frac{2}{5}^{2}$ (the last replacing angle between $-\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{4}^{3}$); prisms, I, i-2, i-$\frac{7}{5}$, i-$\frac{5}{4}$. Usually hemihedral, being often unlike at the opposite extremities, or hemimorphic, and the prisms often triangular. Cleavage: R, $-\frac{1}{2}$, and i-2, difficult. Sometimes massive compact; also columnar, coarse or fine, parallel or divergent.

H.=7—7·5. G.=2·94—3·3. Lustre vitreous. Color black, brownish-black, bluish-black, most common; blue, green, red, and sometimes of rich shades; rarely white or colorless; some specimens red internally and green externally; and others red at one extremity, and green, blue, or black at the other. Dichroic; some, yellowish-brown axially, asparagus-green transversely; dark brownish-violet axially, greenish-blue transversely; purple axially, bluish transversely; etc. Streak uncolored. Transparent—opaque; greater transparency across the prism than in the line of the axis. Fracture subconchoidal—uneven. Brittle. Pyroelectric.

Var.—1. *Ordinary.* In crystals. (*a*) *Rubellite;* the red sometimes transparent; the Siberian is mostly violet-red, the Brazilian rose-red; that of Chesterfield and Goshen, Mass., pale rose-red and opaque; that of Paris, Me., fine ruby-red and transparent. (*b*) *Indicolite;* the blue, either pale or bluish-black; named from the indigo-blue color. (*c*) *Brazilian Sapphire* (in jewelry); Berlin-blue and transparent; (*d*) *Brazilian Emerald, Chrysolite* (or *Peridot*) *of Brazil;* green and transparent. (*e*) *Peridot of Ceylon;* honey-yellow. (*f*) *Achroite;* colorless tourmaline, from Elba. (*g*) *Aphrizite;* black tourmaline, from Krageröe, Norway. (*h*) *Columnar* and *black;* coarse columnar. Resembles somewhat hornblende, but has a more resinous fracture, and is without distinct cleavage or anything like a fibrous appearance in the texture.

Kupffer found the angle $\frac{1}{2}\wedge\frac{1}{2}$ in the green tourmaline of St. Gothard 133° 8′; in the black of Siberia, 133° 13′; in the red of Siberia, 133° 2′; giving 134° 6′, 134° 3′, and 133° 56′ for $O\wedge\frac{1}{2}$. Brooke found for the angle $O\wedge\frac{1}{2}$ in a white crystal, 134° 7′; green, 134° 2′ 24″; clear brown, 133° 56′; red, 133° 48′; black, 133° 47′ 12″.

The varieties in composition and the subdivisions suggested thereby are given below.

Comp.—O. ratio for bases (the boric acid here included) and silica 4 : 3 (Ramm.); whence $(\dot{R}^3, \bar{R}, \ddot{B})^6\ddot{Si}^9$. The O. ratio for the protoxyds, sesquioxyds, and boric acid ($\dot{R}$, $\bar{R}$, $\ddot{B}$) varies greatly; group I. (see beyond) affording mostly 4 : 12 : 4; II., 4 : 15 : 5; III., 4 : 21 : 6, 4 : 24 : 7, etc.; IV., 4 : 40 : 12, 4 : 36 : 11, etc.; V., 4 : 48 : 13, 4 : 56 : 12, etc. The special formula for group I. would consequently be $(\dot{R}^3)^6\ddot{Si}^9+3\,\bar{R}^6\ddot{Si}^9+\ddot{B}^6\ddot{Si}^9$ or $(\frac{1}{4}\dot{R}^3+\frac{5}{8}\bar{R}+\frac{1}{8}\ddot{B})^6\ddot{Si}^9$; for analysis 23 in group V. $(\dot{R}^3)^6\ddot{Si}^9+14\,\bar{R}^6\ddot{Si}^9+3\ddot{B}^6\ddot{Si}^9$ or $(\frac{1}{18}\dot{R}^3+\frac{14}{18}\bar{R}+\frac{3}{18}\ddot{B})^6\ddot{Si}^9$, and these (excluding analysis 26) are the extreme variations.

A. Mitscherlich, by a new method of analysis (J. pr. Ch., lxxxvi. 1), obtained the iron as protoxyd in several trials, finding 16·06 and 16·30 in that of Bovey Tracey (No. 13, beyond); 5·69 and 5·66 in that of St. Gothard (No. 9); 17·14 and 17·29 in that of Sonnenberg (No. 15); 7·54, 7·65, and 7·57 in that of Sarapulsk near Mursinsk (No. 17); and 6·74 in that of Brazil (No. 21). But Scheerer takes the ground that Mitscherlich's method of analysis is less satisfactory than others, and the subject is still in doubt. Mitscherlich's determinations, introduced into Rammelsberg's analyses as done by himself, afforded, in the 14 cases which he investigated, the following for the oxygen of $\dot{R}+\bar{R}+\ddot{B}$, that of the $\ddot{Si}$ being 3 : I., *Iron-magnesia tourmaline*—3·90 (No. 7); 4·10 (No. 8); 4·09 (No. 9); 4·07 (fr Havredal); 4·15 (fr. Ramfosse); 4·11 (No. 10, Haddam); 4·12 (No. 11, Haddam); 4·21 (No. 12, Unity, Me.); II., *Iron tourmaline*—4·09 (No. 13); 4·32 (No. 14); 4·03 (No. 15); 4·23 (fr. Saar); 4·12 (fr. Langenbielau); 3·99 (No. 16). The results leave little question as to the normal ratio for the species being 4 : 3.

Analyses: 1–26, Rammelsberg (Pogg., lxxx 409, lxxxi. 1) arranged as follows:

I. *Magnesia tourmaline*, G.=3—3·07, mean 3·05.
II. *Iron-magnesia tourmaline*, G.=3·05—3·2, mean 3·11.
III. *Iron tourmaline*, G.=3·13—3·25.
IV. *Iron-manganese-lithia tourmaline*, G.=2·94—3·11, mean 3·083.
V. *Lithia tourmaline*, G.=3—3·1, mean 3·041.

Anal. 27–29, Gmelin (Schw. J., 299, xxxviii. 514, Pogg., ix. 172); 30, Ulex (J. pr. Ch., xcvi. 37); 31, C. W. C. Fuchs (Jahrb. Min. 1862, 800); 32, 34, 35, 37, 38, Gmelin (l. c.): 33, 36, 39, 40, Hermann (J. pr. Ch., xxxv. 232):

Pisani has examined a specimen of true taltalite (Am. J. Sci., II. xliii. 407), and shown that it is tourmaline with oxyd of copper and other impurities. Domeyko made it a silicate of copper (l. c., and Forbes, Phil. Mag., IV. xxv. 111). Ulex's specimen (anal. 30) was procured from a cargo of copper ores landed at Hamburg, and identified as taltalite by its characters.

Pyr., etc.—I., fuse rather easily to a white blebby glass or slag; II., fuse with a strong heat to a blebby slag or enamel, either white, greenish, or brownish; III., fuse with difficulty, or, in some, only on the edges, to a brownish, brownish-red, gray, or black slag; IV., fuse on the edges, and often with great difficulty, to a yellowish, grayish, bluish, or whitish slag or enamel, and some are infusible; V., infusible, but becoming white or paler, sometimes, as the Paris (Me.) rubellite, affording a fine enamel on the edges (Ramm.). With the fluxes many varieties give reactions for iron and manganese. Fused with a mixture of bisulphate of potash and fluor-spar gives a strong reaction for boric acid. By heat alone tourmaline loses weight from the evolution of fluorid of silicon and perhaps also fluorid of boron; and only after previous ignition is the mineral completely decomposed by fluohydric acid. Not decomposed by acids (Ramm.). After fusion perfectly decomposed by sulphuric acid (v. Kobell).

Obs.—Tourmaline is usually found in granite, gneiss, syenite, mica, chloritic or talcose schist, dolomite, granular limestone, and sometimes in sandstone near dykes of igneous rocks. The variety in granular limestone or dolomite is commonly brown.

Foreign localities are mentioned above. Small brilliant black crystals in decomposed feldspar, at Sonnenberg in the Harz, are called *aphrizite*. Rubellite and green tourmaline occur near Katherinenburg in Siberia; pink crystals are found at Elba. Pale yellowish-brown crystals in talc at Windisch Kappell in Carinthia; green at Airolo, Switzerland; white specimens (*achroite*) come from St. Gothard, Siberia, and Elba. A specimen, formerly in the Grand Duke's collection at Florence, measuring 11 inches square, contains 4 erect green tourmalines and 1 prostrate, 2, 4, and 2½ inches long, and ¾ to 1 inch thick.

In Great Britain, fine black crystals have been obtained near Bovey Tracey in Devon; also found in Cornwall at different localities; green near Dartmoor in Devon; black near Aberdeen in Scotland, and elsewhere; dark brown at Dalkey in Co. Dublin, Ireland; green near Dunfanaghy, Co. Donegal; green and red at Ox mountain, near Sligo.

In the U. States, in *Maine* at Paris and Hebron, magnificent red and green tourmalines with lepidolite, etc., some crystals over an inch in diameter, transparent, ruby-red within, surrounded by green, or red at one extremity and green at the other; also blue and pink varieties; at Albany, green and black; at Streaked Mtn., black. In *Mass.*, at Chesterfield, red, green, and blue, in a granite vein with albite, uranite, and microlite, the crystals small and curved, nearly opaque, and fragile, the green crystals often with distinct prisms of red color inside, especially when in smoky quartz; at Goshen, similar, the blue in greater perfection; at Norwich, New Braintree, and Carlisle, good black crystals. In *N. Hamp.*, Alstead, Grafton, Sullivan, Acworth, and Saddleback Mt.; at Orford, large brownish-black crystals abundant in steatite. In *Vermont*, at Brattleboro, black. In *Conn.*, at Monroe, perfect dark brown crystals in mica-slate near Lane's mine, sometimes two inches in length and breadth; at Haddam, interesting black crystals in mica slate with anthophyllite, also in granite with iolite, and also at the gneiss quarries, on the east side of the river. In *N. York*, near Gouverneur, light and dark brown crystals, often highly modified, with apatite and scapolite in granular limestone (f. 338, 339); at Canton; in simple prisms in the same rock near Port Henry, Essex Co.; at Schroon, with chondrodite and scapolite; at Crown Point, one mile south of village, fine brown crystals; at the chrysoberyl locality near Saratoga, N. Y., black; at Alexandria, Jefferson Co.; at Kingsbridge, brown, yellowish or reddish-brown crystals in dolomite; near Edenville, gray or bluish-gray and green in three-sided prisms occur; short black crystals in the same vicinity, and at Rocky Hill, sometimes 5 inches in diameter; a mile southwest of Amity, yellow and cinnamon-colored crystals with spinel in calcite; also near the same village a clove-brown variety with hornblende and rutile in granular limestone. In *N. Jersey*, at Franklin, Hamburg, and Newton, black and brown crystals in limestone, with spinel. In *Penn.*, at Newlin, Chester Co.; at London Grove and near Unionville, of a light yellow or brownish-yellow (f. 458), in limestone, and rarely *white*; at Parksburg, Chester Co; in Delaware Co., at Aston; at Chester, fine black; Middletown, black; Marple, of a green color in talc; opposite New Hope, Buck's Co.; in New Garden township, Chester Co., in limestone, light brown to yellow and sometimes transparent; near New Hope on the Delaware, large black crystals, in which the prismatic faces are sometimes almost obsolete. In *S. Car.*, in Cheowee valley. In *Georgia*, Habersham Co. In *California*, black crystals, 6–8 in. in diameter, in feldspar veins, in the mountains between San Diego and the Colorado desert, bordering the elevated valley of San Felipe.

In *Canada*, superb greenish-yellow crystals, 1 inch through, in limestone at G. Calumet Id.; amber-colored at Fitzroy, C. W.; transparent-brown (f. 336) at Hunterstown, C. E., with idocrase and garnet; black at Bathurst and Elmsley, C. W., and St. Jerome, C. E.

The name *turmalin*, from *Turamali* in Cingalese, was introduced into Holland in 1703, with a lot of gems from Ceylon. The property of attracting the ashes of burnt peat, after friction, led to its being very soon named in Holland *Aschentrecker*, or *ash-drawer*. In 1717, Lemery, in his Memoir in the Hist. de l'Acad. des Sci., France, referred the attraction to magnetism; and in 1756 to 1762, appeared the several Memoirs of Æpinus (published in the Mem. Acad. Berlin, vol. xii., and at St. Petersburg) on the *electrical* properties of tourmaline. The name *tourmaline* was slow of introduction into mineralogical treatises. The first specimens from Ceylon were cut gems, so that the common characteristics of tourmaline and schorl were not apparent. Linnæus, in his Syst. Nat., 1768, suggests the relation between them, but de Lisle was the first to describe Ceylon crystals, and bring the two minerals into one species. On the name *schorl*, see pages 204 to 206. Long after the union of tourmaline and schorl, the species continued to bear the latter of these names; and even in 1816, Jameson, in his System of Mineralogy, retains schorl as the name of the species, with *common schorl* and *tourmaline* or *precious schorl* as two subspecies.

Alt.—Tourmaline occurs altered to mica, chlorite, cookeite, steatite. The mica is lepidolite, a species which is related in composition to some tourmaline, and is a frequent associate of the red and green varieties. It appears to take place through the addition of alkalies. Some rubellites and green tourmalines at Chesterfield are hollow, evidently from decomposition and removal of the interior; and in the cavities are occasionally observed small crystals of yellow uranite (Teschemacher).

ZEUXITE, Thomson (Ann. Phil., iv. 299, 1814) was found in 1814 in acicular interwoven crystals at Huel Unity, Cornwall; color brown, slightly greenish in some lights; G.=3·051; H.=4·25; prisms stated to be flat rectangular. Thomson's analysis afforded S̈i 33·48, A̶l 31·85, Ḟe 26·01, Ċa 2·46, Ḣ 5·28=99·07. B.B. becomes scoriaceous at the edges. Loses over 5 p. c. when heated in a glass tube. Greg supposes that this loss may have been of boric acid instead of water, and that the mineral is a ferriferous tourmaline (Phil. Mag., IV. x. 118).

321. GEHLENITE. Gehlenit *Fuchs*, Schw. J., xv. 377, 1815. Stylobat *Breith.*, Leonh. Taschenb., x. 600, 1816, Hoffm. Min., iv. b, 109, 1817.

Tetragonal; near meionite in form (p. 318). *O* ∧ 1-*i*=158° 12′; *a*=0·400. Observed planes: *O*; vertical, *i-i*, *i*-3; octahedral, 1, $\frac{8}{7}$, 2, $\frac{7}{3}$-*i*, Descl. *O* ∧ 1=150° 30′, *O* ∧ 2=131° 28′, *O* ∧ $\frac{8}{7}$=147° 7′, *O* ∧ $\frac{7}{3}$-*i*=136° 58′ (135°—136° obs.). Crystals usually short square prisms, sometimes tabular. Cleavage: *O* imperfect; *i-i* in traces.

H.=5·5—6. G.=2·9—3·067. Lustre resinous, inclining to vitreous. Color different shades of grayish-green to liver-brown; none bright. Faintly subtranslucent—opaque. Fracture uneven—splintery. Streak white—grayish-white. Double refraction feeble; axis negative.

Comp.—O. ratio for Ṙ, R̶, S̈i=1 : 1 : $\frac{4}{3}$, or 3 : 2 between bases and silica, as in andalusite. Formula ($\frac{1}{2}$ Ṙ³ + $\frac{1}{2}$ R̶) S̈i=, if A̶l to F̶e=5 : 1, Silica 29·9, alumina 21·5, sesquioxyd of iron 6·6, lime 42·0=100. Analyses: 1, Fuchs (Schw., xv. 377); 2, Thomson (Min., i. 281); 3, v Kobell (Kastn. Arch., iv. 313); 4, Damour (Ann. Ch. Phys., III. x. 66); 5, 6, Kühn (Ann. Ch. Pharm., lix. 371); 7, Rammelsberg (3d Suppl., 47):

		S̈i	A̶l	F̶e	Ḟe	Ṁg	Ċa	Ḣ
1.	Fassa	29·64	24·80	6·56		—	35·30	3·30=99·60 Fuchs.
2.	"	29·13	25·05	—	4·35	—	37·38	4·54=100·45 Thomson.
3.	"	31·0	21·4	—	4·4	3·4	37·4	2·0=99·6 Kobell.
4.	"	31·60	19·80	5·97	—	2·20	38·11	1·58, Ṅa 0·33=99·54 Damour.

6.	"	29·53	19·00	—	7·25	1·41	36·55	5·55=99·28 Kühn.
7.	"	29·78	22·02	3·22	1·73	3·88	37·90, Ḣ and loss 1·28, M̶n 0·19 Ramm.	

Rammelsberg has cleared up in part the discrepancies in the analyses by discovering that the mineral contains both *sesquioxyd* and *protoxyd* of iron. The oxygen ratio from his analyses is 3·4 : 3 : 4·1, for which he substitutes 3 : 3 : 4=1 : 1 : $\frac{4}{3}$.

Pyr., etc.—B.B. thin splinters fuse with difficulty (F.=5·7, v. Kobell) to a gray glass. With borax fuses slowly to a glass colored by iron. Gelatinizes with muriatic acid, yielding a solution containing both protoxyd and sesquioxyd of iron.

Obs.—Gehlenite is found only at Mount Monzoni, in the Fassa valley, in isolated or aggregated crystals, invested by calcite.

Named by Fuchs after his colleague, Gehlen.

Alt.—Gehlenite occurs altered to steatite. A partially altered specimen afforded G. Bischof $\ddot{\mathrm{Si}}$ 31·62, $\overline{\mathrm{Al}}$ 23·79, $\dot{\mathrm{Fe}}$ 9·43, $\dot{\mathrm{Mg}}$ 2·84, $\dot{\mathrm{Ca}}$ 31·13, ign. 1·28=100·09, with some mixed carbonate of lime.

Artif.—Not unfrequent among furnace scoria, in thin square tables, or 8-sided prisms, with cleavage parallel to the lateral planes of a square prism. Has been observed at Dawes' furnace, Oldbury in England, and at Holzhausen in Hessia. Analyses: 1, Percy (Rep. Brit. Assoc., 1846, Am. J. Sci., II. v. 128); 2, Bunsen:

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{Ca}}\,\dddot{\mathrm{S}}$	Ca S

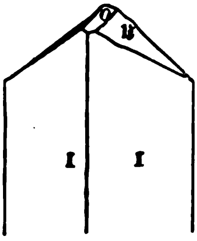
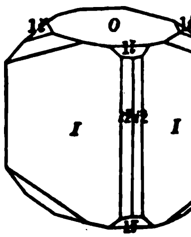
Orthorhombic. $I \wedge I = 90° \, 48'$, $O \wedge 1\text{-}\bar{\imath} = 144° \, 32'$; $a : b : c = 0·71241 : 1 : 1·01405$. Observed planes: O; vertical, I, $i\text{-}\bar{\imath}$, $i\text{-}\breve{\imath}$, $i\text{-}2$, $i\text{-}\breve{2}$; domes, $1\text{-}\bar{\imath}$, $1\text{-}\breve{\imath}$; octahedral, 1, $2\text{-}\breve{2}$. $O \wedge I = 90°$, $O \wedge 1\text{-}\breve{\imath} = 144° \, 55'$, $i\text{-}\breve{2} \wedge i\text{-}\breve{2} = 127° \, 30'$, $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath} = 109° \, 4'$, $1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath} = 109° \, 50'$. Cleavage: I perfect in crystals from Brazil; $i\text{-}\bar{\imath}$ less perfect; $i\text{-}\breve{\imath}$ in traces. Massive, imperfectly columnar, sometimes radiated, and granular.

340



Westford Mass.

341



H.=7·5; in some opaque kinds 3—6. G.=3·05—3·35, mostly 3·1—3·2. Lustre vitreous; often weak. Color whitish, rose-red, flesh-red, violet, pearl-gray, reddish-brown, olive-green. Streak uncolored. Transparent to opaque, usually substranslucent. Fracture uneven, subconchoidal. Double refraction strong; optic-axial plane $i\text{-}\breve{\imath}$; angle very large over 80°; bisectrix negative, normal to O.

Var.—1. *Ordinary.* H.=7·5 on the basal face, if not elsewhere. For sp. gr., see below.

2. *Chiastolite* (macle). Stout crystals having the axis and angles of a different color from the rest, owing to a regular arrangement of impurities through the interior, and hence exhibiting a colored

cross, or a tesselated appearance in a transverse section. H.=3–7·5, varying much with the degree of impurity. The following figures show sections of some crystals. Fig. 342, by C. T. Jackson in J. Soc. N. Hist., Bost., i. 55; figs. *a* and *b* are from opposite extremities of the same crystals; so also *c* and *d*; *e* and *f*; *h* appears to be a twin crystal.

342

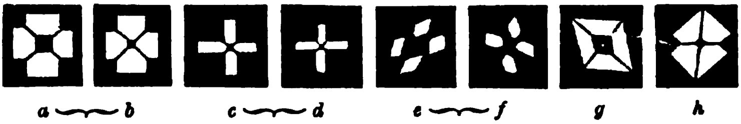


Fig. 343 shows the successive parts of a single crystal, as dissected by B. Horsford of Springfield, Mass.; 344, one of the four white portions; and 345, the central black portion. The forms of the white and black portions vary much. Bernhardi showed in 1807 (l. c.) that the central column sometimes widened *from the middle* toward each end.

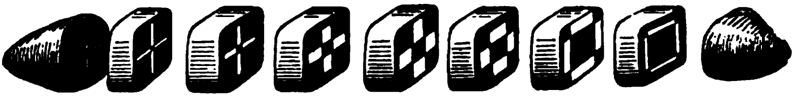
343



344

345

The name *macle* is from the Latin *macula, a spot*, and, as Robien observes, it alludes to the use of the "*mascle*" in heraldry, in which the word signifies *a voided losenge*, or a rhomb with open centre (l. c., 1751, in de Lisle, Crist.). Chiastolite is from *chi*, the Greek name for the letter X.

Comp.—O. ratio for Ṙ, S̈i=3 : 2; Ä̶l S̈i=Silica 36·8, alumina 63·2=100, with little, if any, sesquioxyd of iron replacing the alumina. Analyses: 1, Bucholz (Moll's Efem., iv. 190); 2, Thomson (Min., i. 232); 3, Bunsen (Pogg., xlvii. 186); 4. A. Erdmann (Jahresb., xxiv. 311); 5, Roth (ZS. G., vii. 15); 6–8, Hubert (Jahrb. G. Anal. No. 4, G.=3·154; 5, cyanite pseudomorphous after andalusite, G.=3·401; 6, G.=3·103 7, pseudomorphous cyanite, forming the exterior of 6, G.=3·327; 8, pseudomorphous cyanite after andalusite, from the Koralp in Styria, G.=3·648; 9, G.=3·152; 10, G.=3·12; 11, G.=3·11 12, G.=3·07; 15, G.=3·14; 17, G.=3·160; 20, G.=3·1, $I \wedge I=93\frac{1}{2}°$.

Pyr., etc.—B.B. infusible. With cobalt solution gives a blue color Not decomposed by acids Decomposed on fusion with caustic alkalies and alkaline carbonates.

Obs.—Most common in argillaceous schist, or other schists imperfectly crystalline; also in gneiss, mica schist, and related rocks; rarely in connection with serpentine. Found in Spain, in Andalusia (first loc. discovered), and thence the name of the species; in the Tyrol, Lisens valley. in large cryst. with cyanite; in Saxony, at Bräunsdorf, Robschütz, Munzig, Penig; in Moravia, at Goldenstein; Bavaria, at Lahmerwinkel, Rabenstein, Hogenau, Tillenburg, etc.; Austria, at Felling, near Krems, in serpentine; France, Dept. of Var, near Hyères; Barèges in the Pyrenees; Finland; Russia, at Schaitansk in the Ural; Makova, etc., in Nertschinsk. In Ireland at Killiney Bay, in mica schist; near Balahulish in Argyleshire: Cumberland, England. In Brazil, province of Minas Geraes, in fine crystals and as rolled pebbles.

In N. America, in *Maine* at Mt. Abraham, Bangor, Searsmont, Camden, S. Berwick. *N. Hamp.*, at White Mtn. Notch; Boar's Head, near Rye; at Charleston. *Vermont*, near Bellows Falls. *Mass.*, at Westford, abundant in cryst., sometimes rose-colored; Lancaster, both varieties; Sterling. chiastolite. *Conn.*, at Litchfield and Washington, good cryst. *Penn*, in Delaware Co., near Leiperville, large cryst.; at Marple, Upper Providence, and Springfield, good cryst.; one weighing 7½ lbs, and a group of crystals, free from the gangue. of about 60 lbs. *Calif.*, along the Churchillas rivers, San Joaquin val., at crossing of road to Ft. Miller. In *Canada*, at L. St. Francis, in reddish trl. cryst., in mica schist, both var. In *N. Scotia*, at Cape Canseau

Alt.—Andalusite occurs altered to kaolin; sometimes to mica; also to cyanite (anal. 5, 7 8); crystals being found consisting of cyanite, or mica, as a result of the alteration.

A partially altered andalusite from the Tutchaltui Mtn., Nertschinsk, afforded Jeremejef (l. c.) $\ddot{Si}$ 53·6, $\ddot{\overline{Al}}$ 43·1, $\ddot{\overline{Fe}}$ 1·01, $\dot{Mg}$ *tr.*, $\dot{Ca}$ 0·96, $\dot{Na}$ *tr.*, $\dot{K}$ 0·8, ign. 0·87=100·34; G.=2·944. The crystals were distinctly altered to a depth of 2 lines, and this part was B.B. fusible. $I \wedge I=93\frac{1}{2}°$, the surfaces not smooth.

Artif.—Formed in crystals by the action of a current of gaseous fluorid of silicon on calcined alumina, the angle $I \wedge I$ of the crystal 91°, and composition $\ddot{Si}$ 29·5, $\ddot{\overline{Al}}$ 70·2=99·7=$\ddot{\overline{Al}}^4\ddot{Si}^3$; also by the action of fluorid of aluminum on silica (Deville & Caron).

MYELIN *Breith.*, Handb, ii. 358, 1841; Talksteinmark *Freiesleben*, Mag. Orykt. Sachs., v. 131, has, as Hausmann observes, the composition of cyanite or andalusite. It is soft, having a hardness of about 2, yellowish or reddish-white to whitish color, with colorless streak. G.=2·45—2·53; a somewhat greasy feel 1, Kersten (Schw J., lxvi. 16); 2, Kussin (Ramm. Min. Ch., 581):

	$\ddot{Si}$	$\ddot{\overline{Al}}$	$\dot{Mn}$	$\dot{Mg}$
1.	37·62	60·50	0·63	0·82=99·57.
2.	36·01	63·72	—	—=99·73.

Breithaupt says that it contains 5 p. c. of water; but neither of the analyses made sustain this.

323. FIBROLITE. Faserkiesel (fr. Bohemia) *Lindacker*, Mayer's Samml. phys. Aufs., ii. 277, 1792, Bergm. J., ii. 65, 1792. Fibrolite (fr. the Carnatic) *Bournon*, Phil. Trans., 1802, 289, 335; =Bournonite *Lucas*, Tabl., ii. 216, 1813. Bucholzit (fr. Tyrol) *Brandes*, Schw. J., xxv. 125, 1819. Sillimanite (fr. Conn.) *Bowen*, Am. J. Sci., viii. 113, 1824. Wörthite *Hess*, Pogg., xxi. 73, 1830. Xenolit *Nordensk.*, Act. Soc. Sc. Fenn., i. 372, Pogg., lvi. 643, 1842. Bamlit *Erdmann*, Ak. H. Stockh., 1842, 19. Monrolite (fr. Monroe, N. Y.) *Silliman*, Am. J. Sci., II. viii. 385, 1849.

Monoclinic. $I \wedge I=96°$ to 98° in the smoothest crystals; usually larger, the faces I striated, and passing into i-2. Cleavage: i-$\bar{i}$ very perfect, brilliant. Crystals commonly long and slender. Also fibrous or columnar massive, sometimes radiating.

H.=6—7. G.=3·2—3·3. Lustre vitreous, approaching subadamantine. Color hair-brown, grayish-brown, grayish-white, grayish-green, pale olive-green. Streak uncolored. Transparent to translucent. Double refraction very strong; optic-axial plane i-$\bar{i}$; angle about 44° for the red ray; bisectrix positive, normal to O; Descl.

Var.—1. *Sillimanite.* In long, slender crystals, passing into fibrous, with the fibres separable G.=3·238, fr. Norwich, Ct., Dana; 3·232, fr. id., Brush; 3·239, fr. Yorktown, Norton.

2. *Fibrolite.* Fibrous or fine columnar, firm and compact, sometimes radiated; grayish-white to pale brown, and pale olive-green or greenish-gray. *Bucholzite* and *monrolite* are here included; the latter is radiated columnar, and of the greenish color mentioned. G.=3·24, fibrolite, Bournon; 3·19—3·21, id., Damour; 3·239, bucholzite, fr. Chester, Pa., Erdmann; 3·04—3·1, monrolite, B. Silliman; 3·075, id., Brush.

Bamlite, from Bamle, Norway, resembles the monrolite, being columnar subplumose, silky; G. =2·984, and color greenish-white or bluish-green. The analysis of Erdmann (see below) gave a large excess of silica; but L. Saemann observes that there are minute prisms of quartz among the fibres of bamlite.

Xenolite also resembles fibrolite closely, excepting in the high specific gravity, 3·58, which suggests an identity rather with cyanite. But the prisms are stated to have the angle 91°, which is the angle of andalusite; and Descloizeaux says that it is optically like fibrolite, and not like cyanite. From Petershoff, Finland, and near St. Petersburg.

Wörthite is hydrous, and appears to be a somewhat altered form. H.=7·25; color white; translucent. Optically like the above. From near St. Petersburg.

Comp.—$\ddot{\mathrm{Al}}\ \dddot{\mathrm{Si}}$, as for andalusite=Silica 36·8, alumina 63·2=100, as in Damour's analysis of fibrolite, and Connell's, Staaf's, and Silliman's of sillimanite. Damour obtained in his analysis of sillimanite 39 p. c. of silica, and others still more, showing apparently that the mineral is not always pure.

Analyses of fibrolite, etc.: 1, Chenevix (J. d. Mines, xiv. 86); 2, B. Silliman, Jr. (Am. J. Sci., II. viii. 388); 3, 4, Damour (C. R., lxi. 319); 5, Brandes (J. de Pharm., xci. 237); 6, Thomson (Ann. Lyc. N. York, iii. and Min., i. 235); 7, A. Erdmann (Ak. H. Stockholm, 1842, 19); 8, 9, B. Silliman, Jr. (l. c.); 10, Bowen (Am. Pyr., etc.—Same as given under andalusite.

Obs.—Occurs in gneiss, mica schist, and related metamorphic rocks.

Observed near Moldau and Schuttenhöfen in Bohemia (*faserkiesel*); at Fassa in the Tyrol (*bucholzite*); in the Carnatic with corundum (*fibrolite*); at Bodenmais in Bavaria; near Eger in Bohemia; Marschendorf in Moravia; in France, in the vicinity of Issoire in boulders, and also in the canton of Paulhaguet, and in the vicinity of Chavagnac and Ourouze with cyanite and corundum, and between St. Eble and Crespignac.

---

* One of Bournon's own specimens, received by Col. Gibbs (from whom the original part of the Yale Cabinet was obtained) from Count Bournon himself.

† Prof. Norton states that in his analysis the excess of alumina was probably owing to the presence of aluminate of potassa, which remained with the alumina after separating the oxyd of iron by caustic potassa; subtracting this excess, the analysis corresponds to those by Silliman.

In the United States, in *Massachusetts*, at Worcester. In *Connecticut*, at the falls of the Yantic, near Norwich, with zircon, monazite, and corundum; and at Chester, near Saybrook (*sillimanite*); at Humphreysville. In *N. York*, at Yorktown, Westchester Co., 10 m. N.E. of Sing Sing; near the road leading from Pine's Bridge to Yorktown P. Office, in distinct crystals, with monazite, tremolite, and magnetite, the crystals often running through the magnetite; in Monroe, Orange Co. (*monrolite*), with mica, garnet, magnetite, etc. In *Penn.*, at Chester on the Delaware, near Queensbury forge; in Delaware Co., in Birmingham, Middletown, Concord, Aston, Darby. In *Delaware*, at Brandywine Springs

Fibrolite was much used for stone implements in western Europe in the "Stone age" (Anal. 3, 4.)

The crystallization of sillimanite, fibrolite, bucholzite, and also of bamlite and xenolite, was first shown to be orthorhombic by Descloizeaux, on optical grounds. The terminal planes in the crystal figured by the writer (annexed figure) were rough, and, as stated in the last edition, of too doubtful import to be relied on for their angles or their indications as to the symmetry of the crystals. Afforded $O \wedge I = 105°$; $O \wedge m = 138° 30'$, $m \wedge I$, back, $= 120° 30'$.

The species approximates closely to andalusite, but appears to differ in its cleavage, that parallel to *i-ī* being very perfect, with none parallel to *I*; and in its *positive* bisectrix and much smaller optic-axial angle.

Named *fibrolite* from the fibrous massive variety; *bucholzite*, after the chemist Bucholz; *sillimanite*, after Prof. Silliman.

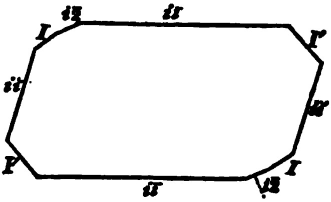
Min., ii. b, 318, 1815, iv. b, 128, 1817.

Triclinic. In flattened prisms, having the planes *i-ī*, *i-ĭ*, *I*, *I′*, *i-2*, as in the annexed transverse section (fig. 347); *O* rarely observed. Crystals oblong, usually very long and blade-like.

$O \wedge i\text{-}\breve{\imath} = 93° 15'$
$O \wedge i\text{-}\bar{\imath} = 100\ 50$
$O \wedge I' = 96\ 42$
$O \wedge I = 98\ 58$
$I \wedge i\text{-}\breve{\imath} = 122\ 21$
$i\text{-}\bar{\imath} \wedge i\text{-}\breve{\imath} = 106\ 16$

$I \wedge I' = 97° 4'$
$i\text{-}\breve{\imath} \wedge I = 140\ 35$
$i\text{-}\bar{\imath} \wedge I = 145\ 41$
$i\text{-}\bar{\imath} \wedge I' = 131\ 23$
$i\text{-}\bar{\imath} \wedge i\text{-}2 = 159\ 15$
$I \wedge i\text{-}2 = 166\ 26$

347



Cleavage: *i-ī* perfect; *i-ĭ* less so; *O* imperfect. Twins: composition-face *i-ī*, the two planes *O* and *i-ĭ* making angles with one another; either *right*-handed or *left*-handed, analogous to right- and left-handed twins of orthoclase (f. 314, 315, p. 353); also a kind having the two crystals crossing at 60°. Also coarsely bladed columnar to subfibrous.

H.=5–7·25, the least on the lateral planes. G.=3·45–3·7; 3·559, white cyanite; 3·675, blue transparent; 3·661, Tyrol, Erdmann. Lustre vitreous—pearly. Color blue, white, blue along the centre of the blades or crystals with white margins; also gray, green, black. Streak uncolored. Translucent—transparent. Optic-axial plane inclined about 30° to edge *i-ī*/*i-ĭ* and 60° 15′ to edge *i-ī*/*O*; bisectrix negative, very nearly normal to *i-ī*.

Var.—The white cyanite is sometimes called *Rhætizite*.

Comp.—$\ddot{A}l\,\ddot{S}i$=Silica 36·8, alumina 63·2=100.

12.	Lincoln Co., N. C.	37·60	60·40	1·60=99·60 Smith & Brush.

Pyr., etc.—Same as for andalusite.

Obs.—Occurs principally in gneiss and mica slate. Found in transparent crystals at St. Gothard in Switzerland; at Greiner and Pfitsch (*rhætizite*, or white variety) in the Tyrol; also in Styria; Carinthia; Bohemia; Norway; Finland; at Pontivy, France; Villa Rica, South America; in Scotland, at Botriphinie in Banffshire, at Banchory in Aberdeenshire, and near Glen Tilt; in the Shetlands at Hilswickness Point; in Ireland, at Donegal and Mayo.

In *N. Hamp.*, at Jaffrey, on the Monadnock Mtn. In *Mass.*, at Chesterfield, with garnet in mica schist; at Worthington and Blanford in good specimens; at Westfield and Lancaster. In *Conn.*, at Litchfield and Washington in large rolled masses, with corundum and massive apatite; at Oxford, near Humphreysville, in mica schist. In *Vermont*, at Thetford and Salisbury; at Bellows Falls in short disseminated crystals. In *Penn.*, in fine specimens near Philadelphia, on the Schuylkill road near the Darby bridge; near the Schuylkill, on the Ridge road, back of Robin Hood tavern; at East and West Branford, Chester Co.; at Darby and Haverford, Delaware Co. In *Maryland*, eighteen miles north of Baltimore, at Scott's mill; in Delaware near Wilmington. In *Virginia* at Willis's Mt., Buckingham Co, and two miles north of Chancellorville, Spotsylvania Co. In *N. Carolina*, on the road to Cooper's gap in Lincoln Co., near Crowder's Mtn., with lazulite. A black variety, associated with rutile, occurs in North Carolina.

Cyanite, when blue and transparent, and in sufficiently large pieces, is employed as a gem, and somewhat resembles sapphire.

Named from *κυανός*, *blue*. The name *sappare* arose from a mistake by Saussure, Jr., in reading a label of this mineral on which it was called sapphire; a copy of this label is given in J. de Phys., xxxiv. 213; the specimen thus labelled was from Botriphinie in Scotland, and was sent by the Duke of Gordon to Saussure the father. *Disthene* is from *δίς*, *twice*, or of two kinds, and *σθένος*, *strong*, alluding to the unequal hardness and electric properties in two different directions.

Von Kobell has shown (Ber. Ak. München, 1867) that the right and left-handed twins may be easily distinguished by means of polarized light; they give, with the stauroscope, a cross somewhat oblique in position; but the principal optical section does not revolve with the revolution of the crystal; while the colors change in different order with the revolution, according as the twin is right-handed or left-handed.

Alt.—Cyanite occurs altered to talc and steatite.

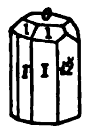
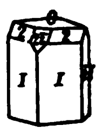
Crystals usually hemihedral, the extremities being unlike. Cleavage: basal, highly perfect. Also firm columnar; also granular, coarse or fine.

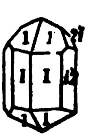
348



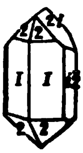
349



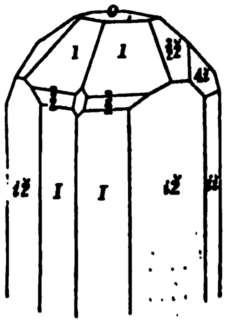
350



351

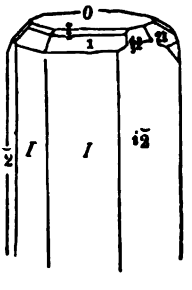


352



Trumbull, Ct.

353



Schneckenstein.

H.=8. G.=3·4—3·65. Lustre vitreous. Color straw-yellow, wine-yellow, white, grayish, greenish, bluish, reddish; pale. Streak uncolored. Transparent—subtranslucent. Fracture subconchoidal, uneven. Pyroelectric. Optic-axial plane $i\text{-}\breve{i}$; divergence very variable, sometimes differing much in different parts of the same crystal; bisectrix positive, normal to O.

Var.—1. *Ordinary*. Usually in crystals; common form prismatic. The basal cleavage is an easily observed character. Crystals from La Paz, Mexico, gave Hessenberg $I \wedge I=124°\ 26'$.

Physalite, or *pyrophysalite*, is a coarse nearly opaque variety, in yellowish-white large crystals from Finbo; it intumesces when heated, and hence its name from φυσάω, *to blow*, and πυρ, *fire*.

2. *Pycnite*. Structure columnar, but very compact. Has been considered a distinct species on the ground of composition (see anal.) and crystallization (made monoclinic by Forchhammer). But Rose has made out that the cleavage is the same, and the form probably the same; and Descloizeaux has shown that the optical characters are those of topaz. Finally, Rammelsberg's recent analysis gives the same composition. Named from πυκνός, *thick*.

Comp.—$\dddot{A}l\ddot{S}i$, with one-half of the oxygen of the silica replaced by fluorine; or, specially, $\dddot{A}l\ (\tfrac{5}{6}\,Si\,O^5+\tfrac{1}{6}\,Si\,F^5)$=Silicon 15·17, aluminum 29·58, oxygen 34·67, fluorine 20·58=100; or, Silica

16·2, silicic fluorid 28·1, alumina 55·7=100. The formula agrees with Städeler's results, which shows (J. pr. Ch., xcix. 65) that the fluorine present amounts to about 20·68 p. c. (see below).

Analyses: 1–3, Berzelius (Schweig J., xvi. 423, Afhandl., iv. 236); 4, 5, Forchhammer (J. pr Ch., xxix. 195, xxx. 400); 6–10, Rammelsberg (J. pr. Ch., xcvi. 7); 11, Bucholz (Schw. J., i 385); 12, Berzelius (l. c.); 13, Forchhammer (l. c.); 14, Rammelsberg (l. c.):

No. 10 gave 0·66 ign. Deville (C. R., lii. 782) obtained for topaz:

	$\ddot{\text{Si}}$	$\ddot{\bar{\text{Al}}}$	Si	F
1. Saxony	22·3	54·3	6·5	17·3=100·4.
2. Brazil	25·1	53·8	5·8	15·7=100·4.

Klaproth, in 1795 (Beitr., i. 10), found that pycnite lost 25 p. c. in a porcelain oven; and Forchhammer (J. pr. Ch., xxix. 194, xxx. 400) obtained for the loss, at the fusing-point of iron, of the topaz of Trumbull, Ct., 23·535 p. c.; of Brazil, 23·03; of Finbo, 24·80 H. St. Claire Deville states (C. R., xxxviii. 317) that topaz loses its fluorine as fluorid of silicon; 23 p. c. of this fluorid, in his trials, passed off. In recent experiments made under Rammelsberg's direction, the Finbo mineral lost in a porcelain oven 22·98 p. c.; Schneckenstein 20·73; Schlackenwald 17·73—16·23; Trumbull 16·27—19·55; Brazil 15·40—14·29; Altenberg pycnite 19·98. The topaz was not fused in the heating, yet somewhat blistered at surface. The Brazil topaz afforded Rammelsberg after the heating in which 15·4 p. c. were lost, $\ddot{\text{Si}}$ 30·22, $\ddot{\bar{\text{Al}}}$ 71·34, F 1·56=103·12; and after that in which the loss was 14·29 p. c., $\ddot{\text{Si}}$ 30·10, $\ddot{\bar{\text{Al}}}$ 70·38, F 2·47=102·95, showing that the part lost was not strictly fluorid of silicon, but may have included some fluorid of aluminum. G. Städeler (l. c.) has shown that part of the fluorine escapes as fluohydric acid, and makes 89·9 p. c. of the loss to be fluorine. This gives for the Trumbull topaz (anal. 5), 21·16 F; the Brazil, 20·71 F; the Finbo, 22·29, from Forchhammer's results, and 20·66 from Rammelsberg's; for the Saxon, 18·64 from Rammelsberg's trials, and 20·68 from Deville's; the mean of the whole 20·68.

Pyr., etc.—B.B. infusible. Some varieties take a wine-yellow or pink tinge when heated. Fused in the open tube with salt of phosphorus gives the reaction for fluorine. With cobalt solution the pulverized mineral gives a fine blue on heating. Only partially attacked by sulphuric acid. G. before ignition 3·539, after, 3·533, Church.

Obs.—Topaz occurs in gneiss or granite, with tourmaline, mica, and beryl, occasionally with apatite, fluor spar, and tin ore; also in talcose rock, as in Brazil, with euclase, etc., or in mica slate. With quartz, tourmaline, and lithomarge, it forms the topaz rock of Werner (*topazosème* of Haüy). Specimens of quartz crystal from Brazil, penetrated by topaz, are not uncommon.

Minute crystals of three or four different kinds, and two or three kinds of liquids, have been detected by Sir David Brewster in crystals of topaz. (Edinb. Trans., x., and Am. J. Sci., xii. 214; and later, Edinb. new Phil. J., II. xvi. 130, Proc. R. Soc. Edinb., iv. 548, v. 95.) See under Organic Compounds.

Fine topazes come from the Urals, near Katharinenburg, and Miask; in Nertschinsk, beyond L. Baikal, in the Adun-Tschilon Mts., etc., one crystal from near the river Urulga, now in the imperial cabinet at St. Petersburg, being 11⅓ in. long, 6¼ in. broad, weighing 22¼ lbs. av., and magnificent also in its perfect transparency and wine-yellow color. Found also in Kamschatka, of yellow, green, and blue colors; Villa Rica in Brazil, of deep yellow color, either in veins or nests in lithomarge, or in loose crystals or pebbles; sky-blue crystals in Cairngorm, Aberdeenshire, Jameson mentions one which weighed 19 oz.; at the tin mines of Schlackenwald, Zinnwald, and Ehrenfriedersdorf, and smaller crystals at Schneckenstein and Altenberg; the Mourne mountains, small limpid crystals with beryl, albite, and mica, in drusy cavities in granite. Physalite occurs in crystals of great size, at Fossum, Norway; Finbo, Sweden, in a granite quarry, and at Broddbo in a boulder; one crystal from this last locality, at Stockholm, weighed eighty pounds.

Topaz occurs also in the Mercado Mtn., in Durango, Mexico, along with tin ore and magnetite; at La Paz, province of Guanaxuato. *Pycnite* is from the tin mine of Altenberg in Saxony; also those of Schlackenwald, Zinnwald in Bohemia, and Kongsberg in Norway.

In the United States, in *Conn.*, at Trumbull, with fluor and diaspore; at Middletown rare; at Willimantic, with columbite. In *N. Car.*, at Crowder's Mountain. In *Utah*, near 39° 40′ N. and 113½° W., W. of S. of Salt Lake, in Thomas's Mts., on Capt. Simson's return trail. At Trumbull the crystals are abundant, but are seldom transparent, except those of small size; these are usually white, or with a tinge of green or yellow. The large coarse crystals are sometimes six or seven inches in diameter.

A variety of topaz from Brazil, when heated, assumes a pink or red hue, resembling the Balas ruby. The finest crystals are brought from Minas Novas in Brazil. From their peculiar limpidity, topaz pebbles are sometimes denominated *gouttes d'eau*. The coarse varieties of topaz may be employed as a substitute for emery.

On the cryst. of topaz, see Kokscharof, Min. Russl., ii. 198, 344, iii. 195, 378; Hessenberg, Min Not., No. vii. 38.

The name topaz is from τοπάζιος, an island in the Red Sea, as stated by Pliny. But the topaz of Pliny was not the true topaz, as it "yielded to the file." Topas was included by Pliny and earlier writers, as well as by many later, under the name *chrysolite*.

Alt.—Topaz is found altered both to steatite, and kaolin or lithomarge.

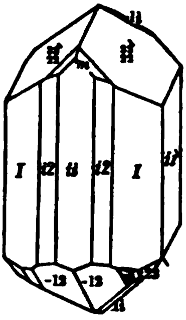
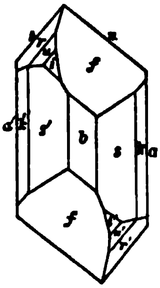
354



354A



Cleavage: $i\text{-}\grave{i}$ very perfect and brilliant; O, $i\text{-}i$ much less distinct. Found only in crystals.

H.=7·5. G.=3·098, Haid. 3·097, blue, from Brazil, Descl.; 3·096–

3·103, fr. Urals, Koksch. Lustre vitreous, somewhat pearly on the cleavage face. Colorless, pale mountain-green, passing into blue and white. Streak uncolored. Transparent; occasionally subtransparent. Fracture conchoidal. Very brittle. Double refraction strong; optic-axial plane *i-ì*; bisectrix acute, positive.

Comp.—O. ratio for $\dot{Be}$, $\dddot{\bar{Al}}$, $\ddot{Si}$, $\dot{H}$=2 : 3 : 4 : 1, from Damour's analysis, who first found water to be a constituent; whence $(\frac{1}{3}\dot{H}^3+\frac{2}{3}\dot{Be}^3+\frac{2}{3}\dddot{\bar{Al}})\ddot{Si}$=Silica 41·1, alumina 35·3, glucina 17·4, water 6·2=100. Fluorine replaces a little of the oxygen. Analyses: 1, Berzelius (Schw. J., xxvii. 73); 2, Mallet (Phil. Mag., IV. v. 127); 3, Damour (C. R., xl. 942):

	$\ddot{Si}$	$\dddot{\bar{Al}}$	$\dddot{\bar{Fe}}$	$\dot{Fe}$	$\dot{Be}$	$\dot{Ca}$	$\ddot{Sn}$	$\dot{H}$	F	
1.	43·22	30·56	2·22	—	21·78	—	0·70	—	—	=98·48 Berzelius.
2.	44·18	31·87	1·31	—	21·48	—	0·35	—	—	=99·14 Mallett.
3. (½)	41·63	34·07	—	1·03	16·97	0·14	0·34	6·04	0·38	=100·60 Damour

Pyr., etc.—In the closed tube, when strongly ignited, B.B. gives off water (Damour). B.B. in the forceps cracks and whitens, throws out points, and fuses at 5·5 to a white enamel. Becomes electric by friction, and, when once excited, retains this property for several hours. Not acted on by acids.

Obs.—Occurs in Brazil, in the mining district of Villa Rica, with topaz in chloritic schist; in the auriferous sands of the Orenburg district, southern Ural, near the river Sanarka, with topaz, corundum, cyanite, etc. One Ural crystal measures 3 in. by ¾ in.

The crystallization of this species is elaborately detailed by Schabus in the Transactions of the Royal Academy of Vienna, vol. vi., and by Kokscharof in Pogg., ciii. 348, and his Russian Mineralogy.

Euclase receives a high polish, but is useless as an ornamental stone on account of its brittleness.

Named by Haüy from εὖ, *easily*, and κλάω, *to break*. Haüy states that his name, Euclase. was published by Daubenton in an early issue of his Tableau meth. de Minéraux; but the particular edition of the Tableau (of which several were issued) the author has not been able to learn. Delametherie, after publishing, in 1792, the name and description, without crediting either to Haüy, in his *Théorie de la Terre*, in 1797, gives Haüy full credit.

First brought to Europe from S. America by Dombey, in 1785.

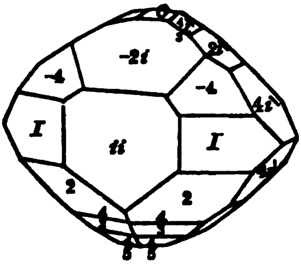
Andreasberg.

360



Toggiana.

H.=5—5·5. G.=2·8—3; 2·989, Arendal, Haidinger. Lustre vitreous, rarely subresinous on a surface of fracture; color white; sometimes grayish, pale green, yellow, red, or amethystine, rarely dirty olive-green or honey-yellow. Streak white. Translucent; rarely opaque white. Fracture uneven, subconchoidal. Brittle. Plane of optical axis $i\text{-}\breve{\imath}$; angle of divergence very obtuse; bisectrix nearly normal to $i\text{-}i$.

Var.—1. *Ordinary*. In crystals, glassy in aspect. Usual forms as in figures. Crystals from Bergen Hill, examined by Hessenberg (Min. Not., No. iv.), similar to fig. 355, but wanting O, $-8\text{-}\breve{2}$, $-6\text{-}8$, and having $i\text{-}\breve{\imath}$, $6\text{-}i$, $i\text{-}\breve{2}$. Those of Andreasberg have the planes O, $i\text{-}i$, I, $i\text{-}\breve{2}$ (these three quite small); -1-ĭ, -2-ĭ, -4-ĭ, i-ĭ, 2-ĭ; 2-ì, 4-ì, -4, -8, 2, ⅓, ½, -4-2̀, -3-2̀, -⅓-2̀, 2-2̀, 1-2̀. (Schröder Pogg., xcviii. 34, and Dauber, ib., ciii. 116). Those of Toggiana, as in fig. 360, with also i-ì, i-⅔, -8-ĭ, 1-ĭ, 4, ⅙, -6-3, -5-⅚. One of Glen Farg, figured by Greg & Lettsom, has the planes of the rhombic prism *I* (*d*) very large, i-ĭ (*P*) narrow linear, the clinodomes 2-ì, 4-ì narrow, and the octahedral planes -4 (small), ⅓ (large), 1, 2.

The plane i-ĭ is usually made *O*, and *O*, i-ĭ, and 4-ì, *I*; but in that case the form is not so simply presented as in the above figures. The angles of the vertical prisms *I*, i-2̀ are very nearly identical with those of the clinodomes 2-ì, 4-ì. The small letters added to the crystallographic symbols in the list of observed planes above, are the lettering of Brooke & Miller (Min., 408) and of Dauber. The plane *t*, of fig. 358, makes parallel intersections with ⅓ and 4-ì, but not with 2 and 2-ì. *O* ∧ *t*= 140°-142°, i-ì ∧ *t*= about 109½° by measurement.

2. *Compact massive.* White opaque, breaking with the surface of porcelain or Wedgewood ware. G.=2·911, Hayes; 2·983, Chandler. From the L. Superior region (anal. 8).

3. *Botryoidal; Botryolite.* Radiated columnar, having a botryoidal surface, and containing more water than the crystals. The original locality of both the crystallized and botryoidal was Arendal, Norway.

Comp.—O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\ddot{Si}$, $\dot{H}$=2 : 3 : 4 : 1; ($\dot{Ca}^2$, $\dot{H}^2$, $\dddot{B}$)$\ddot{Si}$, in which $\dot{H}^2$: $\dot{Ca}^2$: $\dddot{B}$=1 : 2 : 3=Silica 37·5, boric acid 21·9, lime 35·0, water 5·6=100. For botryolite, the ratio 2 : 3 : 4 : 2.

Analyses: 1, Stromeyer (Pogg., xii. 157); 2, Du Menil (Schw. J., lii. 364); 3, 4, Rammelsberg (Pogg., xlvii. 175); 5, Bechi (Am. J. Sci., II. xiv. 65); 6, Tschermak (Kenng. Uebers., 1860, 57); 7, Whitney (Am. J. Sci., III. xv. 435); 8, C. F. Chandler (ib., xxxviii. 13); 9, A. A. Hayes (J. N. H. S., Boston, viii. 62); 10, Rammelsberg (l. c.):

10. Arendal, *Botryolite*	36·08	19·34	35·22	8·63=99·27 Rammelsberg.

Pyr., etc.—In the closed tube gives off much water. B.B. fuses at 2 with intumescence to a clear glass, coloring the flame bright green. Gelatinizes with muriatic acid.

Obs.—Datolite is found in trappean rocks; also in gneiss, dioryte, and serpentine; in metallic veins; sometimes also in beds of iron ore. Found in Scotland, in trap, at Kilpatrick Hills, Glen Farg in Perthshire, and in Salisbury Craigs; in a bed of magnetite at Arendal in Norway, and in Utö in Sweden; at Andreasberg, in veins of silver ores, in argillaceous schist, with apophyllite, etc.; at Niederkirchen and Sonthofen in Bavaria (the *humboldtite*); in granite at Baveno near Lago Maggiore, one crystal from which place measured 4¼ × 3¾ × 1¼ inches; at the Seisser Alp, Tyrol, and also at Theiss, near Claussen; at Mt. Catini, Tuscany, in gabbro; at Toggiana in Modena, in serpentine; in dioryte, on the Rosskopf, near Freiburg, in Brisgau.

Datolite occurs crystallized and massive at the Rocky Hill quarry, Hartford, Conn., in the north-east part of Southington, near Mr. Hamlen's, in amygdaloid, both in crystals, fibrous, and massive; also in Berlin, near Kensington; in the north-west part of Meriden and at Middlefield Falls, Conn; in better specimens at Roaring Brook, 14 miles from New Haven, where the crystals (f. 355–356) are sometimes half an inch long, and nearly pellucid; the author obtained from a transparent crystal of this locality *I* ∧ *I*=115° 12′, giving by calculation for i-2̀ ∧ i-2̀ 76° 28′; the plane *s* is not quite even, and is often unpolished; in N. Jersey, at Bergen Hill, in splendid crystals; in trappean rocks, both crystals and the opaque white compact variety (anal. 8), in the Lake Superior region, at the Minnesota, Quincy, Marquette, Ash-bed, and other mines; at the Superior mine near Ontonagon, and on Isle Royale.

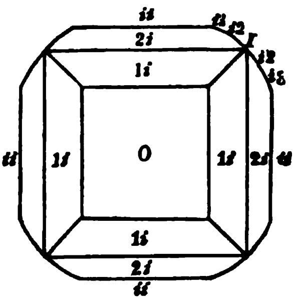
Named from δατεῖσθαι, *to divide*, alluding to the granular structure of a massive variety. Werner introduced an *h* after the first *t* without reason, and most subsequent authors have followed him in this; but not Karsten, nor Leonhard who pronounced it wrong, nor Haidinger, Aikin, Jameson, and others.

Levy gave the name *humboldtite* to crystals which he found to be *monoclinic*, datolite having been made orthorhombic by Haüy. Wollaston proved their identity with datolite.

Alt.—Haytorite is datolite altered to chalcedony.

328. GUARINITE. *Guiscardi*, ZS. G., x. 14, 1858.

362



Tetragonal. *O* ∧ 1-*i*=159° 38′; *a*=0·3712. Observed planes as in the figure. *O* ∧ 2-*i*= 143° 33′, *i-i* ∧ 1-*i*=110° 22′, *i-i* ∧ 2-*i*=126° 27′, *i-i* ∧ *i*-2=153° 26′, *i-i* ∧ *i*-3=161° 27′. In thin tables; fig. 362 a top view; planes *i-i* sometimes wanting; 1-*i* and 2-*i* observed in only one of the two zones. Cleavage parallel to *i-i*, rather imperfect.

H.=6. G.=3·487. Lustre of cleavage-face somewhat adamantine. Color sulphur-yellow, honey-yellow, pale or dark. Streak uncolored, or whitish-gray. Transparent to translucent.

Comp.—$(\dot{C}a+\ddot{T}i)\,\ddot{S}i$, same as for titanite. Analysis by Guiscardi (l. c.): $\ddot{S}i$ 33·64, $\ddot{T}i$ 33·92, $\dot{C}a$ 28·01, F̶e, M̶n *tr*. The compound is consequently *dimorphous*.

Pyr., etc.—The same as in titanite.

Obs.—Found in small cavities in a grayish trachyte, on Monte Somma, along with glassy feldspar and nephelite. The mass of the trachyte is rich in glassy feldspar, hornblende, and melanite. In one case in the common rock of Somma, consisting of feldspar and nephelite, and here along with sphene.

As titanic acid itself is trimorphous, it is not strange that a compound containing it should be dimorphous.

329. TITANITE.

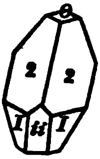
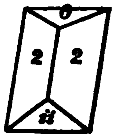
363

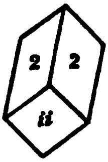


Semeline.

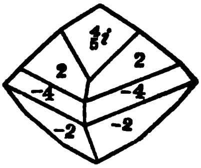
364



365

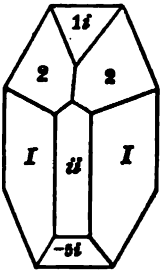


366



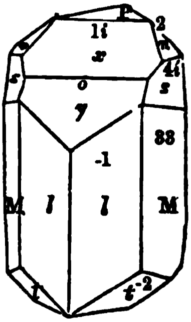
Greenovite.

367

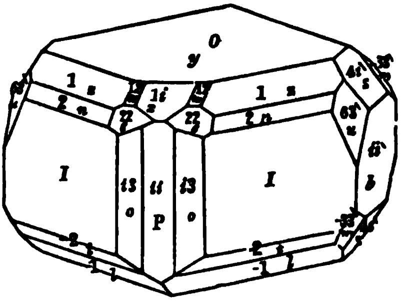


Spinthere.

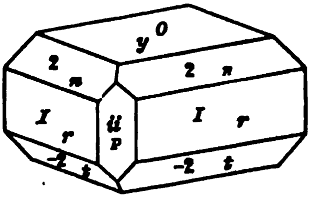
368



370



369



Lederite.

Cleavage: *I* sometimes nearly perfect; *i-i* and –1 much less so; rarely (in greenovite) 2 easy, –2 less so; sometimes hemimorphic (f. 372). Twins: composition-face *i-i*, and twinned either (*a*) by revolution on an axis normal to *i-i*, or (*b*) on a vertical axis; the former very common, and usually producing thin tables with a reëntering angle along one side; sometimes elongated, as in f. 373; occasionally in double twins, or fours, as would be represented by two f. 373 united back to back. Sometimes massive, compact; rarely lamellar.

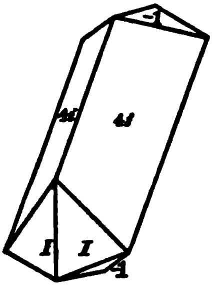
H.=5–5·5. G.=3·4–3·56. Lustre adamantine—resinous. Color brown, gray, yellow, green, and black. Streak white, slightly reddish in greenovite. Transparent—opaque. Brittle. Optic-axial plane *i-ì*; bisectrix positive, very closely normal to 1-*i* (*x*); double refraction strong; axial divergence 53°–56° for the red rays, 46°–45° for the blue; Descl.

Comp., Var.—$(\dot{C}a+\ddot{T}i)\ \ddot{S}i$, which is equivalent to $\ddot{\bar{R}}\ \ddot{S}i$ (since $R\,O+R\,O^2=R^2O^4$); it being a 3 : 2 silicate, like andalusite, but one in which titanium forms part of the base.

Var. 1. *Ordinary*. (*a*) *Titanite*; brown to black, the original being thus colored also opaque or subtranslucent. (*b*) *Sphene* (named from σφήν, *a wedge*); of light shades, as yellow, greenish, etc., and often translucent; the original was yellow.

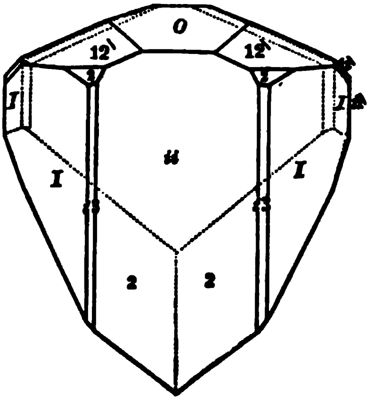
Ligurite was an apple-green sphene; *Spinthere* (or Semeline) a greenish; named *spinthere* from its lustre, and *semeline* from *semen lini*, *flax-seed*, alluding to a common form. *Lederite*, brown, opaque, or subtranslucent, of the form in f. 369.

371



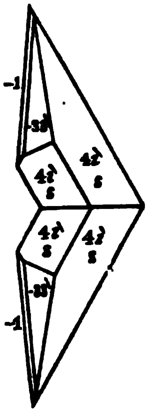
Picitite.

372



Rothenkopf.

373



Schwarzenstein.

2. *Manganesian*; *Greenovite*. Red or rose-colored, owing to the presence of a little manganese.

3. In the crystals there is a great diversity of form, arising from an elongation or not into a prism, and from the occurrence of the elongation in the direction of different diameters of the fundamental form. (*a*) Long prismatic in the direction of the prism *I*, f. 367 of *spinthere*, from Dauphiny; short prismatic, in the same direction, f. 369, *lederite*, from northern New York; (*c*) oblong prismatic in the direction of the edge 2 / 2, very common, f. 363–365; (*d*) in the direction of the edge -1 / -1, f. 368 (from Naumann); *e* in the direction of the prism 4-*i*, f. 371, pictite, and f. 373 twin from Schwarzenstein; (*f*) not elongated, of which f. 366 is one example among many widely different. Besides these there are (*g*) *hemimorphic* forms, as in f. 372, the planes of the opposite extremities of the crystal being unlike.

Analyses: 1, Klaproth (Beitr., i. 245); 2, 3. Rosales and Brooks (Pogg., lxii. 253); 4, Fuchs, (Ann. Ch. Pharm., xlvi. 319); 5, H. Rose (Pogg., lxii. 253); 6, Marignac (Ann. Ch. Phys., III. xiv. 47); 7, Delesse (Ann. d. Mines, IV. vi. 325); 8, T. S. Hunt (Am. J. Sci., II. xv. 442); 9, Arppe (Anal. Finske Min., 34):

Pyr., etc.—B.B. some varieties change color, becoming yellow, and fuse at 3 with intumescence, to a yellow, brown, or black glass. With borax they afford a clear yellowish-green glass. Imperfectly soluble in heated muriatic acid; and if the solution be concentrated along with tin, it becomes of a fine violet color. With salt of phosphorus in R.F. gives a violet bead; varieties containing much iron require to be treated with the flux on charcoal with metallic tin. Completely decomposed by sulphuric and fluohydric acids.

Obs.—Titanite occurs in imbedded crystals, in granite, gneiss, mica schist, syenite, chlorite schist, and granular limestone; also in beds of iron ore, and volcanic rocks, and often associated with pyroxene, hornblende, chlorite, scapolite, zircon, etc. Found in complicated compound crystals of a pale green color and transparent, in the Grisons, Switzerland, associated with feldspar and chlorite; in mica slate at St. Gothard; also at Mont Blanc, and elsewhere, in the Alps; on crystals of calcite at Chalanches and Maromme, in Dauphiny (the *spinthère* H.); in small reddish crystals in the protogine of Pormenaz and Chamouni (*pictite* Saus.); in large, broad, yellowish or reddish-green crystals, with colorless apatite, in a talcose schist at Ala, Piedmont (*ligurite*); in pale yellowish-green transparent or translucent crystals, laceolate in form, lining fissures in titanic iron at Arendal, in Norway (*aspidelite* Weibye); at Achmatovsk, Urals; at St. Marcel, in Piedmont, with manganesian epidote and romeine (*greenovite* Duf., anal. 6, 7); at Val Maggia, Piedmont; at Schwarzenstein, Tyrol; at Felberthal in Pinzgau; at Frugard, in Finland, of a brownish-black color (anal. 9). Small crystals occur in syenite at Strontian in Argyleshire, near Criffel in Galloway; at Craig Cailleach in Perthshire; in Inverness; near Tavistock: near Tremadoc, in North Wales, with brookite; at Crow Hill, near Newry, Ireland.

Occasionally it is found among volcanic rocks, as at Lake Laach (*semeline* of F. de Bellevue), and at Andernach on the Rhine.

Occurs in *Canada* at Grenville, Elmsley, Burgess, and Grand Calumet Island, in amber-colored crystals; in the trachytes of Yamaska, Shefford, and Brome Mts. In *Maine*, in fine crystals at Sanford, also at Thurston. In *Mass.*, good crystals in gneiss, in the east part of Lee; at Bolton with pyroxene and scapolite in limestone; at Pelham. In *Conn.*, at Trumbull. In *N. York*, at Roger's Rock on Lake George, abundant in small brown crystals, along with graphite and pyroxene; at Gouverneur, in black crystals in granular limestone with scapolite; in Diana near Natural Bridge, Lewis Co., in dark brown crystals, among which is the variety *lederite* (f. 369), in which cleavage is distinct parallel to *I*; the crystals are sometimes nearly three inches square; at Rossie, St. Lawrence Co., in pale red and brown crystals with apatite, pargasite, and feldspar; in Macomb near Pleasant Lake; in Orange Co., in large crystals abundant in limestone, near Duck-cedar pond, in the town of Monroe; near Edenville, in light brown crystals, sometimes nearly two inches across, in limestone; five miles south of Warwick, in large grayish-brown crystals, with zircon, hornblende, and iron ore; also in small crystals a mile south of Amity; in Westchester Co., near Peekskill, in an aggregate of feldspar, quartz, and hornblende; also near West Farms, in small reddish-brown prisms. In *N. Jersey*, at Franklin, of a honey-yellow color. In *Penn.*, Bucks Co., three miles west of Attleboro', associated with tabular spar and graphite.

The crystallization was first clearly made out by G. Rose in 1821. For recent observations see R. & M. Min.; Descl. Min.; Hessenberg Min. Not., Nos. i. to vii; v. Rath., Pogg., cxv. 466. Breithaupt states that much sphene is triclinic (Handb., ii. 744, B. H. Ztg., xxv. 107). Fig. 370 above is ideal, being intended to exhibit the relative positions of the planes on the fundamental prism, and the letters used on the planes by authors, as well as the symbols. Fig. 368 is from Naumann, drawn after his view of the fundamental form; and fig. 373 (from Hessenberg) is similar in this respect, but a side view.

Alt.—Sphene occurs of little hardness, dull in lustre, and hydrated from alteration. Crystals of this kind, found in a decomposing feldspar, with zircon at Green River, Henderson Co., N. C., have been named by C. U. Shepard (Am. J. Sci., xxii. 96, 1856) *Xanthitane*. Color pale yellowish-white; H.=3·5; G.=2·7—3·0, and stated to contain 12·5 p. c. of water. Also occurs altered to steatite.

Artif.—Formed in crystals by heating together 3 $\ddot{\text{Si}}$, 4 $\ddot{\text{Ti}}$, and chlorid of calcium, the composition of them ($\frac{4}{3}$) $\ddot{\text{Si}}$ 30·5, Ti 41·7, $\dot{\text{Ca}}$ 27·8=100; and the manganesian (greenovite) by adding chlorid of manganese (Hautefeuille).

330. **Grothite** *Dana*. (Titanite *P. Groth*, Jahrb. Min., 1866, 44.) P. Groth has shown that the titanite-like mineral, from the syenite of Plauen Grund near Dresden, differs in composition and cleavage from ordinary sphene. The form is monoclinic in habit, being somewhat like f. 363 and 367; but there is distinct cleavage parallel to one 2, and little distinct parallel to the other. The angles are 2 ∧ 2=136°; 2 on 1-*i*=155° 19′ to 156° 20′; 1-*i* on *i*-*i* about 162°. H.=6·5. G.=3·52—3·60. Lustre vitreous to greasy. Color clove to blackish-brown; in thin splinters reddish-brown and translucent. The altered mineral is isabella-yellow to pale yellowish-brown.

Composition according to Groth (l. c.): ($\frac{4}{3}$) $\ddot{\text{Si}}$ 30·51, $\ddot{\text{Ti}}$ 31·16, $\bar{\text{Fe}}$ 5·83, $\ddot{\bar{\text{Al}}}$, $\dot{\text{Y}}$ 2·44, Mn [illegible]2, $\dot{\text{Ca}}$ 31·34=102·30. It gives the O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Ti}}$, $\ddot{\text{Si}}$, 8·95 : 3·23 : 12·16 : 16·15, or for bases ($\ddot{\text{Ti}}$ included) to silica, 24·34 : 16·15=3 : 2. The general formula is therefore ($\dot{\text{R}}^3$, $\text{R}^{\frac{3}{2}}$, $\bar{\text{R}}$) $\ddot{\text{Si}}$. The analysis corresponds very nearly to 8 $\ddot{\text{Si}}$, 6 $\ddot{\text{Ti}}$, 1 $\bar{\text{R}}$, 9 ($\dot{\text{Ca}}$ $\dot{\text{Mn}}$). It is therefore a titanite in which one-half of the bases consists of 3 $\dot{\text{Ca}}^3$ + 1 ($\bar{\text{Fe}}$, $\ddot{\bar{\text{Al}}}$). If not a result of alteration, and the character of the cleavage is a constant one, it should rank as a distinct species.

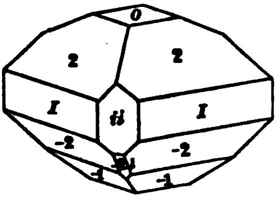
Castellite. Castellit *Breith.*, B. H. Ztg., xxv 118, 1866. Monoclinic. In very small and exceedingly thin 8-sided tables, having for the angles of the rhombic prism 118° and 62°. Cleavage prismatic? H.=5·5—6. G.=3·150. Lustre vitreous, somewhat adamantine. Color wine-yellow to wax-yellow; streak colorless. Fragile.

According to Plattner it acts B.B. like titanite, giving evidence of the presence of titanic acid, lime, and silica, but with less of the first and more of the last than in sphene. Occurs in the phonolite of Holenkluk Mtn., near Proboscht, and in that of Sollodiz—a rock containing also sanidin, hornblende, augite, ilmenite, and apatite.

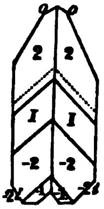
331. KEILHAUITE. Keilhauit *A. Erdmann*, Ak. H. Stockh., 355, 1844. Yttrotitanit *Scheerer*, Pogg., lxiii. 459, 1844.

Monoclinic, and near sphene in angles. $C = O \wedge i\text{-}i = 122°$, $I \wedge I = 114°$ (calc. from $I \wedge i\text{-}i$) (fig. 374); $I \wedge i\text{-}i = 147°$, $O \wedge 2 = 143°\ 30'$, $I \wedge 2 = 153°\ 30'$, $-2 \wedge -1 = 149°$, $i\text{-}i \wedge 2\text{-}i = 125°$, from measurements with the common goniometer by D. Forbes; $O \wedge I = 114°\ 26'$, and $O \wedge -1 = 140°\ 42'$, from calculations by Hansteen; faces of the crystals rather rough. Twins very common: plane of composition $i\text{-}i$ (fig. 375). Cleavage quite distinct, parallel to 2.

374



375



H.=6·5. G.=3·519 to 3·72, D. Forbes; 3·69, Scheerer; 3·716—3·733, Rammelsberg. Lustre vitreous to resinous. Brownish-black; in splinters brownish-red and translucent; also dull brown and pale grayish-brown. Streak-powder grayish-brown to pale dirty yellow.

Comp.—$(\dot{R}^3, \dddot{R}^{\frac{3}{2}}, \dddot{\bar{R}})\dddot{Si}$, having, like sphene, titanium among the basic metals; but containing the sesquioxyd alumina, and traces of glucina, and, besides lime, the protoxyds, yttria, protoxyd of iron, etc.

Analyses: 1, 2, Erdmann (l. c.); 3, D. Forbes (Edinb. N. Phil. J., II., i. 62, and iii.); 4, 5, Rammelsberg (Pogg., cvi. 296):

	$\dddot{Si}$	$\ddot{Ti}$	$\dddot{\bar{Al}}$	$\dddot{\bar{Fe}}$	$\dddot{\bar{Mn}}$	$\dddot{\bar{Ce}}$	$\dddot{\bar{Be}}$	$\dot{Ca}$	$\dot{Y}$
1.	30·00	29·01	6·09	6·35	0·67	0·32	—	18·92	9·62=100·98 Erdmann.
2.	29·45	28·14	5·90	6·48	0·86	0·63	—	18·68	9·74=99·88 Erdmann.

4. *Massive*	29·48	26·67	5·45	6·75	*tr.*	—	—	20·29	8·16, Mg 0·94, $\dot{K}$ 0·60, ign. 0·54=98·88 Ramm.
5. *Cryst.*	28·50	27·04	6·24	5·90	*tr.*	—	—	17·15	12·08, $\dot{Mg}$ *tr.*, ign. 3·59=100·50 Ramm.

Rammelsberg's analyses afford for the oxygen ratio between silica and the other ingredients, anal. 4, 15·72 : 22·94=2 : 3, and anal. 5, 15·20 : 22·71=2 : 3; conforming to the other analyses in the fundamental ratio of the species.

Pyr., etc.—B.B. fuses with intumescence easily to a black shining glass. Yields an iron-colored glass with borax, which in the inner flame becomes blood-red. With salt of phosphorus gives an iron color and a silica skeleton, and in the inner flame a violet bead. Reaction of manganese with soda. Decomposed by muriatic acid.

Obs.—Occurs near Arendal, Norway; at Buöe, Arkeröe, Alve, and Narrestöe, in a feldspathic rock, both in crystals and massive. Crystals weighing 2¼ lbs., and masses of 15 to 20 lbs., are mentioned by Forbes. A dull brown massive kind from Alve gave G.=3·72; and a pale grayish-brown 3·603; a specimen from near Narrestöe, G.=3·519. The Alve keilhauite has two cleavages inclined to one another 138° (Forbes & Dahl, Nyt. Mag. f Nat., xiii.). Also from Snarum, Norway.

Named after Prof. Keilhau of Norway.

332. TSCHEFFKINITE. ? Mineral de Coromandel *Beud.*, Tr., ii. 652, 1832. Tschewkinit *G. Rose*, Reis. Ural, ii. 1839.

Massive, amorphous.

H.=5—5·5. G.=4·508—4·549, G. Rose; 4·5296, H. Rose; after heating, in powder, 4·615; after fusion, 4·717. Lustre vitreous. Color velvet-black. Streak dark brown. Subtranslucent to opaque.

Comp.—Essentially $(\dot{R}^3, \ddot{R}^{\frac{3}{2}}, \bar{R})\ddot{Si}$, for the Ural tscheffkinite, as in keilhauite. Analyses: 1 H. Rose (Pogg., lxii. 591); 2, Hermann (Bull. Soc. Nat. Moscou, xxxix. 57); 3, Beudant (Tr., l. c.); 4, A. Damour (Bull. G. Fr., xix. 550, 1862):

Hermann showed that the mineral contained thoria, and that Rose had included it in his titanic acid and oxyd of cerium; his O. ratio for $\dot{R}$ (including the thoria), $\ddot{Ti}$, $\ddot{Si}$ is 10·44 : 6·38 : 10·92 = 15 : 9 : 16, and hence for $\dot{R}+\ddot{R}$, $\ddot{Si}$, 3 : 2, whence the above formula. Rose's analysis corresponds to the same general formula.

a. The Coromandel mineral, referred here by Damour, affords, according to him, the O. ratio for $\dot{R}+\bar{R}+\ddot{R}$, $\ddot{Si}=2:1$; and for $\dot{R}$, $\bar{R}$, $\ddot{R}=2:1:2$; whence the formula $(\frac{2}{3}\dot{R}^3+\frac{1}{6}\bar{R}+\frac{1}{6}\ddot{R}^{\frac{3}{2}})^4\ddot{Si}^2$. The alumina is left out of consideration as an impurity. But including it, the O. ratio for bases and silica is 20·65 to 10·14, sustaining still better the ratio 2 : 1. Damour has made a new examination of the mineral, and directly ascertained the *absence of thorium* (letter to the author of April 24, 1867); he further observes that a little $\dot{Di}$ and $\dot{La}$ are probably present with the $\dot{Ce}$. Descloizeaux states that the mineral is not homogeneous, it consisting of a brown material not acting on polarized light, and small colorless grains which are strongly doubly refracting. The mineral has H.=5·5—6; G.=4·26; lustre vitreous, inclining to resinous; color brownish-black subtranslucent.

Pyr., etc.—B.B. glows, then intumesces strongly, becomes brown, and fuses to a black glass Gives with the fluxes reactions for iron, manganese, and titanic acid. Gelatinizes with muriatic acid. The Coromandel mineral in a closed tube yields a little water. B.B. fuses with intumescence to a black scoria, feebly magnetic. With salt of phosphorus it gives in R.F. a pale brown glass, opaline, which becomes milky in the O.F. With borax it affords a hyacinth-brown glass, transparent in the R.F. and pale brown and opaque in the O.F. Attacked readily by nitric acid, especially if heated, depositing gelatinous silica mixed with titanic acid and black grains of titanic iron.

Obs.—From the Ilmen Mountains in the Urals; only a few specimens have been found. The tscheffkinite in collections is mostly *uralorthite*, which it much resembles. Also from the coast of Coromandel, whence it was long since brought by Leschenault.

Named after the Russian general, Tschevkin.

333. **STAUROLITE.** Pierres de croix *de Robien*, N. idées sur la format. d. Foss., 109, 1751 (with figs.). Basaltes crystallisatus pt. *Cronst.* (the specimen a cross of two brown 6-sided crystals, worn as an amulet at baptisms in Basel, and called *Lapis crucifer*, and *Basler Taufstein*), Min., 70, 1758. Orthorhombic. $I \wedge I=129° 20'$, $O \wedge 1\text{-}\bar{i}=124° 46'$; $a:b:c=1·4406 : 1 : 2·11233$. Observed planes: O; vertical, I, $i\text{-}\breve{i}$; dome, $1\text{-}\bar{i}$.

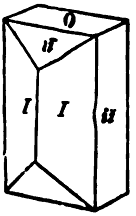
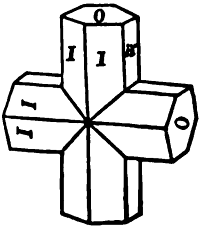
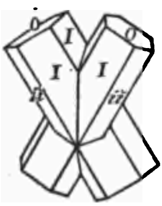
376



377



378



$O \wedge 1\text{-}\bar{i}=124° 46'$
$O \wedge I=90$
$O \wedge i\text{-}\breve{i}=90$
$I \wedge i\text{-}\breve{i}=115\ 17$
$O \wedge \frac{3}{2}\text{-}\breve{i}$, comp.-face, $=134\ 21$
$O \wedge \frac{3}{2}\text{-}\breve{\frac{3}{2}}$ " $=119\ 23$
$I \wedge I$, meas., 128 30–129 30

Cleavage: $i\text{-}\breve{i}$ distinct, but interrupted; I in traces

Twins cruciform: 1, composition-face $\frac{3}{2}\text{-}\breve{i}$ (f. 377); 2, composition-face $\frac{3}{2}\text{-}\breve{\frac{3}{2}}$.

(f. 378). [Making $\frac{3}{2}$-$\breve{i}$ and $\frac{3}{2}$-$\frac{3}{2}$ the planes 1-$\breve{i}$ and 1, on the ground that twinning usually takes place parallel to the fundamental or diagonal planes of crystals, then I above is i-$\frac{3}{2}$, and the true $I \wedge I=109° 14'$, whence $a' : b' : c' =$ 1·4406 : 1 : 1·4082 ($=\frac{3}{2} c$).] Crystals often with rough surfaces. Massive forms unobserved.

H.=7—7·5. G.=3·4—3·8. Subvitreous, inclining to resinous. Color dark reddish-brown to brownish-black, and yellowish-brown. Streak uncolored to grayish. Translucent—nearly or quite opaque. Fracture conchoidal. Optic-axial plane i-$\bar{i}$; bisectrix positive, normal to O.

Comp., Var.—O. ratio for $\dot{R}(+\dot{H})$, $\overline{R}$, $\ddot{Si}$=1 : 4 : 2½; for bases and silica 2 : 1; whence $(\frac{1}{5}\dot{R}^3+\frac{4}{5}\overline{Al})^4\ddot{Si}^3$= (if $3\dot{R}=\frac{3}{4}\dot{H}+\frac{2}{4}\dot{Mg}+\frac{7}{4}\dot{Fe}$) Silica 28·3, alumina 51·7, protoxyd of iron 15·8, magnesia 2·5, water 1·7=100. Excluding the water, the formula may be $(\dot{Fe}^3, \overline{Al})^4\ddot{Si}^3+\frac{1}{4}\dot{R}^3\ddot{Si}$, equivalent to a 2 : 1 silicate containing a little $(\dot{Mg}, \dot{Fe})^2\ddot{Si}$ (chrysolite); or $(\dot{Fe}^3, \overline{Al})^4\ddot{Si}^3+\frac{2}{13}(\dot{R}^3, \overline{Al})\ddot{Si}$, that is, the same 2 : 1 silicate with a little gehlenite.

The early analysts made the iron all sesquioxyd. Mitscherlich has pronounced it (J. pr. Ch., lxxxvi. 1) *all* protoxyd in the staurolite of St. Gothard, Airolo, and Brittany. Rammelsberg found a variety of ratios in his analyses of the mineral from other localities, the silica varying from 27 to over 50 per cent. But G. Lechartier has ascertained that staurolite contains, uniformly, some water, separable only at a high heat; and that the variations are due to *impurities*, the powder under the microscope being distinctly a mixture of two or more minerals, and the action of fluohydric acid on some crystals making them cellular, or even spongy and fragile. After purifying the staurolite, the proportion of silica was nearly constant, and the specific gravity was 3·70—3·76 (See below.)

Var. 1. *Ordinary*. 2. *Zinc-Staurolite* (anal. 27); found at Canton, Ga., in slender crystals, ½ in long and a line or less thick, having a yellowish-brown to cinnamon-brown color; G.=3·792. The crystals have the planes I, O, i-$\bar{i}$. 3. *Manganese-Staurolite*, *Nordmarkite* (anal. 28); from dolomite in Nordmark, Sweden, of chocolate-brown color, with H.=6·5, G.=3·54, and presenting the usual crystalline form. Its easy fusibility is reason for here giving this variety the distinctive name *Nordmarkite*.

Analyses: 1, Klaproth (Beitr., v. 80); 2, Lohmeyer (Pogg., lxii. 419); 3, Marignac (Ann. Ch. Phys., III. xiv. 49); 4–7, Jacobson (Pogg., lxii. 419); 8, 9, 12, Rammelsberg (ib., cxiii. 599); 10, 11, Wislicenus (J. pr. Ch., xciii. 260); 13, 14, Jacobson (Pogg., lxviii. 414); 15, Rammelsberg (l. c.); 16, Vauquelin (J. d. M., viii. 354); 17, 18, Jacobson (l. c.); 19, 20, Rammelsberg (l. c.); 21, 22, Jacobson (l. c.); 23–26, Rammelsberg (l. c.); 27, Genth (Am. J. Sci., II. xxxiii. 198); 28, Paykull (Œfv. Ak. H. Stockh., 1866):

In No. 2, G.=3·737—3·744; 4–7, G.=3·797 in pieces, 3·744 in powder; 12, G.=3·772; 13, 14, G.=3·66—3·73; 17, 18, G.=3·528; 20, G.=3·265; 21, 22, G.=3·549, 3·588; 23, G.=3·66; 24, G.=3·764; 25, G.=3·622; 26, G.=3·413; 27, zinc-staurolite, G.=3·792.

Lechartier obtained (Bull. Soc. Ch., II. iii. 375) the following results after purification :

	1, 2. St. Gothard.		3, 4. Brittany.		5. Quimper.	6. Bolivia.
Silica	28·21	28·48	28·16	28·98	29·15	29·07
Ign.	1·50	1·50	1·55	1·43	1·49	1·30
Sp. Gr.	3·75	3·74	3·75	3·70	3·76	

Before purification the silica obtained by him was for 2, 36·30; 3, 46·21—54·15; 4, 49·39; 5, 41·36 p. c. Nos. 3, 4, 5, 6 were large opaque crystals. He observes that all staurolite contains titanic acid, and that some magnesia is present.

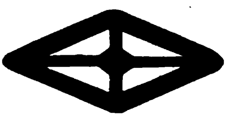
Pyr., etc.—B.B. infusible, excepting the manganesian variety (anal. 28), which fuses easily to a black magnetic glass. With the fluxes gives reactions for iron, and sometimes for manganese. Imperfectly decomposed by sulphuric acid.

Obs.—Usually found in mica schist, argillaceous schist, and gneiss; often associated with garnet, cyanite, and tourmaline.

Occurs with cyanite in *paragonite* schist, at Mt. Campione, Switzerland, in polished, brown, translucent crystals; at the Greiner mountain, Tyrol, in simple crystals associated with cyanite, and sometimes appearing as a continuation of its crystals, parallel with them; near Lake Como; in the Tyrol; at Goldenstein in Moravia, brown and translucent; in large twin crystals in Brittany; at Tornduff and near Killiney in Ireland; at Oporto, St. Jago de Compostella, and at other localities mentioned above.

Abundant throughout the mica slate of New England. In *Maine*, at Windham, near the bridge, the mica slate is filled with large crystals; also at Mt. Abraham, Hartwell, and Winthrop. In *N. Hamp.*, brown and large cryst. at Franconia; at Lisbon, abundant in mica slate; on the shores of Mink Pond, loose in the soil; at Grantham, 2 m. from Meriden, of a gray color. In *Vermont*, at Cabot. In *Mass.*, at Chesterfield, in fine crystals. In *Conn.*, at Bolton, Vernon, Litchfield, Stafford, and Tolland. In *New York*, small crystals at the Foss ore bed in Dover, Duchess Co.; also three and a half miles from New York city, on the Hudson. In *Penn.*, reddish-brown cryst. abundant on the Wissahiccon, 8 m. from Philadelphia. In *Georgia*, at the lead mine, Canton, in quartzose mica schist, the gangue of the lead ore.

379



Dr. O. T. Jackson has described a variety of staurolite in tesselated crystals like chiastolite, from Charlestown, N. H., as represented in the accompanying figure. He states that the staurolite macles pass by insensible shades into andalusite macles, where the mica slate passes into argillaceous slate.

Named from σταυρός, *a cross*. Haüy's change of *staurolite* to *staurotide* was neither necessary nor reasonable.

Alt.—Occurs altered to steatite.

334. SCHORLOMITE. *Shepard*, Am. J. Sci., II. ii. 251, 1846. Ferrotitanite *Whitney*, J. Nat Hist., Boston, vi. 46, 1849. ? Iwaarit *Kutorga*, 1851, *N. Nord.*, Vers. Finl. Min. 1852.

Massive, without cleavage.

H.=7–7·5. G.=3·862, Shepard; 3·807, Whitney; 3·783, in coarse powder, Rammelsberg; 3·745, fr. Kaiserstuhl, Claus. Color black, sometimes tarnished blue, and with pavonine tints; streak grayish-black. Lustre vitreous. Fracture conchoidal.

Comp.—O. ratio for $\dot{R}+\bar{\bar{R}}+\ddot{R}$ (bases), and silica=2 : 1 nearly, and for $\dot{R}$, $\ddot{R}$, $\bar{\bar{R}}$=4 : 4 : 3; whence $(\tfrac{1}{3}\dot{C}a^{3}+\tfrac{1}{3}\bar{\bar{F}}e+\tfrac{1}{3}\ddot{T}i^{\frac{3}{2}})^{4}\,\ddot{S}i^{3}$, and approaching closely the Coromandel tscheffkinite, but containing no cerium, and sesquioxyd of iron in place of alumina. Whitney deduced $\dot{C}a^3\,\dddot{S}i + \overline{F}e\,\dddot{S}i + \dot{C}a\,\ddot{T}i^2$=Silica 24·9, oxyd of iron, 21·9, lime 30·7, titanic acid 22·5=100. In Rammelsberg's second analysis, the silica was determined only by the loss, and in two of the other analyses there was titanic acid remaining with the silica.

Analyses: 1, 2, Whitney (l. c.); 3, 4, Rammelsberg (Pogg., lxxvii. lxxxv., and Min. Ch., 886, former analysis revised); 5, Crossley (This Min., 3d edit., 692); 6, Claus (Ann. Ch. Pharm., cxxix. 213):

6. Kaiserstuhl	29·55	21·18	18·08	1·22	25·13, $\dot{K}$, $\dot{N}a$ 4·22=99·38 Claus.

[a] With some titanic acid.

The mineral was first correctly described and analyzed by Whitney. Shepard made it a hydrous silicate of sesquioxyd of iron, yttria, and perhaps thoria.

Pyr., etc.—B.B. fuses quietly at 3 to a black glass. Reactions for iron with the fluxes. Fused with salt of phosphorus on charcoal, with tin, in the inner flame, gives a violet bead. Gelatinizes with muriatic acid, the solution becoming violet when boiled with metallic tin.

Obs.—In small masses with elæolite and brookite in the Ozark Mts., Magnet Cove, Arkansas. The dodecahedral crystals reported by Shepard are black garnets, which occur with it. Found also in the Kaiserstuhl, in the vicinity of Oberschaffhausen, in phonolite.

Named from a resemblance to schorl (black tourmaline).

IVAARITE. As described by Nordenskiöld (Beskr. Finl. Min., 1855, 101), it has the characters of schorlomite, and like it is found with elæolite. It occurs, he states, both massive and in garnet-like crystals, is lustrous black and opaque, with the lustre adamantine; has H.=6·5, and G.=3·67—3·69. The mineral is stated to consist of 6 $\dddot{S}i$, 3 $\ddot{T}i$, 2 $\overline{F}e$, 6 $\dot{C}a$, which corresponds to the O. ratio for bases and silica 3 : 2, instead of 2 : 1, the schorlomite ratio. B.B. fuses to a black glass. From Ivaara, Finland.

335. SAPPHIRINE. Sapphirin (fr. Greenland) *Giesecke*, Stromeyer's Unters., i. 391. Sapphirine. Sapphirin pt. [rest blue Spinel] *Hausm.*, Handb., 427, 1847.

Orthorhombic? In disseminated grains, or aggregations of grains.

H.=7—8. G.=3·42—3·48; 3·473, Damour. Lustre vitreous. Color pale blue or green. Translucent. Optically biaxial; and dichroic.

Comp.—O. ratio for $\dot{R}$, $\overline{R}$, $\dddot{S}i$=1 : 4 : 1; for bases and silica=5 : 1; constituents, $3\,\dot{M}g + 4\,\overline{A}l + 1\frac{1}{2}\,\dddot{S}i$=Silica 14·5, alumina 66·2, magnesia 19·3=100. The biaxial polarization shows that it is not impure corundum or spinel. Perhaps $(\frac{1}{2}\dot{M}g^3 + \frac{1}{2}\overline{A}l)^4\,\dddot{S}i^3 + 6\,\overline{A}l$, or a staurolite with corundum as an accessory. Possibly a 5 : 1 subsilicate. Analyses: 1 Stromeyer (Unters., i. 391); 2, 3, Damour (Bull. G. Soc., II. vi. 317, 1849):

	$\dddot{S}i$	$\overline{A}l$	$\dot{M}g$	$\dot{C}a$	$\dot{F}e$
1.	14·51	63·11	16·85	0·38	3·92, $\dot{M}n$ 0·53, ign. 0·49=99·78 Stromeyer
2.	14·88	63·31	19·06	——	2·09=99·34 Damour.
3.	14·84	63·20	19·50	——	1·90=99·44 Damour.

Pyr., etc.—B.B. alone and with borax infusible, unaltered.

Obs.—Associated with mica and anthophyllite at Fiskenaes in Greenland.

The name alludes to the sapphire color.

APPENDIX TO ANHYDROUS SILICATES.

336. EULYTITE. Arsenik-Wismuth *Wern.*, *Breith.*, Letzt. Min. Syst., 23, 62, Hoffm. Min., IV a, 65, 1817. Wismutblende, Eulytin, *Breith.*, Pogg., ix. 275, 1827; Handb., 303. Wismutisches Blende-Erz *Breith.*, Uib., 66, 1830, Char., 239, 1832. Kieselwismuth *Kersten*, Pogg., xxvii. 81, 1833. Silicate of Bismuth.

Isometric: tetrahedral. Usually in minute crystals, and edges often rounded, figs. 34, 35. Observed planes: 1, *O*, 2-2. Cleavage: dodecahedral, very imperfect. Twins: plane of composition parallel to a dodecahedral face. Crystals often in groups. Sometimes globular, and columnar, lamellar, or granular.

H.=4·5. G.=5·912—6·006. Lustre resinous or adamantine. Color dark hair-brown, yellowish-gray, grayish-white, and straw-yellow. Streak yellowish-gray or uncolored. Subtransparent—opaque. Fracture uneven. Rather brittle.

Comp.—Probably $\dddot{\overline{\mathrm{Bi}}}^4 \dddot{\mathrm{Si}}^3$, with some phosphate and fluorid of iron, Frankenheim. Analysis by Kersten (Pogg., xxvii. 81):

$\dddot{\mathrm{Si}}$ 22·2? $\dddot{\overline{\mathrm{Bi}}}$ 69·38 $\overline{\mathrm{P}}$ 3·31 $\dddot{\overline{\mathrm{Fe}}}$ 2·40 $\overline{\mathrm{Mn}}$ 0·30 HF, $\dot{\mathrm{H}}$, and loss 2·38=100.

Pyr., etc.—In a matrass decrepitates and affords a trace of water. B.B. fuses to a dark-yellow mass, and gives out inodorous fumes. Fuses and froths on charcoal, staining it yellowish-brown, sometimes with a tinge of green. Fuses readily with soda to a button, at first greenish-yellow and then reddish-yellow, and finally affords metallic bismuth. With salt of phosphorus it fuses to a yellow globule, with a silica skeleton, which becomes colorless on cooling.

Obs.—Found with native bismuth near Schneeberg, Saxony, in quartz, and at Bräunsdorf, near Freiberg.

Named from εὔλυτος, *easily dissolved*, or *fusible*.

337. ATELESTITE. *Breith.*, Char., 306, 1832.

Occurs in small monoclinic crystals, at Schneeberg, with eulytite; they have a sulphur-yellow color, adamantine lustre, H. about 5, and are transparent to translucent. Descloizeaux observes that some of the crystals, having the form of a rhombic octahedron, polarize light strongly.

Contains bismuth, but exact composition not ascertained.

338. HYPOCHLORITE. Sogenannter Grüneisenerde von Schneeberg, Hypochlorit, *Schüler*, Schw J., lxvi. 41, 1832, Dissert. de Ferro ochr., etc., *Jena*, 1832.

Minute crystalline; also earthy. H.=6. G.=2·9—3·04. Lustre vitreous, feeble. Color green. Streak light green. Brittle; fracture even to flat conchoidal.

Comp.—Analysis by Schüler (l. c.):

$\dddot{\mathrm{Si}}$ 50·24 $\dddot{\overline{\mathrm{Al}}}$ 14·65 $\dddot{\overline{\mathrm{Bi}}}$ 13·03 $\dot{\mathrm{Fe}}$ 10·54 $\overline{\mathrm{P}}$ 9·62 Mn *tr.*

Perhaps a mixture of a silicate of bismuth and iron, and a phosphate of alumina.

B.B. grows dark, but infusible; a yellow deposit on the coal. Insoluble in acids.

In minute crystals and grains, or massive and earthy, with native bismuth and cobalt ores, at Schneeberg, Johanngeorgenstadt, and Bräunsdorf, in Saxony. Also reported from Ullersreuth, Voigtland, in a bed of limonite.

Named from ὑπόχλωρος, on account of its green chlorite-like color.

338A. ISOPYRE. *Turner*, Ed. New Phil. J., iii. 263, 1827.

In compact masses, with cleavage.

H.=6—6·5. G.=2·9—3. Lustre vitreous. Streak light greenish-gray. Color grayish or velvet-black, occasionally spotted red, like heliotrope. Opaque—subtranslucent. Fracture flat conchoidal. Brittle. Acts slightly on the magnetic needle.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\overline{\mathrm{R}}}$, $\dddot{\mathrm{Si}}$, 1 : 3 : 6, as in labradorite. Analysis by Turner (l. c.):

$\dddot{\mathrm{Si}}$ 47·09 $\dddot{\overline{\mathrm{Al}}}$ 13·91 $\dddot{\overline{\mathrm{Fe}}}$ 20·07 $\dot{\mathrm{Ca}}$ 15·43 $\dot{\mathrm{Cu}}$ 1·94=98·44.

Part of the iron is supposed to be protoxyd, judging from the color of the mineral.

B.B. fuses easily to a magnetic bead, and colors the flame green. A silica skeleton with salt of phosphorus. With the acids decomposed with difficulty and imperfectly.

From St. Just, near Penzance, in a quartzose granite with tourmaline and tin ore, in pieces two inches in diameter. Also in breccia on the Calton Hill, Edinburgh, with limonite.

B. HYDROUS SILICATES.

Arrangement of the Species.

I. THE GENERAL SECTION OF HYDROUS SILICATES. Includes all Hydrous Silicates, excepting the Zeolites and the Margarophyllites.

1. Bisilicates.
2. Unisilicates.
3. Subsilicates.

II. ZEOLITE SECTION. Feldspar-like in constituents and oxygen ratio; the bases being alumina, and the alkalies and alkaline earths ($\dot{\mathrm{K}}$, $\dot{\mathrm{N}}\mathrm{a}$, $\dot{\mathrm{C}}\mathrm{a}$, $\dot{\mathrm{B}}\mathrm{a}$, $\dot{\mathrm{S}}\mathrm{r}$), to the almost total exclusion of magnesia and iron; and the oxygen ratio between the protoxyd and sesquioxyd bases being 1 : 3.

III. MARGAROPHYLLITE SECTION. Micaceous or thin foliated when crystallized; and plane angle of base of prism 120°.

On account of the uncertainties with respect to the relations of the water in hydrous silicates, the basis for a true classification of them is to a large extent wanting. From the dominance among anhydrous silicates of the grand subdivisions of Bisilicates, Unisilicates, and Subsilicates, the same groups might be reasonably looked for among the hydrous. But the formulas of very many of the species may be written according to either of these types, by making more, or less, or none, of the water basic; and consequently all attempts to define the limits of the groups must be at present unsatisfactory. Crystallographic and other relations to anhydrous species give help, but not always sure guidance.

The following examples elucidate some of the reasons for referring species to the section of Bisilicates rather than that of Unisilicates, or the reverse:

Laumontite (No. 342, beyond) has a close approximation in crystalline form to pyroxene, and this suggests a relation to the Bisilicates; moreover, its formula is wholly pyroxene-like, if the water is *not* basic. It is to be noted that part of the water escapes on heating to 100° C There is the same relation in form between *pectolite* and pyroxene, as long since shown by Frankenheim; and the same formula also, if the water, here a more stable constituent, is basic. *Okenite* is very near hornblende, or another anhydrous bisilicate, in its crystallization; and it is also like it in formula, if *half* the water is basic. In each of these cases crystallography appears to show whether any of the water, and how much, is basic. Again, *dioptase* has the angles nearly, and the bisilicate ratio, of beryl, if the water be *not* basic.

Prehnite has an affinity in its crystallization to chrysolite; and, if the water is *all* basic, the oxygen ratio for the bases and silica is 1 : 1, or that of a Unisilicate, as in chrysolite. Calamine is approximately isomorphous with prehnite, and, moreover, both are pyroelectric; and the oxygen ratio is 1 : 1, if the water is *not* basic. *Fahlunite*, a result of the alteration of iolite, is equivalent to iolite *plus* water. Iolite is a $\frac{4}{5}$ silicate, there being a deficiency of base for a true unisilicate; but the added water just fills up the deficiency, so that, if the water is basic, the species is strictly a Unisilicate, the O. ratio for $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, $\dddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$ being 1 : 3 : 5 : 1, or for the bases $\dot{\mathrm{R}}+\dddot{\mathrm{R}}+\dot{\mathrm{H}}$ and silica, 5 : 5=1 : 1. There seems to be no reason for questioning this basic relation of the water; it is probable that the deficiency of base may lead to the easy absorption of water so characteristic of iolite. In other alterations of iolite still more water is taken up, so that the O. ratio is 1 : 3 : 5 : 2; the compound is apparently the same, but with twice the proportion of water, only one-half of it in this case being basic. The same remarks are applicable to margarodite and other hydrous micas in their relations to muscovite and the anhydrous micas.

Apophyllite crystallizes in tetragonal forms—forms that are common among anhydrous Unisilicates, and are unknown among Bisilicates. The species is therefore arranged beyond as a Unisilicate, but as a representative of the Scapolite group of anhydrous silicates. *Tritomite* and *Thorite* are *isometric* species, and related to helvite and garnet; and they are Unisilicates, like garnet, if the water be *not* basic.

From these examples it is apparent that the facts give only probable conclusions. It is to be hoped that chemistry will soon furnish principles that are encumbered with less of doubt.

The group of *Zeolites* includes species that are feldspar-like in having among them the oxygen ratios for the protoxyds, alumina, and silica 1 : 3 : 4, 1 : 3 : 6, 1 : 3 : 8, 1 : 3 : 9, 1 : 3 : 12, with the only difference that water is present in addition. They are therefore sometimes spoken of as representatives among hydrous silicates of the anhydrous feldspars. But this inference, though apparently sustained by the oxygen ratios, is far from right. It assumes that the water is not basic. If it be basic, then the species may be ordinary Bisilicates or Unisilicates, quite remote from the feldspars. Looking to the crystallization, it is found that there is, in fact, nothing whatever to sustain the relation to the feldspars. The species of the Feldspar group are almost identical in angles and physical characters; while the zeolites are exceedingly diverse in both respects, and none have the feldspar form or angles. Nearly all the systems of crystallization are represented among them, and with a very wide range in angles. The feldspars have the prismatic angle near 120°; while the zeolites that approach the feldspars most nearly—that is, the *Stilbite* group, in which the oxygen ratio is 1 : 3 : 12, and the crystallization is in part oblique—have the prismatic angle near 90° in one species, and from 130° to 136° in others. The hexagonal species, chabazite, levynite, and gmelinite, usually made a subgroup among the zeolites, have widely different rhombohedral angles.

While, then, there is seeming unity in the group of zeolites, there is actually the widest diversity; and, when fully understood, they will probably have their places among the Unisilicates and Bisilicates of the first section. Analcite, which is included among the zeolites, is related in form to the feldspars, and in both form and formula (the water being excluded) to the anhydrous silicate, leucite.

The *Margarophyllites* appear to constitute a strictly natural group, although under a very various chemical constitution. They are foliated in structure like the micas, and, like them, have the plane angle of the base of the prism 120°, the crystallization being either hexagonal or prismatic, with the angles of base 120° and 60°. They include talc and pyrophyllite, margarodite and other hydrous micas, chlorite, margarite, etc.; with also kaolinite and serpentine, which have the same crystallization; and to these are added some species not yet known in the crystallized state, which appear to be chemically allied to the margarophyllites. The true margarophyllites are below 5 in hardness; greasy to the feel, at least when finely powdered; and not sparry in appearance when massive, unless through pseudomorphism, in which case this sparry character is that of the original mineral altered to make them.

I. GENERAL SECTION OF HYDROUS SILICATES.

ARRANGEMENT OF THE SPECIES.

The oxygen ratios of the species are given after the tables of formulas; the 1st column, the O. ratio for $\dot{\mathrm{R}}$, $\not{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$; 2d column for $\dot{\mathrm{R}}+\not{\mathrm{R}}$ (or bases), $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$. After the $\dot{\mathrm{H}}$ in the latter column, a fraction is added, giving the proportion of the water that is required to be added to the bases to make the ratio that of the formula. In *pectolite*, for example, all the water is to be added to the bases; this making the ratio of bases to silica 5 + 1 : 12 = 1 : 2.

I. BISILICATES.

1. PECTOLITE OR PYROXENOID GROUP. Monoclinic, and isomorphous with the Amphibole group (p. 207).

339. PECTOLITE	$(\frac{5}{6}(\dot{\mathrm{Ca}}, \dot{\mathrm{Na}})+\frac{1}{6}\dot{\mathrm{H}})\ddot{\mathrm{Si}}$	$\mathrm{Si}\,\Theta\|\Theta_2\|(\frac{1}{6}\mathrm{H}_2+\frac{5}{6}(\mathrm{Na}_2,\Theta\mathrm{a}))$
340. XONALTITE	$\mathrm{Ca}\ddot{\mathrm{Si}}+\frac{1}{4}\dot{\mathrm{H}}$	$\mathrm{Si}\,\Theta\|\Theta_2\|\Theta\mathrm{a}+\frac{1}{4}\,\mathrm{aq}$

341. **Okenite**	$(\tfrac12\dot{\text{C}}\text{a}+\tfrac12\dot{\text{H}})\ddot{\text{S}}\text{i}+\tfrac12\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac12\text{H}_2+\tfrac12\text{Ɵa})+\tfrac12\text{aq}$
342. **Gyrolite**	$(\tfrac23\dot{\text{C}}\text{a}+\tfrac13\dot{\text{H}})\ddot{\text{S}}\text{i}+\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac13\text{H}_2+\tfrac23\text{Ɵa})+\text{aq}$
343. **Laumontite**	$(\tfrac14\dot{\text{C}}\text{a}^3+\tfrac34\dddot{\text{A}}\text{l})\ddot{\text{S}}\text{i}^3+3\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac14\text{Ɵa}+\tfrac34\beta\text{Ⱥl})+\text{aq}$
343A. **Leonhardite**		

II DIOPTASE (OR BERYLLOID) GROUP. Hexagonal.

344. **Catapleiite**	$(\tfrac13(\dot{\text{N}}\text{a},\dot{\text{C}}\text{a})^3+\tfrac23\ddot{\text{Z}}\text{r})\ddot{\text{S}}\text{i}^3+1\tfrac13\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac13(\text{Na}_2,\text{Ɵa})+\tfrac23\gamma\ddot{\text{Z}}\text{r})+\text{aq}$
345. **Dioptase**	$\dot{\text{C}}\text{u}\,\ddot{\text{S}}\text{i}+\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|\,\text{Ɵu}$
346. **Chrysocolla**	$\dot{\text{C}}\text{u}\,\ddot{\text{S}}\text{i}+2\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|\text{Ɵu}+2\,\text{aq}$
347. **Alipite**	$(\tfrac23(\dot{\text{N}}\text{i},\dot{\text{M}}\text{g})+\tfrac13\dot{\text{H}})\ddot{\text{S}}\text{i}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac13\text{H}_2+\tfrac23(\text{Ꞥi},\text{Ɱg}))$
348. **Conarite**		

III. PICROSMINE GROUP.

349. **Picrosmine**	$\dot{\text{M}}\text{g}\,\ddot{\text{S}}\text{i}+\tfrac12\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|\text{Ɱg}+\tfrac12\text{aq}$
350. **Spadaite**	$(\tfrac56\dot{\text{M}}\text{g}+\tfrac16\dot{\text{H}})\ddot{\text{S}}\text{i}+\tfrac13\dot{\text{H}}$	$\text{Si}\,\Theta\|\Theta_2\|(\tfrac16\text{H}_2+\tfrac56\text{Ɱg})+\tfrac13\text{aq}$

II. UNISILICATES.

I. CALAMINE (OR CHRYSOLITHOID) GROUP. Orthorhombic. Approximately isomorphous with chrysolite.

361. **Calamine**	$\text{Ƶn}^2\ddot{\text{S}}\text{i}+\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\text{Zn}_2+\text{aq}$
362. **Villarsite**	$(\dot{\text{M}}\text{g},\dot{\text{F}}\text{e})^2\ddot{\text{S}}\text{i}+\tfrac12\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\text{Ɱg},\text{Fe})_2+\tfrac12\text{aq}$
363. **Prehnite**	$(\tfrac16\dot{\text{H}}^3+\tfrac36\dot{\text{C}}\text{a}^3+\tfrac26\dddot{\text{A}}\text{l})^2\ddot{\text{S}}\text{i}^3$	$\text{Si}\|\Theta_4\|(\tfrac16\text{H}_2+\tfrac36\text{Ɵa}+\tfrac26\beta\text{Ⱥl})_2$
364. **Chlorastrolite**	$(\tfrac13(\dot{\text{C}}\text{a},\dot{\text{N}}\text{a})^3+\tfrac23(\dddot{\text{A}}\text{l},\text{Ꞙe}))^2\ddot{\text{S}}\text{i}^3+2\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\tfrac13(\text{Na}_2,\text{Ɵa})+\tfrac23\beta(\text{Ⱥl},\text{Ꞙe}))_2+\tfrac23\text{aq}$

II. THORITE (OR HELVITOID) GROUP. Isometric.

365. **Tritomite**	$\ddot{\text{S}}\text{i}$, $\dot{\text{C}}\text{e}$, $\dot{\text{L}}\text{a}$, $\dot{\text{D}}\text{i}$, $\dot{\text{H}}$, etc.	
366. **Thorite**	$\ddot{\text{T}}\text{h}\,\ddot{\text{S}}\text{i}+1\tfrac12\dot{\text{H}}$	$\text{Si}\|\Theta_4\|\ \text{Ꝥh}_2+1\tfrac12\text{aq}$
367. **Cerite**	$(\dot{\text{C}}\text{e},\dot{\text{L}}\text{a},\dot{\text{D}}\text{i})^2\ddot{\text{S}}\text{i}+\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\text{Ɵe},\text{Ⱡa},\text{Đi})_2+\text{aq}$
368. **Erdmannite**		

III. PYROSMALITE GROUP. Hexagonal.

369. **Pyrosmalite**	$(\tfrac14\dot{\text{H}}+\tfrac34(\dot{\text{F}}\text{e},\dot{\text{M}}\text{n},\text{FeCl}))^2\ddot{\text{S}}\text{i}$	$\text{Si}\|(\Theta,\text{Cl}_2)_4\|(\tfrac14\text{H}_2+\tfrac34(\text{Fe},\text{Mn}))_2$

IV. APOPHYLLITE GROUP. Tetragonal, with perfect basal cleavage.

870. APOPHYLLITE $(\dot{H}, \dot{C}a, \dot{K})^2 \ddot{Si} + \dot{H} \ddot{Si}$ $Si|\Theta_4|(\frac{1}{2}H_2+\frac{1}{2}(K_2,\Theta a))_2 + H_2Si\Theta$

V. GISMONDITE GROUP. Tetragonal and hemihedral, or orthorhombic; lateral cleavage 'n short and small crystals.

871. EDINGTONITE ?$(\frac{3}{7}\dot{H}+\frac{4}{7}\dot{B}a)^2 \ddot{Si} + \frac{4}{7}\dot{H}$ $Si|\Theta_4|(\frac{3}{7}H_2+\frac{4}{7}Ba)_2+\frac{4}{7}aq$

872. GISMONDITE $(\frac{2}{3}\dot{C}a+\frac{1}{3}\dot{K})+\dddot{\bar{A}}l, 2\frac{1}{4}\ddot{Si}, 4\frac{1}{2}\dot{H}$

VI. CARPHOLITE GROUP.

873. CARPHOLITE $(\dddot{\bar{A}}l, \dddot{\bar{M}}n, \dddot{\bar{F}}e)^2 \ddot{Si}^3 + 3\dot{H}$ $Si|\Theta_4|\beta(Al, Mn, Fe)_2 + aq$

III. SUBSILICATES.

874. ALLOPHANE $\dddot{\bar{A}}l \ddot{Si} + 6\dot{H}$ (or $5\dot{H}$) $\beta Al_2\Theta|\Theta_4|Si + n\,aq$

875. COLLYRITE $\dddot{\bar{A}}l^2 \ddot{Si} + 9\dot{H}$ =1 Allophane+1 Gibbsite

876. SCHRÖTTERITE $\dddot{\bar{A}}l^8 \ddot{Si}^3 + 30\dot{H}$ =3 Allophane+5 Gibbsite

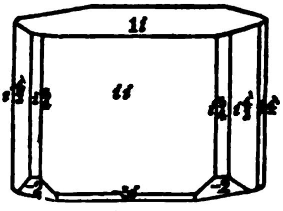
The O. ratio for $\dddot{\bar{R}}$, $\ddot{Si}$, $\dot{H}$ in Allophane is 3 : 2 : 6; in Collyrite 6 : 2 : 9; in Schrötterite 4 : 1 : 5. The species Euclase (p. 379) and Datolite (p. 380) are true hydrous Subsilicates. The reason for placing them with the anhydrous species is stated on page 204.

I. BISILICATES.

339. PECTOLITE. Pektolith *v. Kobell*, Kastner's Arch., xiii. 385, 1828, xiv. 341. Photolith *Breith.*, Char., 181, 1832. Wollastonite, Stellite, *Thomson*, Min., i. 130, 313. Ratholite *some collectors.* Osmelith *Breith.*, Pogg., ix. 183, 1827.

Monoclinic, isomorphous with wollastonite. Observed planes: *O*; vertical, *i-i*, *i*-$\frac{5}{4}$, *i*-$\frac{3}{2}$, *i*-4; hemidomes, 1-*i*, –5-*i*; hemioctahedral, –2. Angles measured by Greg:

380



Ratho

i-i ∧ 1-*i* = 95° 23′
i-i, back, ∧ 1-*i* = 84 37
i-i ∧ *i*-$\frac{5}{4}$ = 139 30
i-i ∧ *i*-$\frac{3}{2}$ = 125° 55′
i-i ∧ *i*-4 = 102 30
i-i ∧ –2 = 132 54

Cleavage: *i-i* (orthod.) perfect. Twins: composition-face *i-i*. In close aggregations of acicular crystals. Fibrous massive, radiated to stellate. H.=5. G.=2·68–2·78. Lustre of the surface of fracture silky or subvitreous. Color whitish or grayish. Subtranslucent to opaque. Tough. Fo

Bergen mineral optic-axial plane parallel to orthodiagonal, and very nearly normal to *i-i*; acute bisectrix positive, parallel to orthodiagonal, and obtuse bisectrix nearly normal to cleavage-plane or *i-i*; axial angle in oil, through cleavage plates, 143°—145°; Descl.

Var.—Almost always columnar or fibrous, and divergent, the fibres often 2 or 3 inches long, and sometimes, as in Ayrshire, Scotland, a yard. Resembles in aspect fibrous varieties of natrolite, okenite, thomsonite, tremolite, and wollastonite. *Osmelite*, from Niederkirchen, near Wolfstein, Bavaria, is columnar and radiated; G.=2·799—2·833, Breith.; color grayish-white, yellowish, gray.

Comp.—O. ratio for $\dot{R}$, $\dddot{S}i$, $\dot{H}$=5 : 12 : 1; whence, if the water is basic, $(\frac{4}{6}\dot{C}a+\frac{1}{6}\dot{N}a+\frac{1}{6}\dot{H})\dddot{S}$ =Silica 54·2, lime 33·8, soda 9·3, water 2·7=100. Analyses: 1. v. Kobell (Kastner's Arch. Nat., xiii. 385); 2, 3, J. D. Whitney (Jour. Soc. N. H. Bost., 1849, p. 36, and Am. J. Sci., II. vii. 434); 4, J. S. Kendall (ib.); 5, G. J. ᵃ With some Mn O. ᵇ The iron protoxyd. ᶜ With some K O.

Berzelius obtained a fluorine reaction with the Monzoni mineral. The analysis by Adam (No. 17) makes the *osmelite* identical with pectolite. Riegel obtained a very different result (Jahrb. f. pr. Pharm., xiii. 1); but v. Kobell has confirmed Adam's result, and shown that Riegel must have had in hand another mineral.

Pyr., etc.—In the closed tube yields water. B.B. fuses at 2 to a white enamel. Gelatinizes with muriatic acid. Often gives out light when broken in the dark.

Obs.—Occurs mostly in trap and related rocks, in cavities or seams; occasionally in metamorphic rocks. Found in Scotland at Ratho Quarry, and Castle Rock, near Edinburgh; at Kilsyth, Costorphine Hill, Loch End, Girvan, and Knockdolian Hill, in Ayrshire; and at Talisker, etc., I. Skye. Also at Mt. Baldo and Mt. Monzoni in the Tyrol, where first obtained; at an iron mine in Wermland, associated with chlorite and calcite.

Occurs also at Bergen Hill, N. J., in large and beautiful radiations; compact at Isle Royale, L. Superior.

Descloizeaux obtained from Bergen crystals, *i-i* ∧ 1-*i*=95° 30′ and 84° 30′. Wollastonite gives *i-i* ∧ 1-*i*=95° 23′, *i-i* ∧ -5-*i*=159° 32′, *i-i* ∧ *i*-$\frac{4}{3}$=140° 5′, *i-i* ∧ -2=93° 52′.

340. XONALTITE. Xonaltit *Rammelsberg*, ZS. G., xviii. 33, 1866.

Massive. Very hard. G.=2·71, white; 2·718, gray. Color white to bluish-gray. Tough. Fracture splintery.

O. ratio for $\dot{\mathrm{Ca}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=4 : 8 : 1; whence 4 $\dot{\mathrm{Ca}}\,\ddot{\mathrm{Si}}+\dot{\mathrm{H}}$=Silica 49·80, lime 46·47, water 3·73=100. Analyses· 1, 2, Rammelsberg (l. c.):

2.	*Gray*	50·25	2·28		0·19	43·92	4·07=100·71 Rammelsberg.

Yields water. Infusible [?]. Decomposed by muriatic acid (Ramm.). Occurs at Tetela de Xonalta, Mexico, in concéntric layers, with apophyllite and bustamite.

341. OKENITE.

Okenit *v. Kobell*, Kastner's Arch., xiv. 333, 1828. Dysclasite *Connel*, Ed. Phil. J., xvi. 198, 1834. Bordite *Adam*, Dufr. Min., iv. 697, 1859.

Orthorhombic? $I \wedge I$=122° 19′, Breith. Composed of a congeries of minute acicular crystals; commonly fibrous; also compact.

H.=4·5—5. G.=2·28—2·37; 2·362 of dysclasite, Connel; 2·28 of okenite, v. Kobell. Lustre subpearly. Color white, with a shade of yellow or blue; often yellow by reflected light, and blue by transmitted. Frequently opalescent. Subtransparent—subtranslucent. Very tough.

Var.—*Bordite*, from Bordöe, one of the Faröe islands, is only a very fine fibrous milk-white okenite, firm in texture and very tough, and having H.=3·5, G.=2·33.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$≐1 : 4 : 2; whence, if half of the water is basic, 2 : 4 : 1; and the formula $(\frac{1}{2}\dot{\mathrm{H}}+\frac{1}{2}\dot{\mathrm{Ca}})\ddot{\mathrm{Si}}+\frac{1}{2}\dot{\mathrm{H}}$=Silica 56·6, lime 26·4, water 17·0=100. It has the prismatic angle nearly of amphibole, to which it is related in composition. Analyses: 1, 2, v. Kobell (l. c.); 3, Connel (l. c.); 4, Würth (Pogg., lv. 113); 5, v. Hauer (Jahrb. G. Reichs., 1854, 190); 6, Schmid (Pogg., cxxvi. 143); 7, Adam (l. c.):

		$\ddot{\mathrm{Si}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
1.	Greenland	55·64	26·59	17·00, $\bar{\dddot{\mathrm{Al}}}$ and $\bar{\dddot{\mathrm{Fe}}}$ 0·53, $\dot{\mathrm{K}}$ *tr.*=99·76 Kobell.

7.	*Bordite*	56·92	25·14	14·19, $\bar{\dddot{\mathrm{Al}}}$ 0·67, $\dot{\mathrm{Na}}$ 1·04=97·94 Adam.

Pyr., etc.—In a matrass yields water. B.B. alone becomes opaque and white, and fuses to a glass. Effervesces with soda, and fuses to a subtransparent glass, which is milk-white on cooling; with borax forms a transparent colorless glass. Gelatinizes readily in muriatic acid.

Obs.—Occurs in trap or related eruptive rocks. Found at the Faröe Islands; in Iceland; on the island of Disko, Greenland.

342. GYROLITE.

Gurolite *Anderson*, Phil. Mag., IV. i. 101, 1851. Gyrolite.

In concretions, lamellar-radiate in structure.

H.=3—4. Lustre vitreous to pearly. Color white. Translucent, becoming opaque.

Comp.—$(\frac{2}{3}\dot{\mathrm{Ca}}+\frac{1}{3}\dot{\mathrm{H}})\ddot{\mathrm{Si}}+\dot{\mathrm{H}}$. Analyses: 1, Anderson (l. c.); 2, How (Am. J. Sci., II. xxxii. 13):

		$\ddot{\mathrm{Si}}$	$\bar{\dddot{\mathrm{Al}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$

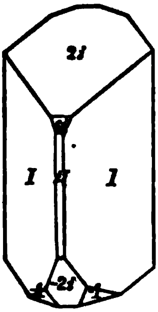
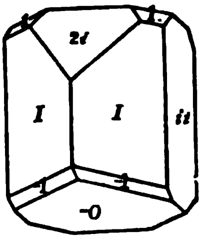
381



Mt. Catini.

382



Huelgoet.

Twins: composition-face *i*-*i*. Also columnar, radiating or divergent.

H.=3·5–4. G.=2·25–2·36. Lustre vitreous, inclining to pearly upon the faces of cleavage. Color white, passing into yellow or gray, sometimes red. Streak uncolored. Transparent—translucent; becoming opaque and usually pulverulent on exposure. Fracture scarcely observable, uneven. Not very brittle. Double refraction weak; optic-axial plane *i*-*ì*; divergence 52° 24′ for the red rays; bisectrix negative, making an angle of 20° to 25° with a normal to *i*-*i*; Descl.

Var.—Laumontite of Huelgoet has G.=2·29; of Sarnthal, Tyrol, 2·28 (Gericke); of Plauenscher Grund (Gericke) and Helsingfors (Arppe) 2·31; of the red, from I. Skye, 2·252 (J. W. Mallet). *Caporcianite* occurs in pearly monoclinic crystals, of a flesh-red color, having G.=2·47, and H.=3·5.

Comp.—O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{Si}$, $\dot{H}$=1 : 3 : 8 : 4; and for $\dot{R}+\dddot{\bar{R}}$, $\dddot{Si}$, $\dot{H}$=1 : 2 : 1; whence the formula $(\frac{1}{4}\dot{Ca}^3+\frac{3}{4}\dddot{\bar{Al}})\dddot{Si}^2+3\dot{H}$=Silica 50·9, alumina 21·9, lime 11·9, water 15·3=100. Both in formula and crystallization it is related to pyroxene.

Analyses: 1, 2, Dufrénoy (Ann. d. Mines, III. viii. 503); 3, Connel (Ed. N. Phil. J., 1829, 282); 4, 5, Babo and Delffs (Pogg., lix. 339); 6, Malaguti and Durocher (Ann. d. Mines, IV. ix. 325); 7, Sjögren (Pogg., lxxviii. 415); 8, Scott (Ed. N. Phil. J., 1852, liii. 284); 9, 10, Gericke (Ann. Ch. Pharm., xcix. 110); 11, Arppe (An. Finsk. Min., 22); 12, J. W. Mallett (Am. J. Sci., II. xxii. 179); 13, How (ib., xxvi. 30):

An impure Swiss laumontite has been analyzed by Fellenberg (Mitth. Berne, 54, 1865).

The Ædelforsite of Retzius, or the *Red Zeolite of Ædelfors*, is referred here by N. J. Berlin, who considers it impure from mixed silica (quartz), and related to the red zeolite of Upsala analyzed by him. It afforded Retzius $\ddot{\mathrm{Si}}$ 60·28, $\dddot{\bar{\mathrm{Al}}}$ 15·42, $\dot{\mathrm{Ca}}$ 8·18, $\dddot{\bar{\mathrm{Fe}}}$ 4·16, $\dot{\mathrm{Mg}}$ and $\dot{\mathrm{Mn}}$ 0·42, $\dot{\bar{\mathrm{H}}}$ 11·07=99·53. A similar mineral from Fahlun yielded Hisinger $\ddot{\mathrm{Si}}$ 60·00, $\dddot{\bar{\mathrm{Al}}}$ 15·6, $\dddot{\bar{\mathrm{Fe}}}$ 1·8, $\dot{\mathrm{Ca}}$ 8·0, $\dot{\bar{\mathrm{H}}}$ 11·6=97·0; while he obtained for the Ædelfors zeolite $\ddot{\mathrm{Si}}$ 53·76, $\dddot{\bar{\mathrm{Al}}}$ 18·47, $\dddot{\bar{\mathrm{Fe}}}$ 4·02, $\dot{\mathrm{Ca}}$ 10·90, $\dot{\bar{\mathrm{H}}}$ 11·23=98·38, which is near the composition of laumontite. Bischof has analyzed a pseudomorph of laumontite after orthoclase (see ORTHOCLASE).

Pyr., etc.—In a vacuum, Huelgoet laumontite crystals, according to Malaguti & Durocher, lose in weight 2·26 p. c., and, over sulphuric acid, 3·85 p. c.; and regain the same in water or moist air. Heated up to 100° C., they lose 3·17 p. c.; to 200°, 6·08 p. c.; to 300°, 7·28; and the remainder of the water only at a red heat. B.B. swells up and fuses at 2 7—3 to a white enamel. Gelatinizes with muriatic acid.

Obs.—Laumontite occurs in the cavities of trap or amygdaloid; also in porphyry and syenite, and occasionally in veins traversing clay slate with calcite. It was first observed in 1785, in the lead mines of Huelgoet in Brittany, by Gillet Laumont, after whom it is named.

Its principal localities are at the Faröe Islands; Disko in Greenland; in Bohemia, at Eule in clay slate; St. Gothard in Switzerland; the Fassathal, in large masses exhibiting a radiated structure; Sarnthal, near Botzen, Tyrol; Plauenscher Grund, near Dresden; Hartfield Moss in Renfrewshire, accompanying analcite; the amygdaloidal rocks in the Kilpatrick hills, near Glasgow; and in several trap rocks of the Hebrides, and the north of Ireland.

Peter's Point, Nova Scotia, affords fine specimens of this species. It is there associated with apophyllite, thomsonite, and other species of this family; also at Port George, N. S., in veins sometimes 3 in. thick, and at Margaretville, colored green by copper; also at Digby Neck and Long Point. Also found in good specimens at Phipsburg, Maine; also sparingly at Bradleysville, Litchfield Co., Conn., near a paper-mill, in narrow seams in gneiss; and at Southbury, Conn., a little east of the village, on the land of Mr. Stiles. Abundant in many places in the copper veins of Lake Superior in trap, and on I. Royale; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac. Found also at Bergen Hill, N. J., in greenstone, with datolite, apophyllite, etc.; sparingly at Phillipstown, N. Y., in feldspar with stilbite, and at Columbia bridge, near Philadelphia.

Alt.—Most varieties become opaque and crumble at the touch after exposure to the ordinary atmosphere, losing 1 to 2 p. c. of water. Specimens in cabinets can be best preserved from alteration by keeping them in moist air.

Schneiderite (l. c.) is laumontite from the serpentine of Monte Catini, Italy, which has undergone alteration through the action of magnesian solutions. It is described by Meneghini as laminate-radiate in structure, with H.=3. Fig. 381 represents a crystal from Mt. Catini (one received by Prof. G. J. Brush from Prof. Bechi); it gave the author the approximate angles $I \wedge I=$ ' 5°—86° 30′, *i-i* ∧ 2-*i*=126°, −2-*i* ∧ *i-i*=148° 15′, $I \wedge -1=135°$, −1 ∧ −1, front,=133°, 2-*i* ∧ 6-*i*= 44°. The planes had little lustre, and that strongly pearly. Bechi obtained in an analysis (l. c.):

$\ddot{\mathrm{Si}}$ 47·79 $\dddot{\bar{\mathrm{Al}}}$ 19·38 $\dot{\mathrm{Mg}}$ 11·03 $\dot{\mathrm{Ca}}$ 16·77 $\dot{\mathrm{Na}}$, $\dot{\mathrm{K}}$ 1·63 $\dot{\bar{\mathrm{H}}}$ 3·41=100.

It fuses B.B. with intumescence, and gelatinizes in cold acids. Occurs with sloanite in the gabbro rosso of Tuscany. Named after Sign. Schneider, director of the mine of Mount Catini

CAPORCIANITE *Savi* (Mem. cost fis. Toscana, ii. 53). Has been referred to laumontite. [illegible]s described by Meneghini as resembling heulandite and near it in its angles, affording (see f. [illegible], p. 444) 2-*i* ∧ −2-*i*=131°, 2-*i* ∧ I=150°, with cleavage parallel to *i-i* very easy, and also parallel to 2-*i*; easy parallel to −2-*i*; faces 2-*i* minutely striated; also in twins; also imperfectly radiated foliaceous. H.=2·5; G.=2·470; color flesh-red; lustre pearly.

COMP.—$\dot{\mathrm{Ca}}^3 \ddot{\mathrm{Si}}^2 + 3 \dddot{\bar{\mathrm{Al}}} \ddot{\mathrm{Si}}^3 + 9 \dot{\bar{\mathrm{H}}}$, Ramm., and near laumontite=Silica 53·0, alumina 22·7, lime 12·4, water 11·9=100. Analyses: 1, Anderson (Ed. Phil. J., 1842, 21); 2, Bechi (Am. J. Sci. II. xiv. 62):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\bar{\mathrm{H}}}$
1.	52·8	21·7	0·1	11·3	0·4	0·2	1·1	13·1=100·7 Anderson.
2.	52·02	22·83	—	9·68	1·11	0·25	1·11	13·17=100·17 Bechi.

B.B. fuses to a white enamel without intumescence. Dissolves easily in acids, and forms a jelly even in the cold. Occurs in geodes with calcite in the gabbro rosso of Monte de Caporciano at l'Impruneta, and other places in Tuscany. It is sometimes accompanied by native copper.

343A. LEONHARDITE *Blum* (Pogg., lix. 336, 1843). Near laumontite, and probably that species Monoclinic $I \wedge I = 83° 30'$, and $96° 30$; $O \wedge I = 114°$. Cleavage parallel with I very perfect, basal imperfect. Also columnar and granular.

H.=3–3·5. G.=2·25. Lustre of cleavage-face pearly, elsewhere vitreous. White, sometimes yellowish, seldom brownish. Subtranslucent. Usually whitens on exposure like laumontite.

Analyses: 1, Delffs (Pogg., lix. 336, 339); 2, Babo (ib.); 3, 4, G. O. Barnes (Am. J. Sci., II. xv. 440):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$
1. Schemnitz	56·128	22·980	9·251	11·641=100 Delffs.
2. "	55·00	24·36	10·50	12·30=102·16 Babo.
3. Copper Falls	55·96	21·04	10·49	11·93=99·42 Barnes.
4. " "	55·04	22·34	10·64	11·93=99·95 Barnes.

These results afford the following O. ratios for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$: (1) 1 : 4 : 11½ : 4½; (2) 1 : 4 : 10 : 3½; (3, 4) 1 : 3½ : 10 : 3½. Delffs' analysis was made after drying the mineral at 100° C.; dried at the ordinary temperature it gave 13·547–13·807 water, which corresponds to the above formula. B.B. exfoliates, froths, and easily melts to an enamel. Dissolves in acids.

From a trachytic rock at Schemnitz in Hungary; at Pfitsch in an earthy chlorite, and near Predazzo in the Fleims Valley, Tyrol, in a melaphyre. Also at Copper Falls, Lake Superior region, a variety which alters but little on exposure.

Lewinstein has analyzed two altered specimens from the copper mines of Lake Superior (ZS. Ch. u. Pharm. 1860, 11), one (A) containing 76 p. c. of the mineral, the other (B) 81·61 p. c., the rest impurity; A, of a brownish-red color, and B, greenish, afforded, impurity excluded:

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
A.	57·92	10·19	1·19	1·13	4·59	1·14	2·58	21·26=100.
B.	55·21	22·58	2·55	1·31	0·98	3·45	3·41	10·51=100.

A gives nearly the O. ratio 1 : 2 : 12 : 8; and B, 1 : 5 : 13 : 4·3.

344. CATAPLEIITE. Katapleiit *Weibye & Sjögren*, Pogg., lxxix. 299, 1850.

Hexagonal. In thin tabular hexagonal prisms, with the basal edges replaced by the planes 1, 2, 4; $O \wedge 1 = 142° 4'$, $O \wedge 2 = 122° 40'$, $O \wedge 4 = 107° 47'$. Cleavage: lateral (I) perfect; 2, distinct. Also massive.

H. near 6. G.=2·8. Lustre nearly dull, weak vitreous on surface of fracture. Color light yellowish-brown. Streak isabella-yellow. Opaque.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 2 : 6 : 2; for $\dot{\text{R}}+\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 2 : ⅔; whence the formula $(\frac{1}{3}\dot{\text{R}}^3+\frac{2}{3}\ddot{\text{Zr}})\ddot{\text{Si}}^2+1\frac{1}{3}\dot{\text{H}}$. Analyses by Sjögren (l. c.):

	$\ddot{\text{Si}}$	$\ddot{\text{Zr}}$	$\bar{\text{Al}}$	$\dot{\text{Na}}$	$\dot{\text{Ca}}$	$\bar{\text{Fe}}$	$\dot{\text{H}}$
1.	46·83	29·81	0·45	10·83	3·61	0·63	8·66=101·02.
2.	46·52	29·33	1·40	10·06	4·66	0·49	9·05=101·51.

Pyr., etc.—In the closed tube yields water. B.B. in the platinum forceps fuses at 3 to a white enamel; with borax a clear colorless glass. Easily soluble in muriatic acid without gelatinizing: the dilute acid solution colors turmeric paper orange-yellow (reaction for zirconia).

Obs.—From the island Lamöe near Brevig, Norway, along with zircon, leucophanite, mosandrite, and tritomite.

On the crystallization see H. Dauber, Pogg., xcii. 239.

345. DIOPTASE. Achirit *B. F. J. Hermann*, 1788, N. Act. Petrop., xiii. 339, 1802. Emeraudine *Delameth.*, T. T., ii. 230, 1797. Kupfer-Schmaragd *Wern.*, 1800, Ludwig, i. 53, 233, 1803 Dioptase *H.*, Tr., iii. 1801. Emerald-Copper *Jameson*. Smaragdo-Chalcit *Mohs*, Gundr., 1824.

Rhombohedral. $R \wedge R=126°\ 24'$; $O \wedge R=148°\ 38'$; $a=0\cdot5281$. Observed planes: rhombohedral, 1 (R), 2, -2; hemi-scalenohedral on three alternate edges, as in the figure, with also 2^3; also 1^3; prismatic, i-2, i-$\frac{3}{2}$, i-$\frac{4}{3}$, i-$\frac{8}{7}$, the last three hemihedral.

3.	36·47	50·10	11·40, $\bar{\ddot{\mathrm{F}}}\mathrm{e}$ 0·42, $\dot{\mathrm{C}}\mathrm{a}\,\ddot{\mathrm{C}}$ 0·35=98·74 Damour.
4.	38·93	49·51	11·27=99·71 Damour.

Pyr., etc.—Like chrysocolla, but gelatinizes with muriatic acid.

Obs.—Dioptase occurs disposed in well defined crystals and amorphous on quartz, occupying seams in a compact limestone west of the hill of Altyn-Tübeh in the Kirghese Steppes. Also reported as found in the Duchy of Nassau, between Oberlahnstein and Braubach.

Breithaupt found for the angle $R \wedge R$ 125° 55′; and Kokscharof, after careful measurement, adopts this value (Bull. Ac. St. Pet., ix. 240).

Named by Haüy *dioptase*, from διά, *through*, and ὀπτομαι, *to see*, because the cleavage directions were distinguishable on looking through the crystal.

Named *Achirite* after Achir Mahméd, a Bucharian merchant, living at the fortress of Semipalatna on the Irtish, who had procured it in the region where it occurred, and who furnished the specimens that were taken in 1785 by Mr. Bogdanof to St. Petersburg. Although first named by Hermann, his description was not given to the St. Petersburg Academy before 1800, and the volume containing it was not published until 1802, a year after the appearance of Haüy's work.

Cryptocrystalline; often opal-like or enamel-like in texture; earthy. Incrusting, or filling seams. Sometimes botryoidal.

H.=2—4. G.=2—2·238. Lustre vitreous, shining, earthy. Color mountain-green, bluish-green, passing into sky-blue and turquois-blue; brown to black when impure. Streak, when pure, white. Translucent—opaque. Fracture conchoidal. Rather sectile; translucent varieties brittle.

Comp.—Composition varies much through impurities, as with other amorphous substances, resulting from the alteration. As the silica has been derived from the decomposition of other silicates, it is natural that an excess should appear in many analyses.

True chrysocolla appears to correspond to the O. ratio for $\dot{C}u$, $\ddot{S}i$, $\dot{\bar{H}}$, 1 : 2 : 2=$\dot{C}u\,\ddot{S}i+2\,\dot{\bar{H}}$ =Silica 34·2, oxyd of copper 45·3, water 20·5=100, the water being double that of dioptase. But some analyses afford 1 : 2 : 3=$\dot{C}u\,\ddot{S}i+3\,\dot{\bar{H}}$ (anal. 13), and 1 : 2 : 4=$\dot{C}u\,\ddot{S}i+\dot{\bar{H}}$ (anal. 11).

Impure chrysocolla may contain, besides free silica, black oxyd of copper, oxyd of iron (or limonite), and oxyd of manganese; and consequently vary in color from bluish-green to brown and black, the last especially when oxyd of manganese or of copper is present. Other kinds are impure with carbonate or sulphate of copper; and others with oxyds of lead, antimony, arsenic, etc.

Analyses: 1, v. Kobell (Pogg., xviii. 254): 2-4 Berthier (Pogg., xxviii. 411); 5, Bowen (Am. J. Sci., viii. 18); 6, Beck (Am. J. Sci., xxxvi. 111); 7, Scheerer (Pogg., lxv. 289); 8, C. T. [a] Loss included. [b] With some Al^2O^3.

The mineral from Somerville, N. J., as described by Berthier (Ann. Ch. Phys., li. 395), is of three varieties: (1) a thin, green, transparent incrustration; (2) a bluish-green earthy mineral, very tender and light, becoming transparent, like hydrophane, in water; and (3) a pale greenish-blue massive material, hard enough to scratch glass, and to be polished for jewelry; and he observes that the chrysocolla is nearly pure in the first, but is mixed with opal-silica in much of the second kind, and with opal-silica and ordinary silica in the last. Berthier's analysis (No. 4 above) was made on a specimen of the second kind, and according to him probably contained 8 p. c. of opal-silica in a state of mixture. Berthier, allowing for 8 p. c. of free silica in this analysis, suggests that the composition may be $\dot{C}u\,\ddot{S}i+4\,\dot{\bar{H}}$, while Bowen's earlier analysis (5) gives $\dot{C}u\,\ddot{S}i+2\,\dot{\bar{H}}$. Berthier's mineral has been named (without sufficient reason) *Somervillite*, and the analysis has generally been taken as expressing directly his view of the composition. Berthier gives an analysis also of the hard chrysocolla of Somerville (*third* kind) to show that there is in these ores free silica. He obtained (l. c.) Silica 28·9, oxyd of copper 6·1, water 6·7, oxyd of iron 0·4, *silica soluble in the alkalies* 57·9=100.

The specimen for No. 13 had a fine turquois-blue color, and was from Tambillos near Coquimbo.

Demidoffite occurs at Tagilsk, Urals, in mammillated crusts of a sky-blue color, and afforded N. Nordenskiöld (l. c.) $\ddot{S}i$ 31·55, $\dddot{\bar{A}}l$ 0·53, $\dot{C}u$ 33·14, $\dot{M}g$ 3·15, $\dot{\bar{H}}$ 23·03, $\ddot{\bar{P}}$ [10·22]=100.

Hermann has given (l. c.) the name *Asperolite* to an amorphous mineral from Tagilsk, Russia. It occurs in reniform masses of the size of the fist, of a bluish-green color, conchoidal fracture, smooth and lustrous. Brittle. H.=2·5; G.=2·306. Analysis afforded him $\ddot{S}i$ 31·94, $\dot{C}u$ 40·81, $\dot{\bar{H}}$ 27·25=100. O. ratio for $\dot{R}$, $\ddot{S}i$, $\dot{\bar{H}}$=1 : 2 : 3. He considers it one of a series of silicates of copper, consisting of dioptase, chrysocolla, asperolite, and a mineral described by Nordenskiöld, containing respectively 1, 2, 3, and 4 eq. $\dot{\bar{H}}$. Named *asperolite* on account of its great brittleness

The following are analyses of other impure varieties; 1, Ullmann (Syst. tab. Uebers., 275); 2, Klaproth (Beitr., iv. 34); 3, Thomson (Min., i. 1836); 4, v. Kobell (J. pr. Ch., xxxix. 209); 5, Damour (Ann. d. M., III. xii.); 6, Rammelsberg (Min. Ch., 552); 7, Berthier (Ann. d. M., III. xix 698); 8, Domeyko (Min., 1860, 139); 9, F. Field (Phil. Mag., IV. xxii. 361); 10, 11, Domeyko (l. c.)

Nos. 1 to 3 contain some carbonate of copper; and 1 has been named *Dillenburgite*. Nos. 4 to 6 are *Kupferpechers* (or *Hepatinerz*), a brown variety containing much limonite as impurity; No. 7 contains 25 p. c. of sulphate of copper; Nos. 8, 9 contain oxyd of manganese, and are black in color; Nos. 10, 11 include black oxyd of copper. Nos. 7 to 11 are all from the vicinity of Coquimbo. The cupreous variety abounds especially at the Higuera mines; and 10 is from the Cortadero mine; 11 from the Brillador.

The chrysocolla of Rochlitz, in the Riesengebirge, afforded Herter & Porth (Jahrb. G. Reichs., x. 10) $\ddot{\text{S}}\text{i}$ 42·93—43·43, $\dot{\text{C}}\text{u}$ 16·11—29·37, $\dot{\text{P}}\text{b}$ 1·73—5·05, $\dot{\text{Z}}\text{n}$ 7·43—0·50, $\dot{\text{C}}\text{a}$ 2·00—1·54, $\dot{\text{M}}\text{g}$ 4·46—0·33, $\ddot{\bar{\text{A}}}\text{l}$ 5·56—9·85, $\ddot{\bar{\text{F}}}\text{e}$ 10·07—2·08, $\dot{\bar{\text{H}}}$ 9·23—8·61, and 32 p. c. of antimonic and arsenic acids.

Delesse finds some recent stalactitic formations of a bluish-white color, occurring in the galleries of a copper mine in Tuscany (Ann. d. M., IV. ix. 593), to consist of Silica 21·08, alumina 17·83, oxyd of copper 28·37, water 32·72=100.

Pyr., etc.—In the closed tube blackens and yields water. B.B. decrepitates, colors the flame emerald-green, but is infusible. With the fluxes gives the reactions for copper. With soda and charcoal a globule of metallic copper. Decomposed by acids without gelatinization.

Obs.—Accompanies other copper ores, occurring especially in the upper part of veins.

Bischof observes (Lehrb., ii. 1885) that silicate of copper may be formed through the action of an alkaline-, lime-, or magnesia-silicate on sulphate or nitrate of copper in solution. He also shows that this silicate is decomposed by carbonated waters, producing carbonate of copper. The alkaline silicates are furnished by the decomposing granite, and the sulphate of copper by altered pyritous copper. But L. Sæmann communicates to the author that he has seen specimens of chrysocolla from Chili, which have in the interior the fibrous structure and composition of pure malachite, showing that the whole was once malachite. The chrysocolla analyzed by Scheerer (anal. 7) occurs with feldspar, and is supposed to have resulted from the action of sulphate of copper on the feldspar. Some specimens of the chrysocolla are translucent and brittle on one part, and earthy, like decomposed feldspar, on the opposite.

Found in most copper mines in Cornwall; at Libethen in Hungary; at Falkenstein and Schwatz in the Tyrol; in Siberia; the Bannat; Thuringia; Schneeberg, Saxony; Kupferberg, Bavaria; South Australia; Chili, etc.

In Somerville and Schuyler's mines, New Jersey, at Morgantown, Pa., and at Wolcottville, Conn., chrysocolla occurs associated with red copper ore, native copper, and green malachite; in Pennsylvania, near Morgantown, Berks Co.; at Perkiomen; at Cornwall, Lebanon Co.; also with similar associated minerals, and with brown iron ore, in Nova Scotia, at the Basin of Mines; also in Wisconsin and Michigan, mixed with carbonate of copper.

Chrysocolla is from χρυσός, *gold*, and κόλλα, *glue*, and was the name of a material used in soldering gold. The name is often applied now to borax, which is so employed. But much of the ancient *chrysocolla* was a green stone containing copper as the coloring ingredient, and the best, as Dioscorides says, was that which was κατακόρως πρασίζουσα, or of a fine leek-green or prase color; and the island of Cyprus, which was named from its copper mines, was a prominent locality. Pliny says the mineral was named after the real *chrysocolla*, because it looked like it. It may have included carbonate of copper, as was true to some extent of the *chrysocolla* and *mountain-green* of the 16th, 17th, and 18th centuries. The *cæruleum montanum* of Wallerius included both chrysocolla and an earthy variety of the carbonate.

347. ALIPITE. Pimelit *Schmidt*, Pogg., lxi. 388, 1844. Alipit *Glock.*, 1845.

Massive; earthy.

H.=2·5. G.=1·44–1·46, Schmidt. Color apple-green. Not unctuous Adheres to the tongue.

Comp.—O. ratio for $\dot{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$, 1 : 3 : ½, nearly; whence $(\frac{1}{3}\dot{\text{H}}+\frac{2}{3}(\dot{\text{Ni}}, \dot{\text{Mg}}))\ddot{\text{Si}}$, if the water be basic; according to Schmidt (l. c.), $\ddot{\text{Si}}$ 54·63, $\dddot{\overline{\text{Al}}}$ 0·30, $\dot{\text{Ni}}$ 32·66, $\dot{\text{Fe}}$ 1·13, $\dot{\text{Mg}}$ 5·89, $\dot{\text{Ca}}$ 0·16, $\dot{\text{H}}$ 5·23 =100.

From Silesia.

Named from the Greek ἀλιπής, *not greasy*.

348. CONNARITE. Konarit *Breith.*, B. H. Ztg., xviii. 1, 1859.

Monoclinic? In small grains and crystals, with perfect brachydiagonal cleavage, and supposed to be like vivianite in crystallization.

H.=2·5–3. G.=2·459–2·619. Color yellowish, pistachio- and siskin-green, olive-green. Streak siskin-green. In thin lamellæ translucent. Fragile.

Comp.—O. ratio for $\dot{\text{Ni}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 3 : 1½, nearly; whence $(\frac{1}{3}\dot{\text{H}}+\frac{2}{3}\dot{\text{Ni}})\ddot{\text{Si}}+\frac{2}{3}\dot{\text{H}}$, if a third of the water be basic. Analysis by Winkler (B. H. Ztg., xxiv. 335):

$\ddot{\text{Si}}$	$\dddot{\overline{\text{Al}}}$	$\dddot{\overline{\text{Fe}}}$	$\dot{\text{Ni}}$	$\dot{\text{Co}}$	$\dot{\text{H}}$	$\overset{.....}{\overline{\text{P}}}$	$\overset{.....}{\overline{\text{As}}}$	$\dddot{\text{S}}$
43·6	4·6	0·8	35·8	0·6	11·1	2·7	0·8	*tr.*=100.

Obs.—Occurs at the Hanns George mine, at Röttis, in Saxon Voigtland, with röttisite.

Named from κόνναρος, *evergreen*.

349. PICROSMINE. Pikrosmin *Haid.*, Min. Mohs., iii. 157, 1825.

Orthorhombic. Cleavable massive. Also columnar or fibrous. Cleavage: in traces, parallel to a prism of 117° 49′; perfect parallel to i-$\breve{i}$, less so parallel to i-$\bar{i}$.

H.=2·5–3. G.=2·66, cleavable massive; 2·596, columnar. Lustre of cleavage-face pearly, elsewhere vitreous. Color greenish-white; also dark green, gray. Streak white. Subtranslucent—opaque. Odor bitter argillaceous when moistened. Double refraction strong; optical axes in the columnar variety in a longitudinal plane; bisectrix negative, normal to the sides of the columns.

Comp.—O. ratio for $\dot{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 2 : ½; $\dot{\text{Mg}}\ddot{\text{Si}}+\frac{1}{2}\dot{\text{H}}$=Silica 55·1, magnesia 36·7, water 8·2=100. Analysis by Magnus (Pogg., vi. 53):

$\ddot{\text{Si}}$ 54·89 $\dddot{\overline{\text{Al}}}$ 0·79 $\dddot{\overline{\text{Fe}}}$ 1·40 $\dot{\text{Mn}}$ 0·42 $\dot{\text{Mg}}$ 34·35 $\dot{\text{H}}$ 7·30=98·15.

Pyr., etc.—In the closed tube some ammonia given off with the water; the assay blackens and has a burnt smell. B.B. on charcoal whitens without fusing. With borax slowly dissolves to a transparent glass; affords a glass with little soda, and an infusible slag if the soda be increased. A pale and indistinct red with cobalt solution.

Obs.—Associated with magnetic iron ore at the iron mine of Engelsberg, near Pressnitz in Bohemia. The fibrous variety resembles asbestus.

Named from πικρός, *bitter*, and ὀσμ, *odor*.

Haidinger instituted the species on the physical characters and cleavage of the massive and fibrous mineral, without a knowledge of the chemical composition; and he suggests that much of common asbestus may belong to it.

The talcose or chloritic schist of Greiner in Tyrol, and the limestone of the vicinity of Waldheim, Saxony, are reported as other localities. Descloizeaux obtained the above optical characters from the Pressnitz mineral, and also from another from Zermatt.

350. SPADAITE. *V. Kobell*, Gel. Anz., München, xvii. 945, 1843, J. pr. Ch., xxx. 467.

Massive, amorphous.

H.=2·5. Lustre a little pearly or greasy. Translucent. Color reddish, approaching flesh-red. Fracture imperfect conchoidal and splintery.

Comp.—O. ratio for $\dot{R}$, $\ddot{S}i$, $\dot{H}$=5 : 12 : 4; whence, if a fourth of the water is basic, ($\frac{4}{5}\dot{M}g+\frac{1}{5}\dot{H}$)$\ddot{S}i+\frac{3}{5}\dot{H}$. Analysis by v. Kobell:

$\ddot{S}i$ 56·00 $\bar{A}l$ 0·66 $\dot{F}e$ 0·66 $\dot{M}g$ 30·67 $\dot{H}$ 11·34=99·38.

Pyr., etc.—In the closed tube yields much water and becomes gray. B.B. melts to a glassy enamel. Dissolves in concentrated muriatic acid, the silica easily gelatinizing.

Obs.—From Capo di Bove, near Rome, filling the spaces among crystals of wollastonite, in leucitic lava.

Named after Sign. Medici Spada.

QUINCITE.—The *quincite* of Berthier is in light carmine-red particles disseminated through a limestone deposit.

Comp.—Silica 54, magnesia 19, protoxyd of iron 8, water 17=98. From near the village of Quincy, France. Strong concentrated acids dissolve the magnesia and iron, and leave the silica in a gelatinous state. The color is attributed to organic matter.

351. PYRALLOLITE pt. 352. PICROPHYLL. 353. TRAVERSELLITE. 354. PITKARANDITE. 355. STRAKONITZITE. 356. MONRADITE.

These are names of pyroxene in different stages of alteration, between true pyroxene and either serpentine or steatite. For analyses and descriptions, see under that species (p. 221).

357. NEOLITE. Neolit *Scheerer*, Pogg., lxxi. 285, 1847.

In silky fibres stellately grouped; also massive.

H.=1–2. G.=2·77, after drying. Color green. Lustre silky or earthy.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{S}i$, $\dot{H}$ about 3 : 1 : 6 : 1½; whence the formula $\dot{M}g\ddot{S}i+\frac{1}{6}\dot{H}$ [$+\frac{1}{6}\bar{A}l\dot{H}^2$]. Perhaps ($\dot{R}^3$, $\bar{R}$, $\dot{H}^3$)$\ddot{S}i^4$. As the mineral is formed through the agency of infiltrating waters through rocks containing magnesia, it is not safe to assume that there are no impurities present. Analyses: 1–3, Scheerer (Pogg., lxxxiv. 373); 4, Richter (ib.):

	$\ddot{S}i$	$\bar{A}l$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$
1. Arendal	52·28	7·33	3·79	0·89	31·24	0·28	4·04=99·85.
2. "	47·35	10·27	7·92	2·64	24·73	—	6·28=99·19.
3. Eisenach	51·35	9·02	0·79	—	30·19	1·93	6·50=99·78.
4. "	51·44	8·79	$\bar{F}e$0·88	—	31·11	2·00	6·50=100·72

Obs.—Occurs in the iron mines of Arendal; and in cavities in basalt near Eisenach. Also compact massive and earthy in fissures at Rochlitz in the Riesengebirge, Bohemia, of a pistachio-green color, or brownish; G.=2·625 to 2·837. Herter & Porth (Jahrb. G. Reichs, x. 19) observe that this variety contains oxyd of zinc, oxyd of iron, lime, alumina, and copper, as impurities.

Named from νέος, *new*, and λίθος, *stone*.

358. PALIGORSKITE. Paligorskit *T. v. Saaftschenkof*, Verh. Min. St. Pet., 1862, 102.

Fibrous. Soft, but tough, and hence with great difficulty pulverized. G.=2·217. Color white.

COMP.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{S}i$, $\dot{H}$, after excluding 8½ p. c. of what is called hygroscopic water, 1 : 2·5 : 8 : 3.

Analysis by Saaftschenkof (l. c.): $\ddot{S}i$ 52·18, $\bar{A}l$ 18·32, $\dot{M}g$ 8·19, $\dot{C}a$ 0·59, $\dot{H}$ 12·04, hygrosc. water 8·46=99·78. B.B. infusible. Not acted on by the acids.

From the Permian mining district of the Ural, "in der Paligorischen Distanz" of the second mine on the river Popovka. Probably an altered asbestus.

359. XYLOTILE *Glocker*, Synopsis, 97, 1847 (*Bergholz*, of Sterzing, and *Holzasbest*), approaches the above in constitution, but is probably only an altered asbestus. It occurs delicately fibrous; glimmering in lustre; wood-brown, light or dark, and also green in color; with G.=2·4–2·45 for

the brown, and 2·56 for the greenish, Kenngott. Thaulow obtained (Pogg., xli. 635) $\ddot{\text{Si}}$ 55·58, $\overline{\text{Al}}$ 0·04, $\overline{\text{Fe}}$ 19·44, $\dot{\text{Mg}}$ 15·50, $\dot{\text{Ca}}$ 0·10, $\dot{\text{H}}$ 10 27=79·93. Von Hauer finds (Sitz. Wien. Akad., xi. 388)·

	$\ddot{\text{Si}}$	$\overline{\text{Fe}}$	$\dot{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$
1.	44·31	17·74	3·73	8·90	2·27	21·57
2	45·53	18·03	3·36	11·08	*tr.*	22·01
3.	47·96	16·05	1·87	12·37	*tr.*	21·64

Of the water in the analyses, 9·20, 7·90, and 8·13 p. c. passed off at 100° C.; and, excluding the mean of these determinations, reduces the mean of the above results to $\ddot{\text{Si}}$ 50·43, $\overline{\text{Fe}}$ 18·97, $\dot{\text{Fe}}$ 3·28, $\dot{\text{Mg}}$ 11·82, $\dot{\text{Ca}}$ 0·85, $\dot{\text{H}}$ 14·63=99·98.

Kenngott considers it as probably altered chrysotile.

Xylite of Hermann is also probably only a hydrous asbestus. It has a brown color and asbestiform structure. Hermann obtained (J. pr. Ch., xxxiv. 180, 1845), $\ddot{\text{Si}}$ 44·06, $\overline{\text{Fe}}$ 37·84, $\dot{\text{Ca}}$ 6·58, $\dot{\text{Mg}}$ 5·42, $\dot{\text{Cu}}$ 1·36, $\dot{\text{H}}$ 4·70=99·96. H.=3. G.=2·935.

360. ANTHOSIDERITE. *Hausm.*, Gel. Anz. Gött., 281, 1841.

In tufts of a fibrous structure, and sometimes collected into feathery flowers. Resembles cacoxene.

H.=6·5. G.=3. Lustre silky, a little chatoyant on a fresh fracture. Color ochre-yellow and yellowish-brown, somewhat grayish, rarely white. Powder brown to colorless. Opaque or slightly subtranslucent. Gives sparks with a steel. Tough.

Comp.—$\overline{\text{Fe}}^2\ddot{\text{Si}}^9+2\dot{\text{H}}$=Silica 60·3, sesquioxyd of iron 35·7, water 4·0=100. Analysis by Schnedermann (l. c., and Pogg., lii. 292) of the yellow variety (mean of two results): $\ddot{\text{Si}}$ 60·08, $\overline{\text{Fe}}$ 34·99, $\dot{\text{H}}$ 3·59=98·66. If the water is basic, the O. ratio is 1 : 2¼.

Pyr., etc.—B.B. becomes reddish-brown, then black, and fuses with difficulty to a black magnetic slag. Decomposed by muriatic acid.

Obs.—From Antonio Pereira, in the province Minas Geraes, Brazil, where it is intimately associated with magnetic iron. Named from ἄνθος, *flower*, and σίδηρος, *iron*.

Twins. Cleavage: *I*, perfect; *O*, in traces. Also stalactitic, mammillated, botryoidal, and fibrous forms; also massive and granular.

H.=4·5—5, the latter when crystallized. G.=3·16—3·9, 3·43—3·49, from Altenberg. Lustre vitreous, *O* subpearly, sometimes adamantine. Color white; sometimes with a delicate bluish or greenish shade; also yellowish to brown. Streak white. Transparent —translucent. Fracture uneven. Brittle. Pyroelectric. Double refraction strong; optic-axial plane *i*-ī; divergence 81°—82½° for the red rays; bisectrix positive, normal to *O*.

Var.—1. *Ordinary.* (*a*) In crystals. Measured angles: *I*∧*i*-ĭ=128° 4′, Schrauf, giving *I*∧*I*=103° 52′; *I*∧*i*-ĭ=151° 12′, Schrauf; *i*-2 ∧ *i*-ĭ=147° 25′, Hessenberg; *O* ∧ 1-ī=148° 31′, Dauber, 148° 39′, Schr.; *O* ∧ 3-ī=118° 39′, Dauber, 118° 40′ Schr.; *O* ∧ 1-ĭ=154° 31, Daub., 154° 27′, Schr. (*b*) Mammillary or stalactitic. (*c*) Massive; often cellular. *Wagite* is a concretionary light-blue to green calamine from Nijni Jagurt in the Ural; G.=2·707.

2. *Carbonated.* Sullivan has described (Dublin Q. J. Sci., 1862, ii. 150) a variety of calamine from the Dolores mine in the province of Santander, Spain, occurring in concentric pisolitic masses, frequently containing a semitranslucent, opal-like nucleus. This mineral, produced from the hydrous carbonate by the action of silicated waters, contains from 12 to 20 per cent. of carbonate of zinc; G.=2·88—3·69. Sullivan's paper is one of much interest.

3. *Argillaceous.* Another calamine from Spain, analyzed by Schönichen (B. H. Ztg., xxii. 163), contains 20 to 26 p. c. of alumina, with 31·5 p. c. of silica, 21 to 28·5 p. c. of oxyd of zinc, and 18 to 20 of water; and is apparently calamine mixed with clay. It occurs massive; color at first white, changing in the air to violet, brown, and finally black; transparent on the edges; feel soapy.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 1 : ½; $\dot{\mathrm{Z}}\mathrm{n}^2\ddot{\mathrm{Si}}+\dot{\mathrm{H}}$=Silica 25·0, oxyd of zinc 67·5, water 7·5 =100. Perhaps in some, or all cases, one-third more water, or $\dot{\mathrm{Z}}\mathrm{n}^2\ddot{\mathrm{Si}}+1\tfrac{1}{3}\dot{\mathrm{H}}$=Silica 24·4, oxyd of zinc 65·9, water 9·7=100.

Analyses: 1, Smithson (Nicholson's Journ., vi. 78); 2, 3, Monheim (J. pr. Ch., xlix. 319); 4, Berzelius (Ak. H. Stockh., 1819, 141); 5, Berthier (J. d. M., xxviii. 341); 6, Thomson (Phil. Mag., 1840); 7, 8, Hermann (J. pr. Ch., xxxiii. 98); 9, E. Schmidt (J. pr. Ch., li. 257); 10, C. Schnabel (Pogg., cv. 144); 11, Radoszkovski (l. c.):

The *wagite* gives the O. ratio 1 : 1 : ½.

Pyr., etc.—In the closed tube decrepitates, whitens, and gives off water. B.B. almost infusible (F.=6); moistened with cobalt solution gives a green color when heated. On charcoal with soda gives a coating which is yellow while hot, and white on cooling. Moistened with cobalt solution, and heated in O.F., this coating assumes a bright green color. Gelatinizes with acids even when previously ignited. Decomposed by acetic acid with gelatinization. Soluble in a strong solution of caustic potash.

Obs.—Calamine and smithsonite are usually found associated in veins or beds in stratified calcareous rocks accompanying ores of blende, iron, and lead, as at Aix la Chapelle; Raibel and Bleiberg, in Carinthia, in the upper Triassic; Moresnet in Belgium, Fribourg in Brisgau, Iserlohn, Tarnowitz, Olkucz, Miedzanagora, Retzbanya, Schemnitz. At Roughten Gill, in Cumberland, in acicular crystals and mammillary crusts, sky-blue and fine green; at Alston Moor, white; at the Rutland mine, near Mattock, in Derbyshire, in brilliant crystals, and grayish-white, and yellow, and mammillated: at Castleton, in crystals; on the Mendip Hills, mostly brownish-yellow, and in part stalactitic; in Flintshire, etc., Wales; Leadhills, Scotland. Large crystals have been found at Nertschinsk.

In the United States occurs with smithsonite in Jefferson county, Missouri. In Pennsylvania, at the Perkiomen and Phenixville lead mines; in a lower Silurian rock two miles from Bethlehem, at Friedensville, in Saucon valley, abundant and extensively worked; on the Susquehanna, opposite Selinsgrove. Abundant in Virginia, at Austin's mines in Wythe Co. A pale yellow, fusible zinciferous clay occurs in considerable abundance with calamine at the Ueberroth mine, Friedensville. Analysis of this by John M. Blake gave $\ddot{Si}$ 41·36, $\bar{A}l$ 8·04, $\bar{F}e$ 9·55, $\dot{Z}n$ 32·24, $\dot{M}g$ 1·02, $\dot{K}$ *tr.*, $\dot{H}$ 7·76. Other specimens examined by W. T. Roepper gave a variable amount of zinc, showing that the substance is not homogeneous (priv. contrib.).

On cryst. see G. Rose, Pogg., lix.; Dauber, Pogg., xcii. 245 (whose measurements are above adopted); Hessenberg, Senk. Nat. Ges. Frankfurt a M., ii. 260; Schrauf, Ber. Ak. Wien, xxxviii. 789; Descl. Min., i. 117.

The name *Calamine* (with *Galmei* of the Germans) is commonly supposed to be a corruption of *Cadmia*. Agricola says it is from *calamus*, a *reed*, in allusion to the slender forms (stalactitic) common in the *cadmia fornacum*.

The *cadmia* of Pliny and of other ancient authors included both the native silicate and carbonate, and the oxyd from the chimneys of furnaces (cadmia fornacum). The two native ores continued to be confounded under the name *lapis calaminaris*, *calamine* or *galmei*, until investigated chemically by Smithson in 1803. Earlier analyses had made out chemical differences, and some authors, before 1790, had rightly suggested a division of the species: Bergmann having found 28 p. c. carbonic acid in a Holywell specimen (J. de Phys., xvi. 17, 1780); and Pelletier, in a kind from Fribourg in Brisgau, which had been called *Zeolite of Brisgau* because it gelatinized with acids, 52 p. c. silica, with 36 oxyd of zinc, and 12 water (J. de Phys., xx. 420, 1782); and Klaproth, in another, similarly gelatinizing, 66 oxyd of zinc and 33 silica. But Smithson was the first to make known the true composition, and clear away all doubts.

De Lisle noticed the crystalline forms of the two species, describing one kind as prismatic with dihedral summits, and the other as scalenohedral like dogtooth spar, yet did not fully appreciate the importance of the observation; while Haüy, 14 years later, in his *Traité*, describes only the crystals of the *silicate*, and takes the ground that the *zinc carbonatée* was only an impure calcareous "zinc oxydé."

In 1807 Brongniart called the silicate *calamine*, leaving for the other ore the chemical name *zinc carbonatée*. In 1832, Beudant followed Brongniart in the former name, and designated the latter *Smithsonite*, after SMITHSON, who had analyzed in 1803 the carbonate as well as silicate. Thus the two species were at last, not only distinguished, but mineralogically named.

Unfortunately, Brooke & Miller, in 1852, reversed Beudant's use of these names, with no good reason; and in 1853, Kenngott, on account of the confusion of names, as he says, introduced for the silicate the new name *Hemimorphite*, and so added to the confusion. These innovations should have no favor.

361A. **MORESNETITE** *Risse* (Verh. nat Ver. Bonn, 1865, Ber. 98). A mineral from Altenberg, near Aachen, occurring with calamine. Two varieties are found, one dark to leek-green and opaque; the other light emerald-green, transparent. The latter is the purest; it has H.=2·5, conchoidal fracture, streak white. It afforded on analysis $\ddot{Si}$ 30·31, $\bar{A}l$ 13·68, $\dot{F}e$ 0·27, $\dot{N}i$ 1·14, $\dot{Z}n$ 43·41, $\dot{M}g$ *tr.*, $\dot{C}a$ *tr.*, $\dot{H}$ 11·37=100·18. B.B. on charcoal gives with cobalt solution a pale green mass. Difficultly soluble in acids.

362. VILLARSITE. *Dufrenoy*, C. R., 1842, Ann. d. M., IV. i. 387, 1842. Serpentin aus d. Malenkerthal *Fellenberg*, J. pr. Ch., ci. 38, 1867.

Orthorhombic. $I \wedge I=120° \ 8'$, Descl. Observed planes: O, 1-$\bar{\imath}$, 1; crystals all compound, consisting of three intersecting individuals; composition-face i-$\bar{\imath}$. $O \wedge 1\text{-}\bar{\imath}=140° \ 36'$, $O \wedge 1=136° \ 32'$. (Crystallization perhaps pseudomorphic.) Mostly in rounded grains. Also massive.

H.=4–5. G.=2·978, from Traversella; 2·99, fr. Malenkerthal. Color yellowish-green to olive-green; also dark green to blackish. Streak uncolored. Translucent; transparent in thin plates Double refraction strong; optic-axial plane, *i-ī*; bisectrix normal to *O*, positive; Descl.

Comp.—O. ratio for Ṙ, S̈i, Ḣ=1 : 1 : ¼; ($\frac{11}{12}$ Ṁg+$\frac{1}{12}$ Ḟe)^3 S̈i+¾ Ḣ=Silica 38·9, magnesia 47·5, protoxyd of iron 7·8, water 5·8=100. Appears to be a hydrous forsterite or boltonite in composition, and to resemble much the latter. G. Rose pointed out the approximation in angle to chrysolite, and regarded it as an altered variety. Its occurrence in twins of three intersecting crystals, as made known by Descloizeaux (Min., 95, 1862), is an important characteristic not thus far observed in forsterite, or any other species of the chrysolite group. The crystals have the planes shining, but not quite even. Analyses: 1, 2, Dufrenoy (l. c., and Dufr. Min., 2d. ed., iv. 343); 3, Fellenberg (l. c.):

	S̈i	Ḟe	Ṁn	Ṁg	Ċa	K̇	Ḣ
1. Traversella	39·61	3·59	2·42	47·37	0·53	0·46	5·80=99·78 Dufrenoy.
2. Forez	40·52	6·25	—	43·75	1·70	0·72	6·21=99·15 Dufrenoy.
3. Malenkerthal (⅔)	41·72	7·97	—	42·15	—	—	5·55, Ċr, Ṅi 0·75, Äl 3·19=101·33 F.

Anal. 1 is of the original villarsite; 2, of grains from the granite of Forez and Morvan, France.

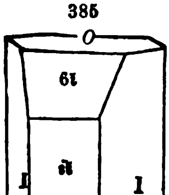
Pyr., etc.—B.B. infusible. With borax a green enamel. Attacked by concentrated acids.

Obs.—At Traversella it is associated with mica, quartz, and dodecahedral magnetite. Much boltonite is hydrous, and in composition belongs here. Grains in the interior of the serpentine pseudomorphs of Snarum have sometimes a similar composition. The mineral from Pirlo in Malenkerthal, of the Grisons, constitutes the base of a serpentine-like rock, which is slightly crystalline in texture, somewhat slaty, feeble lustre, and between blackish-gray and dark green in color. Supposing the alumina present as a mixed silicate, the formula is that of the Traversella minéral. The rock looks like a mixture of several minerals.

363. PREHNITE. Chrysolite *Sage*, Min., i. 232, 1777. Chrysolite du Cap (a kind of Schorl) *de Lisle*, ii. 275, 1783. Zeolithe verdâtre *v. Born*, Cat. de Raab, i. 203, 1790. Prehnit *Wern.*, Bergm. J., 1790, i. 110; anal. by *Klapr.*, Schrift Ges. nat. Berlin, viii. 217, 1788. Koupholite (fr. Barèges), *Picot la Peyrouse*, *Delameth.*, T. T., ii. 547, 1797. Ædelite (Edelite) *Walmstedt*, Jahresb., v. 217, 1825. Jacksonite *Whitney*, J. Nat. H. Soc. Boston, v. 487, 1847.

Orthorhombic. *I* ∧ *I*=99° 56′, *O* ∧ 1-*ī*=146° 11½′; *a* : *b* : *c*=0·66963 : 1 : 1·19035. Observed planes: *O*; vertical, *I*, *i-ĭ*, *i-ī*; domes, ¾-*ī*, $\frac{3}{2}$-*ī*, 6-*ĭ*; octahedral, 2, 6. *O* ∧ ¾-*ī*≐153° 20′, *O* ∧ $\frac{3}{2}$-*ī*=134° 52½′, *O* ∧ 2=119° 45′, *O* ∧ 6=100° 47′ *O* ∧ 6-*ĭ*=106° 30′, *I* ∧ *i-i*=130° 2′. Cleavage: basal, distinct. Tabular crystals often united by *O*, making broken forms, often barrel-shaped. Reniform, globular, and stalactitic with a crystalline surface. Structure imperfectly columnar or lamellar, strongly coherent; also compact granular or impalpable.

385



H.=6–6·5. G.=2·8–2·953. Lustre vitreous; *O* weak pearly. Color light green, oil-green, passing into white and gray; often fading on exposure. Subtransparent—translucent; streak uncolored. Fracture uneven. Somewhat brittle. Pyroelectric, with polarity central, the analogue poles at the centre of the base and the antilogue at the extremities of the brachydiagonal, Riess & Rose. Double refraction strong; optic-axial plane usually *i-ĭ*; bisectrix positive, normal to *O*; axial angle 122°—130°, for crystals from Dauphiny and Pyrenees, but in others much less; divergence very slightly diminished by heating; Descl.

Var.—Usual in firm and hard incrusting masses, externally globular or mammillary, the surface made up often of grouped crystals more or less imperfect, but sometimes smooth.

Coupholite is in cavernous masses, made of small, thin, fragile laminæ or scales; the original was from the peak of Eresalida, near Barèges, in the Pyrenees; also reported from the Col du Bonhomme, at the foot of Mt. Blanc. Named from *κοῦφος, tender.*

Edelite (or *Ædelite*) is nothing but prehnite from Ædelfors, Sweden.

Jacksonite (or *anhydrous prehnite*) of Whitney is ordinary prehnite, from Keweenaw Pt. and Isle Royale.

Crystals from Farmington, Ct., have for the optic-axial plane $i\text{-}\bar{i}$; and the divergence for the red rays in the outer parts of a plate of a crystal, 48°—50°; in an interior wedge-shaped part of the same plate, 17°, Descl. The dispersion is very strong in these crystals, while in those of Dauphiny it is hardly perceptible.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}=2:3:6:1$, whence, if the water is basic, for bases and silica, 1 : 1; and formula $(\frac{1}{6}\dot{\text{H}}^3+\frac{2}{6}\dot{\text{C}}\text{a}+\frac{3}{6}\bar{\text{A}}\text{l})^3\,\ddot{\text{Si}}^3$=Silica 43·6, alumina 24·9, lime 27·1, water 4·4=100. Analyses: 1, 2, Gehlen (Schw. J., iii. 171); 3–5, Walmstedt (Jahresb., v. 217); 6, 7, Thomson & Lehunt (Min., i. 275); 8, Regnault (Ann. d. M., III. xiv. 154); 9, Amelung (Ramm. 2d Suppl., 118, Pogg., lxviii. 312); 10, 11, Leonhard (Pogg., liv. 579); 12, Domeyko (Ann. d. M., IV. ix. 3); 13, P. Kützing (B. H. Ztg., xx. 267); 14, C. W. Paykull (Œfv. Ak. Stock., 1866, 85):

14. Upsala	44·11	22·99	3·22	25·83	4·26=100·41 Paykull.	

No. 10 is a pseudomorph after analcite, and 11 after leonhardite. The *jacksonite*, or *anhydrous prehnite*, of Whitney (l. c.), contains, according to Jackson and Brush, 4·7, 4·15 (J.), and 4·85 (B.) p. c. of water. The specimen analyzed by Whitney may possibly have been calcined, as in some localities on Lake Superior it is customary to burn the copper ore to free it from adhering rock. He obtained (l. c.) $\ddot{\text{Si}}$ 46·12, $\bar{\text{A}}$l 25·91, $\dot{\text{C}}$a 27·03, $\dot{\text{N}}$a 0·85=99·91.

Pyr., etc.—In the closed tube yields water. B.B. fuses at 2 with intumescence to a blebby enamel-like glass. Decomposed by muriatic acid without gelatinizing. *Coupholite*, which often contains dust or vegetable matter, blackens and emits a burnt odor.

Obs.—Occurs in granite, gneiss, syenite, dioryte, and trappean rocks, especially the last.

At St. Christophe and l'Armentières, near Bourg d'Oisans in Isère, associated with axinite and epidote; at Ratschinges, Fassa valley, and near Campitello, Tyrol; in Salzburg; Ala in Piedmont; the Sau-Alp in Carinthia; Joachimsthal in Bohemia; in Nassau, at Oberscheld and Uckersdorf; near Freiburg in Brisgau on the Rosskopf; in the Harz, near Andreasberg, with datolite; Arendal, Norway; Ædelfors in Sweden (*edelite*); Upsala, Sweden, in rifts in hornblendic granite, the decomposition of the hornblende having afforded the lime, and of the mica, the alumina (Paykull); at Friskie Hall and Campsie in Dumbartonshire, and at Hartfield Moss; in Renfrewshire, in veins traversing trap, associated with analcite and thomsonite; also at Corstorphine Hill, the Castle and Salisbury Crag, near Edinburgh; Mourne Mts., Ireland.

In the United States, finely crystallized at Farmington, Woodbury, and Middletown, Conn., and West Springfield, Mass., and Patterson and Bergen Hill, N. J.; in small quantities in gneiss, at Bellows Falls, Vt.; in syenite, at Charlestown, Mass; Milk Row quarry, often in minute tabular crystals, with chabazite; also at Palmer (Three Rivers) and Turner's Falls, Mass., on the Connecticut, in trap, and at Perry, above Loring's Cove, Maine; at Westport, Essex Co., N. Y. (*chiltonite* Emmons), on a quartzose rock; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac; in large veins in the Lake Superior copper region, often occurring as the veinstone of the native copper, sometimes including strings or leaves of copper; and at times in radiated nodules disseminated through the copper.

Handsome polished slabs of this mineral have been cut from masses from China.

The formula $(\frac{1}{2}\dot{\text{R}}^3+\frac{1}{2}\bar{\text{A}}\text{l})^2\,\ddot{\text{Si}}^3$ is analogous to that of chrysolite in the ratio 1 : 1, and the two species appear to be homœomorphous, $2\text{-}\breve{i} \wedge 2\text{-}\breve{i}$ in chrysolite=99° 7′.

Alt.—Prehnite occurs altered to green earth and feldspar.

Named by Werner in 1790 after Col. Prehn, who first found the mineral at the Cape of Good

Hope. Sage had called it (1777) *chrysolite*, and Romé de Lisle had referred it (1753, to the group of *schorl*.

363A. UIGITE *Heddle* (Ed. N. Phil. J., II. iv. 162, 1856). In radiated sheafy clusters of plates, in nests in the amygdaloid of Uig, Isle of Skye, along with analcite and faroelite. H.=5·5; G.=2·284; lustre pearly; color white, slightly yellowish. Composition, according to Heddle (loc. cit.), $\ddot{\mathrm{Si}}$ 45·98, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 21·93, $\dot{\mathrm{C}}\mathrm{a}$ 16·15, $\dot{\mathrm{N}}\mathrm{a}$ 4·7, $\dot{\mathrm{H}}$ 11·25. The O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$ corresponding is near 1 : 2 : 4. B.B. fuses readily and quietly to an opaque enamel, which is not frothy; gives a strong soda reaction.

It appears to be near prehnite in structure, and needs further investigation.

364. CHLORASTROLITE. *C. T. Jackson*; *J. D. Whitney*, J. Nat. Hist. Bost., v. 488.

Massive. Finely radiated or stellate in structure.

H.=5·5–6. G.=3·180. Lustre pearly. Color light bluish-green Slightly chatoyant on the rounded sides.

Comp.—O. ratio 1 : 2 : 3 : 1; $(\dot{\mathrm{C}}\mathrm{a}^3, \dot{\mathrm{N}}\mathrm{a}^3)^2\ddot{\mathrm{Si}}^3+2(\dddot{\bar{\mathrm{A}}}\mathrm{l}, \dddot{\bar{\mathrm{F}}}\mathrm{e})^2\ddot{\mathrm{Si}}^3+6\dot{\mathrm{H}}=(\tfrac{1}{3}\dot{\mathrm{R}}^3+\tfrac{2}{3}\dddot{\bar{\mathrm{R}}})^2\ddot{\mathrm{Si}}^3+2\dot{\mathrm{H}}$=Silica 37·6, alumina 24·6, sesquioxyd of iron 6·4, lime 18·7, soda 5·2, water 7·5=100. Analyses by Whitney (Rep. G. Lake Sup., 1851, ii. 97):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$, little $\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	36·99	25·49	6·48	19·90	3·70	0·40	7·22=100·18.
2.	37·41	24·25	6·26	21·68	4·88		5·77=100·25.

Rammelsberg observes that it has some relation in composition to a hydrous epidote. It also approaches carpholite.

Pyr., etc.—In the closed tube yields water and becomes white. B.B. fuses easily with intumescence to a grayish blebby glass. Forms a transparent glass readily with borax, tinged with iron Soluble in muriatic acid, the silica separating as a flocky precipitate (Whitney).

Obs.—Occurs on the shores of Isle Royale, Lake Superior, in small rounded pebbles, which have come from the trap, and are waterworn; it receives a fine polish.

Named from χλωρός, *green*, ἄστρον, *star*, λίθος, *stone*.

365. TRITOMITE. Tritomit *Weibye & Berlin*, Pogg., lxxix. 299, 1850.

Isometric; tetrahedral, f. 31. Cleavage indistinct.

H.=5·5. G.=3·9–4·66; 3·908, Forbes; 4·16–4·66, W. & B.; 4·26, Möller. Lustre submetallic, vitreous. Color dull brown. Streak dirty yellowish-gray. Subtranslucent.

Comp.—$(\dot{\mathrm{R}}^3, \ddot{\mathrm{R}}^{\frac{3}{2}}, \dddot{\bar{\mathrm{R}}})^2\ddot{\mathrm{Si}}^2+4\dot{\mathrm{H}}$? Analyses: 1, approximate, N. J. Berlin (l. c.); 2, D. Forbes (Ed. N. Phil. J., II. iii. 1856):

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{W}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{e}$	$\dot{\mathrm{L}}\mathrm{a}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{Y}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{H}}$	
1.	20·13	4·62[a]	2·24	40·36	15·11	1·88	—	0·46	0·22	5·15	1·46	7·86=99·44	Berlin.
2.	21·16	3·95[b]	2·86	37·64	12·41	2·68	1·10	4·64	0·09	4·04	0·33	8·68=99·58	Forbes.

[a] With $\mathrm{Mn\,O, Cu\,O, Sn\,O^2}$. [b] With $\mathrm{Sn\,O^2}$.

F. P. Möller has obtained a very different composition in, apparently, a careful analysis, in which the state of oxydation of the bases was ascertained (Ann. Ch. Pharm., cxx. 241):

$\ddot{\mathrm{Si}}$	$\ddot{\mathrm{S}}\mathrm{n}$	$\dddot{\mathrm{T}}\mathrm{a}$ $\ddot{\mathrm{Z}}\mathrm{r}$?	$\dddot{\bar{\mathrm{C}}}\mathrm{e}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dddot{\bar{\mathrm{M}}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{e}$	$\dot{\mathrm{L}}\mathrm{a}$, $\dot{\mathrm{D}}\mathrm{i}$	$\dot{\mathrm{Y}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{B}}\mathrm{a}$	$\dot{\mathrm{S}}\mathrm{r}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
15·38	0·74	3·63	4·48	1·61	2·27	0·49	10·66	44·05	0·42	0·16	6·41	0·19	0·71	0·56	2·10	5·63=99·49

From Berlin and Forbes, the formula $\dddot{\bar{\mathrm{R}}}^2\ddot{\mathrm{Si}}^3+4\dot{\mathrm{H}}$ has been deduced. Möller obtains the O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$ 4 : 1 : 4 : 2. But if the $\ddot{\mathrm{S}}\mathrm{n}$, $\dddot{\mathrm{T}}\mathrm{a}$, $\ddot{\mathrm{Z}}\mathrm{r}$ are added to the bases instead of the silica, the oxygen ratio for all the bases to the silica and water is very nearly 2 : 1 : $\frac{2}{3}$.

Forbes questions whether the crystals observed are not thorite.

Pyr., etc.—Yields water and gives a weak fluorine reaction; with borax a reddish-yellow glass, which is colorless on cooling. With muriatic acid in powder yields chlorine, and gelatinizes.

Obs.—From the island Lamö, near Brevig, Norway, with leucophanite and mosandrite in a coarse syenite.

Named from τρίς, *three-fold*, and τέμνω, *to cut*, alluding to the trihedral cavities which the crystals leave in the gangue.

365. THORITE. Thorit *Berz.*, Ak. H. Stockh., 1829. Orangit *Bergemann*, Pogg., lxxxii. 561, 1851

Isometric and tetrahedral. In dodecahedral crystals, with octahedral planes tetrahedrally developed, the larger set dull and even, the smaller bright and rounded, and with the three edges about the latter replaced. Also massive and compact.

H.=4·5—5. G.=4·3—5·4; of purest, 5—5·4. Lustre of surface of fresh fracture vitreous to resinous. Color orange-yellow, brownish-yellow; also black, inclining to brown. Streak light orange to dark brown. Transparent in thin splinters to nearly opaque. Fracture conchoidal. Easily frangible. Optically uniaxial.

Var.—The brownish-black and black variety, from Lövö, Norway, was the mineral from which Berzelius obtained the metal thorium, and which received the name *thorite*. The yellowish variety is the *orangite* (so called from the color), from Langesund fiord, which Bergemann, when he so named it, supposed to contain a new metal, called by him *donarium*. The latter has since been found with an exterior of the former. The mineral occurs as pseudomorphs after orthoclase and zircon, and crystals of the latter kind have afforded Zschau (Am. J. Sci., II. xxvi. 359) the angles *I* ∧ 1=132½°, 1 ∧ 1=123¼°, the corresponding angles of zircon being 132° 10′ and 123° 19′. Zschau regards the mineral thorite as tetragonal, and isomorphous with zircon, not considering his crystals as pseudomorphous.

The mineral varies much in specific gravity, *orangite* affording 5·397, Bergemann; 5·34, Krantz; 5·19, Damour; 4·888—5·205, Chydenius; and *thorite*, 4·680, Berz.; 4·686, Bergemann; 4·344—4·397, Chydenius.

Comp.—Essentially $\ddot{Th}\ddot{Si}+1\frac{1}{3}\dot{H}$=Silica 17·0, thoria 76·2, water 6·8=100; for the black thorite (anal. 1) $\ddot{Th}\ddot{Si}+2\dot{H}$=Silica 16·4, thoria 73·8, water 9·8=100. Analyses: 1, Berzelius (l. c.), 2, Damour (Ann. d. M., V. i. 587); 3, Bergemann (l. c.); 4, Chydenius (Pogg., cxix. 43):

	$\ddot{Si}$	$\ddot{Th}$	$\ddot{Sn}$	$\ddot{\bar{Al}}$	$\ddot{\bar{Fe}}$	$\ddot{\bar{Mn}}$	$\ddot{\bar{U}}$	$\dot{Pb}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$
1.	18·98	57·91	0·01	0·06	8·40	2·39	1·61	0·80	0·36	2·58	0·10	0·14	9·50, undis. 1·70=99·51 Berz.
2.	17·52	71·65	—	0·17	0·31	0·28	1·13	0·88	*tr.*	1·59	0·88	0·14	6·14=100·14 Damour.
3.	17·70	71·25	—	—	0·31	0·21	—	—	4·04	—		0·30	6·90, $\dot{Ca}\ddot{C}$ 4·04=100·74 B.
4.	17·76	73·80	—	—	—	—	—	1·18	*tr.*	1·08	—	—	6·45=100·27 Chydenius.

Pyr., etc.—In the closed tube yields water; the orange variety becomes dull-brown, and, on cooling, orange again. B.B. on charcoal infusible, the edges only being slightly glazed; with borax a yellowish pearl, becoming colorless on cooling; with salt of phosphorus a colorless glass, which becomes milky and greenish on cooling; with borax an orange glass when hot, which becomes grayish on cooling. A little nitre being added, the orange color remains after cooling. With muriatic acid easily forms a jelly before, but not after, calcination. The black thorite becomes pale brownish-red when heated; and on charcoal forms a yellowish-brown slag.

Obs.—Found in syenite by Esmark at Lövö, near Brevig, in Norway; also at Langesund fiord, near Brevig (orangite, anal. 2–4). Masses of orangite weighing several ounces have been obtained. The black thorite appears to be partially altered.

367. CERITE. Ferrum calciforme terra quadam incognita intime mixtum, Tungsten von Bastnäs, *Cronstedt*, Ak. H. Stockholm., 1751, Min., 183, 1758. Cerit *His. & Berz.*, Cerium en ny Metal, etc., 1804, Gehlen's J., ii. 397, 1804, Afh., i. 58, 1806. Ochroit, *Klapr.*, Gehlen's J. ii. 303, 1804. Cererit *Klapr.*, Beitr., iv. 140, 1807; *Karst.*, Tab., 74, 1808. Cerium oxydé siliceux *H.*, Tabl., 1809. Cerin-Stein *Wern.*, Hoffm. Min., iv. a, 286, 1817. Kieselcerit *Germ.* Silicate of Cerium. Lanthanocerit *Hermann*, J. pr. Ch., lxxxii. 406, 1861.

Hexagonal? Isometric? In short six-sided prisms, Haid. Commonly massive; granular.

H.=5·5. G.=4·912, Haidinger. Lustre dull adamantine or resinous. Color between clove-brown and cherry-red, passing into gray. Streak grayish-white. Slightly subtranslucent. Brittle; fracture splintery.

Comp.—O. ratio for $\dot{R}$, $\ddot{Si}$, $\dot{H}$=1 : 1 : ½; ($\dot{C}e$, $\dot{L}a$, $\dot{D}i$)² $\ddot{Si}$+$\dot{H}$=Silica 20·4, ceria 73·5, water 6·1=100. Analyses: 1, Hisinger (Afh., iii. 287); 2, Hermann (J. pr. Chem., xxx. 193, and lxxxii. 407); 3, Kjerulf (Ann. Ch. Pharm., xxxvii. 12); 4, Rammelsberg (Pogg., cvii. 632, and Min. Ch., 547); 5, Hermann (J. pr. Ch., lxxxii. 406):

	$\ddot{Si}$	$\dot{F}e$	$\dot{C}e$	$\dot{L}a$	$\dot{D}i$	$\dot{C}a$	$\dot{H}$
1. Bastnäs	18·00	1·80		68·59		1·25	9·60=99·24 Hisinger.
2. "	16·06	3·17	26·55	16·83	18·05	3·56	8·10, $\bar{\bar{A}}l$ 1·68, $\dot{M}n$ 0·27, $\dot{M}g$ 1·25, $\ddot{C}$ 4·62 H
3. "	21·30	4·98	58·50	8·47		1·23	5·52=100 Kjerulf.
4. "(½)	19·18	1·54	64·55	7·28		1·31	5·71=99·57 Rammelsberg.
5. "	21·35	1·46	60·99	3·51	3·90	1·65	6·31, $\ddot{C}$ 0·83=100 Hermann.

From analysis 3, 3·27 of molybdenite, and 0·18 bismuth glance, are removed as impurities. Analyses 1 and 2 give near 10 p. c. of water, with much lanthanum and didymium, and little cerium, according to Hermann; he accordingly applies to this kind the distinctive name *lanthanocerite*, and to the rest that of *cerite*.

Klaproth, who published the first analysis (Beitr., iv. 140), and gave the mineral the name *ochroite*, obtained $\ddot{Si}$ 34·5, $\dot{C}e$ 54·5, $\dot{F}e$ 3·5, $\dot{C}a$ 1·25, $\dot{H}$ 5·0=98·75; with his silica he included all the material not decomposed in his method of analysis. Hermann has supposed the substance analyzed a distinct species.

Pyr., etc.—In a matrass yields water. B.B. infusible alone; with borax in the outer flame forms a yellow globule, which becomes almost colorless on cooling; in the inner flame a weak iron reaction. With soda not dissolved, but fuses to a dark yellow slaggy mass. Gelatinizes with muriatic acid.

Obs.—Occurs at Bastnäs, near Riddarhyttan, in Westmannland, Sweden, forming a bed in gneiss, and associated with mica, hornblende, copper pyrites, cerine, etc. It bears considerable resemblance to the red granular variety of corundum, but is readily distinguished by its hardness.

Hisinger and Berzelius, in 1803–4, detected in this mineral a new metal which they named *cerium*, after the planet *Ceres*, then recently announced; and the mineral they called *cerite*. Klaproth made the same discovery about the same time, and gave the name *ochroite* to the mineral, and *ochroite earth* to the new earth (alluding to its color, from ὠχρός, *brownish-yellow*). In his Beitrage, 1807, Klaproth accepted the names of Hisinger and Berzelius, yet added a syllable (lest they should appear to come from κηρα, *wax*), making them *cererium* and *cererite*—a change not accepted. In 1839 Mosander proved that the oxyd of cerium contained the new metal *lanthanum*, and in 1842 another new metal, *didymium*.

368. ERDMANNITE. *Berlin*, Pogg., lxxxviii. 162.

In imbedded grains and folia; with no traces of crystallization.

G.=3·1. Lustre vitreous. Color dark brown. In thin splinters. Translucent.

Comp.—Analysis by Blomstrand, of half a gramme (l. c.):

$\ddot{Si}$	$\bar{\bar{A}}l$	Ox. Ce & La	$\dot{F}e$	$\dot{M}n$	$\dot{Y}$	$\dot{C}a$	$\dot{H}$ and loss
31·85	11·71	34·89	8·52	0·86	1·43	6·46	4·28

Obs.—From the island Stokö in the Langesund fiord, near Brevig.

Named after Erdmann.

369. PYROSMALITE. Pirodmalit *Hausm.*, Moll's Efem., iv. 390, 1808. Wesentlicher Bestandtheil Salzsaures Eisenoxyd, *id.*, ib. (fr. blowpipe trials of Gahn, its discoverer). Pyrosmalit *Karst.*, Tab., 103, 1808; *Hausm.*, Handb., 1068, 1813. Fer muriaté *H.*, 1812, Lucas Tabl., ii. 418, 1813.

Hexagonal. *O* ∧ 1=148° 30′; *a*=0·5307. Observed planes: *O*, *I*, 1, 2 *O* ∧ 2=129° 13′, *I* ∧ *I*=120°. In prisms or tables. Cleavage: basal, perfect; *I* imperfect. Also massive. Double refraction strong, uniaxial Axis negative.

H.=4–4·5. G.=3–3·2; 3·081, Hisinger; 3·168–3 174, Lang. Lustre of *O* pearly; of other planes, less so. Color blackish-green to pale liver-brown, passing into gray and pistachio-green; usually brown externally, and light greenish-yellow internally. Streak paler than color. Fracture uneven, rather splintery. Somewhat brittle.

Comp.—O. ratio for $\dot{R}$, $\ddot{Si}$, $\dot{H}$=2 : 3 : 1; and ratio of chlorine to oxygen about 1 : 42. Making the water and chlorid of iron basic, the ratio for $\bar{R}+\dot{H}$, $\ddot{Si}$=1 : 1, and the formula ($\frac{1}{3}\dot{H}+\frac{2}{3}(\dot{R}, \text{Fe Cl}))^3\ddot{Si}$=, if Fe Cl : $\dot{Mn}$: $\dot{Fe}$ (+$\dot{Ca}$)=1 : 5 : 8, Silica 34·7, $\dot{Fe}$ 31·7, $\dot{Mn}$ 19·6, chlorid of iron 7·0, water 7·0=100. Analyses: 1, Hisinger (Afh., iv. 317); 2, same, making the iron and manganese protoxyd, and part of the iron a chlorid, and reckoning the loss as water (Ramm. Min. Ch., 675); 3, J. Lang (J. pr. Ch., lxxxiii. 424):

	$\ddot{Si}$	$\bar{Fe}$	$\bar{Mn}$	$\dot{Fe}$	$\dot{Mn}$	$\dot{Ca}$	$\dot{H}$	Cl	Fe	
1.	35·85	35·48	24·26	——	——	1·21	*undet.*	3·77	——	Hisinger.
2.	35·85	——	——	28·07	21·81	1·21	[6·29]	3·77	3·00	"
3.	35·43	——	——	30·72	20·51	0·74	7·75	3·79	——, $\bar{Al}$ 0·24	Lang.

In an earlier trial, Hisinger obtained $\ddot{Si}$ 35·40, $\bar{Fe}$ 32·60, $\bar{Mn}$ 23·10, $\bar{Al}$ 0·60, the rest undetermined.

Pyr., etc.—In the closed tube yields water, which reacts acid. B.B. fuses at 2–2·5 to a black magnetic glass. With the fluxes gives reactions for iron and manganese. A bead of salt of phosphorus, previously saturated with oxyd of copper, when fused with the pulverized mineral imparts a beautiful azure color to the flame (chlorine). Decomposed by muriatic acid, with separation of silica.

Obs.—Pyrosmalite occurs at Nya Kopparberg in Westmannland, and at Bjelkegruvan, one of the iron mines of Nordmark in Wermland, Sweden, where it is associated with calc spar, pyroxene, apophyllite, and magnetic iron. A hexagonal prism, in the museum at Stockholm, is nearly an inch in diameter and one and a quarter inches long, and weighs five and a half ounces.

Named from πῦρ, *fire*, and ὀσμή, *odor*, in allusion to the odor when heated.

370. APOPHYLLITE.

Zeolith von Hellesta *C. Rinman*, Ak. H. Stockh., 82, 1784. Zeolithus lamellaris major *Müller*, De Zeolithis Suecicis, 32, 1791. Ichthyophthalmite (fr. Utö) *d'Andrada*, Scherer's J., iv. 32, 1800, J. de Phys., li. 242, 180. Mesotype épointée (fr. Iceland) *H.*, Tr., iii. 1801. Apophyllite *H.*, Notes pour servir au Cours de Min. de l' an XIII. (1805), Lucas Tabl., i. 266, 1806. Fischaugenstein *Wern.*, 1808. Ichthyophthalmit, Albin, *Wern.*, Letztes Min. Syst., 1817. Tesselite (fr. Faröe) *Brewster*, Ed. Phil. J., i. 5, 1819. Oxhaverite (fr. Iceland) *Brewster*, Ed. J. Sci., vii. 115, 1827. Xylochlor (fr. Sicily) *v. Walt.*, Vulk. Gest., 1853. Leucocyclite *Herschell*, Descl. Min., i. 126, 1862.

Tetragonal. *O* ∧ 1-*i*=128° 38′; *a*=1·2515. Observed planes: *O*, *i-i*, *i*-2, *i*-3, 1, $\frac{1}{3}$, $\frac{1}{5}$, $\frac{1}{2}$-*i*, $\frac{1}{5}$-*i*. *O* ∧ 1=119° 30′, *O* ∧ $\frac{1}{2}$-*i*=147° 58′, 1 ∧ 1, pyr.,= 104° 2′, bas., = 121°, *i-i* ∧ *i*-3=161° 34′, *i-i* ∧ *i*-2=153° 26.′ Crystals sometimes nearly cylindrical or barrel-shape. Cleavage: *O* highly perfect; *I* less so. Also massive and lamellar.

H.=4·5–5. G.=2·3–2·4; 2·335, Haidinger, a variety from Iceland; 2·359, Thomson. Lustre of *O* pearly; of the other faces vitreous. Color white, or grayish; occasionally with a greenish, yellowish, or rose-red tint, flesh-red. Streak uncolored.
